Methods: This 3-arm, quasi-experimental study recruited 24 women-led stokvels (WLS) comprised of 8-12 members each from three socio-economically disadvantaged communities in Cape Town, South Africa. In addition to having free access to fresh produce once/month for 3-months (ZAR2000/stokvel/month), the three interventions represented last-mile distribution (LMD), voucher only (VO), and access to a market-to-table mobile application (MA). Data on collective food purchasing behaviour (FPB) of fresh produce (fruits and vegetables only) in the market was obtained through an EpiCollect survey, during a monthly shopping trip for 3 months. The user-engagement metrics of those with access to the mobile application over this period were captured. Focus group discussions (FGD) explored how having access to fresh produce without an out-of-pocket expense, provision of LMD and exposure to the mobile application impacted FPB of WLS.

Results: Shopping lists were compiled by consensus, and the first market shop focused on affordable, starchy vegetables (>kcal/ZAR). Greater diversity, variety and some “experimentation” was noted for month 2, but reverted back to original patterns in the final shop. Nutrition analysis is ongoing, with some groups spending more, but achieving a lower nutrient density than groups who spent less. We found that the average kcal (energy from fresh produce) / per ZAR over a 3-month period was 70.8. The VO group purchased fresh produce with the highest energy value/ZAR (76.4) followed by the MA group (73.6), and lastly the LMD group (70.5), but differences were NS. FGD revealed that participants experienced an improved sense of food security, expanded dietary diversity with inclusion of new foods, hedging during times of scarcity, and perceived health benefits. Individuals with access to the MA primarily viewed the recipes, with greatest engagement following the last shopping experience (14% of active daily/monthly users).

Conclusion: Logistical, educational and financial mitigation strategies can impact on healthy food choices made via WLS.

Food Is Love: The Role of Emotions in Parent-child Feeding Relationships

J. Blissett¹, K. Edwards², A. Pickard³, E. Haycraft⁴, M. Herle⁵, C. Llewellyn⁶, A. Kininmonth⁷, H. Croker⁶, C. Farrow¹

¹Aston University, Birmingham, England, United Kingdom, ²University of Birmingham, Birmingham, England, United Kingdom, ³University of Edinburgh, Edinburgh, Scotland, United Kingdom, ⁴Loughborough University, Loughborough, England, United Kingdom, ⁵Kings College of London, London, England, United Kingdom, ⁶University College London, London, England, United Kingdom, ⁷University of Leeds, Leeds, England, United Kingdom

S.1.12 Children and families: Reframing Food Parenting: Emotion, Variability, and the Next Generation of Research Auditorium, May 28, 2026, 4:00 PM - 6:00 PM

Purpose: Avid eating behaviour, characterised by higher food responsiveness, emotional overeating, and surgent temperament, is an eating behaviour profile for 20% of 3–5-year-old UK children, conferring higher obesity risk and creating challenging feeding interactions. The multi-method APPETItE project (longitudinal cohort analysis, survey, qualitative interviews, ecological momentary assessment (EMA) and a laboratory study) developed the evidence base for developing appetite-tailored interventions. However, understanding the role of parent and child emotion in feeding is core to the development of interventions that have greater chance of efficacy.

Methods: After synthesizing findings from APPETItE, we conducted workshops with parents of children with avid eating behaviour to co-create guidelines for tailored digital intervention. We undertook behavioural diagnosis using the COM-B model and identified intervention options best suited to produce the desired behaviours based on COM-B components.

Results: Evidence synthesis showed that parent and child emotion were core determinants and consequences of eating and feeding practices. Qualitative work showed that food was perceived to be effective in regulating children's emotions, and EMA demonstrated that parents were more likely to use coercive or indulgent feeding practices when they experienced higher stress and when aiming to reduce conflict. Reflective and automatic motivation were key target components. Intervention guidelines focus on creating meal and snack structure; creating a protective home food environment (availability and portioning) and developing strategies for dealing with snack food requests in the moment (delay, distract, portion). In workshops, parents fed back on the challenges of dealing with their own emotional eating, their own emotions about feeding, and their children's emotions in response to feeding practices. Food was perceived as love; regulating access to preferred food was like withdrawing joy and comfort. Emotion is a substantial barrier for parents in changing their feeding practices and home food environments.

Conclusion: Tools to support parents to create a protective food environment cannot underestimate the importance of emotion in feeding and eating. Equipping parents with the skills to reduce stress/conflict without the use of food, and to manage their own emotional eating and emotions about feeding, is a substantial challenge, but necessary to tackle to improve intervention efficacy.

S.1.12-2

Feeding Is Fluid: How Parent Characteristics, Types of Meals, and Days Shape what Children Eat

K. Loth¹, Z. Huang¹, M. Barnard¹, J. Wolfson¹, J. Fulkerson¹, N. Hogan¹, J. Fisher²

¹University of Minnesota, Minneapolis, Minnesota, United States, ²Temple University, Philadelphia, Pennsylvania, United States

S.1.12 Children and families: Reframing Food Parenting: Emotion, Variability, and the Next Generation of Research Auditorium, May 28, 2026, 4:00 PM - 6:00 PM

Purpose: Recent research shows that parents use supportive and unsupportive food parenting practices in their daily routines, challenging assumptions that they rely on a single, consistent approach. This study aimed to: (1) characterize parent-level feeding approaches encompassing a broad range of practices, (2) identify distinct patterns at the eating-occasion and day levels, and (3) examine associations between these feeding approach clusters and children's dietary intake.

Methods: Parents (n=252) of preschool-aged children (3–5 years) reported on food parenting practices used at each eating occasion (n=6,281) shared with their child across multiple days (M=9.23 days, SD=9.23). Practices were categorized into four domains: structure, autonomy support, coercive control, and indulgence. Agglomerative hierarchical cluster analysis identified clusters at the parent, eating occasion, and day levels. For each eating occasion, a Healthy Eating Index (HEI)-like score was computed (Range: 0-18; M=7.16, SD=2.30) from parent-reported child dietary intake.

Results: Four parent-level approaches emerged: Highly Involved, Mixed Structure and Indulgence, Predominantly Structured, and High Structure with Autonomy Support. At the eating-occasion level, four clusters were identified: Indulgent Leaning, A Bit of Everything, Organized or Following a Plan, and Inviting Child Participation. Parents exhibited considerable variability in feeding approaches across meals and days. The High Structure with Autonomy Support approach was associated with the most healthful child dietary intake (HEI: 0.91 higher than the least healthful approach, p=0.14), and the A Bit of Everything approach with the most healthful intake at meals (HEI: 1.01 higher than the least healthful approach, p< 0.001). Clusters differed by eating occasion (meal versus snacks), with snacks

SYMPOSIUM

generally yielding lower dietary intake scores.

Conclusion: Most parents use supportive and unsupportive food parenting practices, which cluster into distinct and meaningful patterns across parents, eating occasions and days. A High Structure with Autonomy Support approach was linked to the most healthful intake at the parent level, and an A Bit of Everything approach to meals was most favorable. These findings reveal that feeding is fluid—parents flexibly shift their approaches in response to daily contexts. Interventions that acknowledge and leverage this variability may better support healthy eating in early childhood.

S.1.12-3

Feeding Over Time: A Longitudinal Person-centered Approach to Understanding the Stability and Change in Patterns of Parents Feeding Practices

H. Povall¹, J. Blissett¹, A. Pickard², K. Edwards³, C.G. Russell⁴, K. Lacy⁴, C. Farrow¹

¹Aston University, Birmingham, England, United Kingdom, ²University of Edinburgh, Edinburgh, Scotland, United Kingdom, ³University of Birmingham, Birmingham, England, United Kingdom, ⁴Deakin University, Burwood, Melbourne, Australia

S.1.12 Children and families: Reframing Food Parenting: Emotion, Variability, and the Next Generation of Research
Auditorium, May 28, 2026, 4:00 PM - 6:00 PM

Purpose: Prior research has utilised person-centred analytical approaches to examine how parents cluster into profiles based on their feeding practices. This research has identified distinct feeding profiles distinguished by use of controlling, structure and autonomy support feeding practices. However, little is understood about how these patterns of feeding practices evolve over time. This study aimed to examine stability and transition between feeding profiles over a two-year period.

Methods: Parents of children aged 3-5 years (M=4.1 years) from the UK took part in an online survey in 2022 (Time 1), and a follow-up survey in 2024 (Time 2). Parents (n=505) completed the Comprehensive Feeding Practices Questionnaire as part of the larger APPETiTE study. Latent Profile Analysis was used to identify profiles of parental feeding practices at both time points and Latent Transition Analysis was used to examine the probabilities of parents transitioning between profiles over the two-year period.

Results: Three profiles were identified at both time points, chosen based on theoretical consideration and fit indices. Profile 1 'controlling' (T1: 33.9%, T2: 28.7%) showed high use of controlling practices and low use of structure and autonomy support practices. Profile 2 'structured and supportive' showed low use of controlling practices and high use of structure and autonomy support practices (T1: 28.3%, T2: 30.3%). Profile 3 'using everything' (T1: 37.8%, T2: 41%) showed high use of all feeding practices. Most participants remained in the same profile between time points (91%, n= 460), with particularly high levels of stability in Profile 2 and 3. Profile 1 'controlling' displayed the most movement with 11% of parents moving to Profile 3 'using everything', and 7% of parents moving to Profile 2 'structured and supportive'.

Conclusion: The number and structure of parent feeding profiles is stable across a two-year period. The 'controlling' feeding profile showed the most transitions across time, which indicates some parents are including more structure and autonomy support practices as their children get older. Understanding potential predictors of transition from the 'controlling' profile could help uncover how to best support parents with using more responsive feeding practices.

S.1.13-1

Pillars, Doughnuts, Wedding Cakes: Multidimensional Models of Sustainability and their Implications for Physical Activity

P. Gelius¹

¹Université de Lausanne, Lausanne, Switzerland

S.1.13 Policies and environments: Aligning Physical Activity Promotion with Planetary Health
Room 1, May 28, 2026, 4:00 PM - 6:00 PM

Purpose: Climate change becoming an increasingly pressing problem for global society. For physical activity, it poses a dual challenge: rising temperatures negatively impact our opportunities to be active, while our physical activity behavior contributes to global carbon emissions. This presentation aims to provide an overview of multidimensional concepts of sustainability and explore their implications for future physical activity promotion and research.

Methods: A synthesis of conceptual and theoretical frameworks of sustainability from both scientific and policy perspectives was conducted. Key models examined include the United Nations Sustainable Development Goals (SDGs) and theoretical approaches such as the pillars, doughnut, and wedding cake models. These frameworks were analyzed in relation to their potential application to PA promotion.

Results: The analysis demonstrates that sustainability in physical activity must be understood multidimensionally. Environmental sustainability requires reflection on the contributions of sport and physical activity to carbon emissions, which is challenging the current “more is better” and “do whatever you like” paradigms in physical activity recommendations.

Meanwhile, a deeper reflection of social sustainability may lead to the question of human rights in physical activity promotion and of how to achieve more equity in physical activity. Given the current state of global political affairs, this may include socially-economically disadvantaged groups but also migrants and the LGBTQ+ community.

Finally, from an economic perspective, active transport has rightfully been promoted as a type of physical activity that provides clearly measurable economic benefits to societies. Other aspects of physical activity promotion, however, continue to pose challenges, e.g. the low share of promising pilot projects that are successfully scaled up to a level where they generate actual public health benefits.

Conclusion: The findings highlight an urgent need to develop a coherent framework for sustainability in physical activity promotion, which integrates environmental, social, and economic dimensions. Such framework could navigate difficult strategic choices that have to be made in physical activity, e.g. whether to focus on adapting to climate change, to try and mitigate its impacts without harming the growth of the sport industry, or to urge the better-off members of society to limit certain physical activities for the benefit of others.

S.1.13-2

Moving More, Breathing Worse? Air Pollution Exposure and Physical Activity across Modes of Commuting in University Students

M. Herrada-Robles¹, M. Benavides-Martinez¹, X. Palma-Leal², M. Ubalde-Lopez³, S. Chastin⁴, P. Chillón-Garzon¹, P. Campos-Garzon⁵

¹PROFITH „PROmoting FITness and Health through physical activity“ Research Group, Sport and Health University Research Institute (iMUDS), Department of Physical Education and Sports, Faculty of Sport Sciences, University of Granada, Granada, Spain, ²Pontificia Universidad Católica de Valparaíso, Viña del Mar, Chile, ³Center for Research in Occupational Health (CiSAL), Universidad Pompeu Fabra, Barcelona, Spain, ⁴School of Health and life Science, Institute of Applied Health Research, Glasgow Caledonian University, Glasgow, United Kingdom, ⁵Department of Global Public Health, Karolinska Institutet, 171, Stockholm, Sweden

S.1.13 Policies and environments: Aligning Physical Activity Promotion with Planetary Health

Room 1, May 28, 2026, 4:00 PM - 6:00 PM

Purpose: This study aimed to (1) examine differences in total exposure to air pollutants (PM_{2.5} and PM₁₀) according to the mode of commuting to/from university (active vs. passive), (2) analyze the associations between minutes of moderate-to-vigorous physical activity (MVPA) and total exposure to air pollutants, and (3) compare device-measured sedentary time and physical activity (PA) levels (light PA [LPA] and MVPA) between modes of commuting.

Methods: This cross-sectional study was conducted under the MECA Project. A total of 108 university students (23.0 ± 3.9 years; 48.15% women) completed 208 valid trips to/from university. The commuting routes were tracked via GPS, as well as the mode of commuting was identified based on the mean speed of each commute recorded by the GPS. Pollutant exposure (PM_{2.5}, PM₁₀) were assessed with portable monitors, and device-measured sedentary time and PA were measured using accelerometers. Linear mixed models were conducted to analyze the differences between modes of commuting and individual exposure, sedentary time, PA levels, and to examine the association between MVPA and individual exposure. Models were adjusted for trip duration, socioeconomic status, and ambient air daily air pollutant levels.

Results: No significant differences were found in total exposure to PM_{2.5} or PM₁₀ between active and passive commuters (PM_{2.5}: active = 222 µg/m³ [95% CI: 103–340]; passive = 159 µg/m³ [95% CI: 54–264]; PM₁₀: active = 737 µg/m³ [95% CI: 198–1275]; passive = 952 µg/m³ [95% CI: 471–1432]). However, total air pollutant exposure increased

SYMPOSIUM

significantly with greater MVPA during commuting. Each additional minute of MVPA was associated with a $6.54 \mu\text{g}/\text{m}^3$ (95% CI: 1.15–11.93) increase in total PM_{2.5} exposure and a $58.94 \mu\text{g}/\text{m}^3$ (95% CI: 27.62–90.27) increase in total PM₁₀ exposure. Finally, active commuters accumulated considerably more MVPA (63.9% vs. 25.7%) and less sedentary time (23.8% vs. 57.2%) than passive commuters, while differences in LPA were not statistically significant.

Conclusion: Active commuting did not increase total air pollutant exposure but was linked to higher MVPA and lower sedentary time, indicating clear health benefits. Promoting active commuting alongside measures to improve air quality could enhance both individual and environmental health, supporting healthier and sustainable lifestyles.

S.1.13-3

Regional, Seasonal, and with Little Equipment? The German Recommendations for Physical Activity Promotion Attempt to Integrate Aspects of Planetary Health

K. Abu-Omar¹, A. Tcymbal¹, P. Gelius², S. Messing³, J. Resch¹, E. Mino¹, W. Geidl¹, K. Pfeifer¹

¹Friedrich-Alexander Universität Erlangen-Nürnberg, Department of Sport Science and Sport, Erlangen, Germany,

²Universite of Lausanne, Lausanne, Switzerland, ³University of Limerick, Limerick, Ireland

S.1.13 Policies and environments: Aligning Physical Activity Promotion with Planetary Health

Room 1, May 28, 2026, 4:00 PM - 6:00 PM

Purpose: International WHO recommendations for physical activity are grounded in the health-enhancing physical activity (HEPA) concept, which focuses primarily on human health. Growing evidence on the interconnections between physical activity and the environment (e.g., cycling offers environmental co-benefits, whereas some sports such as golf may involve high carbon emissions) suggests the need for a more holistic approach—one that encourages activities that do not unduly harm the environment.

Methods: An update of the Recommendations for Physical Activity and Physical Activity Promotion has been commissioned by the German Federal Ministry of Health. Although the update is ongoing, it provides an opportunity to introduce a paradigm shift towards a planetary HEPA concept. To inform this shift, eight semi-structured interviews were conducted with experts in nutrition (where guidelines already consider planetary-health aspects) and health ethics. Interviews explored facilitators and barriers to adopting a planetary-health perspective and, from an ethics standpoint, how such a shift can be justified.

Results: Experts emphasised that political backing is crucial for integrating planetary health into guidelines. National greenhouse-gas reduction targets were cited as important policy arguments for lowering emissions from consumption. Ethical frameworks centred on planetary health already exist and have been applied in public health and medicine. A feasible route for physical-activity recommendations would be to prioritise walking and cycling (rather than using cars) and to encourage sport and exercise that are regional (avoiding long car trips), seasonal (reducing energy demand for heating/cooling facilities), and use few equipment (minimising material impacts).

Conclusion: Integrating planetary-health considerations into physical-activity recommendations appears feasible. However, if and how to address sports with high environmental footprints remains an open question.

S.1.14-1

Prescribing Healthy Food: Results from a 12-month Randomized Controlled Trial of a Food Incentive Program for Adults with Type 2 Diabetes and Food Insecurity

D.L. Olstad¹, E. Spackman¹, R. Beall¹, S. Dunn¹, R. Oster², K. Williams³, L. Lipscombe⁴, T. Saunders-Smith¹, T. Williamson¹, S. Scott¹, S. Tariq¹, D. Campbell¹

¹University of Calgary, Department of Community Health Sciences, Calgary, Canada, ²Alberta Health Services, Edmonton, Canada, ³Alberta Health Services, Calgary, Canada, ⁴University of Toronto, Toronto, Canada

S.1.14 Cancer prevention and management: Food is Medicine Across Contexts: Clinical, Behavioral, and Implementation Evidence from International RCTs

Room 2, May 28, 2026, 4:00 PM - 6:00 PM

Purpose: The high and escalating cost of food and other necessities prevents many lower income households from accessing sufficient nutritious food—a condition known as household food insecurity. Adults living in food insecure households have poorer diet quality than their food secure counterparts and are therefore at higher risk of morbidity and mortality due to diet-related conditions such as type 2 diabetes (T2DM). Healthy food prescription incentive programs may assist adults with T2DM to adhere to a healthy dietary pattern and thereby improve their blood glucose levels and reduce diabetes complications. However, very few randomized controlled trials have examined this question. This randomized controlled trial examined the impact of a 12-month healthy food incentive program on the glycosylated hemoglobin levels (A1C; primary outcome) and clinical health markers of adults with T2DM in Alberta, Canada.

Methods: 596 adults with T2DM (baseline A1C 6.5-12%) and food insecurity were randomized to healthy food prescription incentive program (n=298) or a healthy food prescription comparison group (n=298) for 12 months. Both groups received a healthy food prescription with a diabetes-appropriate dietary pattern. The incentive group also received a weekly incentive of CDN \$10.50/household member to purchase healthy foods in supermarkets for 12 months. A1C and clinical health markers (BMI, waist circumference, blood pressure, blood lipids) were assessed at baseline and 12 months. Mixed-effects linear regression assessed between-group differences in A1C and clinical health markers, adjusted for baseline values of each outcome, randomization stratification variables and age, ethnicity, education, number of children in the home, and diabetes duration. Dose-response analyses examined whether A1C at follow-up depended on the value of incentives redeemed. Analyses were intention-to-treat, with per protocol and as-treated sensitivity analyses. Qualitative semi-structured interviews explored participants' experiences during the program.

Results: 450 adults completed 12-month follow-up (76%). Between-group differences in A1C and clinical health markers will be discussed, along with qualitative findings on participants' program experiences.

Conclusion: This was one of the largest and longest RCTs of a healthy food prescription incentive program to date. Findings can inform the design and implementation of Food is Medicine interventions worldwide.

S.1.14-2

Behavioral Mechanisms of Dietary Change: Six-month Findings from the Delta GREENS Food Is Medicine Produce Prescription Randomized Controlled Trial

M. Rahman¹

¹Tufts University, Friedman School of Nutrition Science and Policy, Boston, United States

S.1.14 Cancer prevention and management: Food is Medicine Across Contexts: Clinical, Behavioral, and Implementation Evidence from International RCTs

Room 2, May 28, 2026, 4:00 PM - 6:00 PM

Purpose: This study examined the behavioral mechanisms over 6-months that influenced the adoption of and engagement with Delta GREENS, a 12-month Food is Medicine Produce (FIM) Prescription Randomized Controlled Trial in the Mississippi Delta. This investigation identified multilevel behavioral mechanisms shaping program adoption and resource utilization, an understudied area despite growing interest in FIM interventions.

Methods: This explanatory sequential mixed methods study enrolled 50 adults from the Delta GREENS intervention arm (study target n=300, enrollment ongoing). Eligibility included Delta Health Center patients in Bolivar, Sunflower, and Washington County, age ≥25, BMI ≥25, and HbA1c 5.7-8.5%. Participants received a culturally tailored cookbook and weekly boxes of local produce valued at ~\$25. This presentation focuses on the study's qualitative findings. Using Social Cognitive Theory (SCT) as a guiding framework, semi-structured interviews at 3 (n=50) and 6 months (n=46) explored how cognitive, behavioral, and environmental factors shaped dietary behavior change. Transcripts are being deductively coded in NVivo 14 using theory-informed codebooks organized within SCT domains, with 26% double-coding to establish inter-rater reliability at each time point.

Results: Interview completion was 100% at 3 months (n=50) and 92% at 6 months (n=46). Participants were predominantly female (80%), non-Hispanic Black (80%), middle-aged to older adults (80% aged 45+) with annual household income <\$30,000 (70%) and BMI ≥30 (82%). Most reported difficulty making ends meet (68%), nutrition insecurity (64%), and 48% experienced low or very low food insecurity. Mean baseline HbA1c was 6.4% (SD=0.8, n=47). Preliminary coding suggests that dietary behavior change involves interactions across SCT domains, with environmental factors (cost, availability, convenience) intersecting with cognitive factors (knowledge, self-efficacy) and behavioral practices (cooking skills, meal preparation) shaping outcomes. Participants described how the program's ability to address multiple barriers simultaneously facilitated sustained engagement and dietary change.

SYMPOSIUM

Conclusion: Findings will elucidate behavioral mechanisms driving dietary change in FIM interventions, informing program optimization and scaling of produce prescription initiatives addressing diet-related chronic disease.

S.1.14-3

Acceptability of Medically Tailored Meals for Adults with Type 2 Diabetes in Australia: A Mixed Methods Evaluation

K.K. Law¹, J.H.Y. Wu^{1,2}, M. Gow^{1,2}, N. Ghammachi¹, K. Trieu¹

¹The George Institute for Global Health, University of New South Wales, Faculty of Medicine and Health, Sydney, Australia,

²University of New South Wales, School of Population Health, Sydney, Australia

S.1.14 Cancer prevention and management: Food is Medicine Across Contexts: Clinical, Behavioral, and Implementation Evidence from International RCTs

Room 2, May 28, 2026, 4:00 PM - 6:00 PM

Purpose: Though there is increasing rollout of medically tailored meals (MTM) interventions in the USA, their acceptability as a healthcare intervention in the Australian context is unknown. Assessing acceptability of novel interventions is crucial as it can influence their implementation and effectiveness. This interim study examined the acceptability of a 26-week MTM intervention (10 meals & ~300g nuts/week home-delivered with 3 dietitian consultations) within Australia's first MTM randomized controlled trial for adults with type 2 diabetes (T2D) and food insecurity.

Methods: Using a convergent mixed-methods design, we evaluated overall acceptability of the MTM intervention from the participants' perspective via the following outcomes: 1) perceived quality and 2) uptake of the intervention, and 3) contextual barriers and enablers influencing uptake. Between January 2023 - December 2024, quantitative (i.e. participant questionnaire and administrative records) and qualitative data (i.e. semi-structured interviews and routine monitoring questions) was collected and analysed using descriptive statistics and a deductive-inductive approach, respectively. Semi-structured interviews (n=18) provided insights on contextual factors influencing intervention uptake. Data was triangulated to gain a comprehensive understanding of acceptability.

Results: By 31 December 2024, 47 intervention participants had completed the trial. In preliminary analysis based on this sample, 74% were positive about the quality of the meals and the majority (>70%) of participants consumed an average of ≥8 (of 10) meals per week, citing convenience of the MTM intervention design as a key enabler to uptake. 70% of participants found the dietitian consultations useful, with most participants attending all three sessions (89%). Key contextual factors influencing intervention uptake included individual taste preferences and support from healthcare providers. The MTM trial was completed in October 2025. A mixed-methods process evaluation will assess the implementation, mechanisms of impact and scalability of the MTM intervention using data from the full cohort and program deliverers, with findings to be presented at the ISBNPA 2026 meeting.

Conclusion: MTM interventions are highly acceptable among individuals with T2D and food insecurity in Australia, warranting their further investigation as an innovative healthcare strategy. The upcoming process evaluation will help clarify the causal pathways and contextual factors that may influence the intervention's effectiveness.

S.1.15-1

Phase 1 of Developing a Core Outcome Set for Randomized Controlled Trials of Physical Activity Interventions for Older Adults: Knowledge Synthesis

D. Mackey¹, C. Ekegren², C. Baldwin³, P. Young¹

¹Simon Fraser University, Biomedical Physiology and Kinesiology, Burnaby, Canada, ²Monash University, Rehabilitation, Ageing and Independent Living (RAIL) Research Centre, Melbourne, Australia, ³Flinders University, College of Nursing and Health Sciences, Adelaide, Australia

S.1.15 Ageing: A New Core Outcome Set for Randomized Controlled Trials of Physical Activity Interventions that Aim to Improve the Health of Older Adults

Room 3, May 28, 2026, 4:00 PM - 6:00 PM

Purpose: To support development of a core outcome set (COS) for randomized controlled trials (RCTs) of physical activity (PA) interventions that aim to improve the health of older adults, the purpose of Phase 1 was to identify outcome domains and subdomains ('what' was measured) in previously published RCTs of PA interventions for older adults.

Methods: We conducted a rapid review and searched Ovid MEDLINE for recently-published (2015-2021), English language, RCTs of PA interventions for older adults (mean age 60+ yrs). We limited to articles published in Web of Science top-10 journals in general and internal medicine, geriatrics and gerontology, rehabilitation, and sports science. Two reviewers independently completed eligibility screening; two other reviewers abstracted trial descriptors and study outcomes. We classified study outcomes according to the outcome classification taxonomy endorsed by the Core Outcome Measures in Effectiveness Trials Initiative.

Results: Our search yielded 548 articles; 67 articles were eligible and included. Of these, 82% were efficacy/effectiveness trials, 85% included both male and female participants, and 84% recruited community-dwelling older adults. Forty percent of articles reported on interventions that involved a combination of group and individual PAs; 60% involved a combination of PA modes (e.g., aerobic, resistance). Trial sample size ranged from 14 to 2157 participants, with median (IQR) of 94 (57-517); 28,649 participants were included across all trials. We identified 21 unique outcome domains, spanning 4/5 possible core areas (physiological/clinical; life impact; resource use; adverse events). The five most commonly reported outcome domains were physical functioning (included in n=51 articles), musculoskeletal and connective tissue (n=30), general (n=26), cognitive functioning (n=16), and emotional functioning/wellbeing (n=14). Under these five outcome domains, we further identified 10 unique outcome subdomains (e.g., fall-related; body composition). No outcome domains or subdomains were reported consistently in all RCTs.

Conclusion: We found extensive variability in outcome domains and subdomains used in RCTs of PA for older adults, reflecting the broad range of potential health benefits of PA and interest to monitor possible adverse events. The inventory of outcome domains and subdomains generated by this study will inform development of a COS for RCTs of PA interventions for older adults.

S.1.15-2

Phases 2 & 3 of Developing a Core Outcome Set for Randomized Controlled Trials of Physical Activity Interventions for Older Adults: Knowledge User Perceptions

P. Young¹, C. Wallsworth², D. Mackey¹

¹Simon Fraser University, Biomedical Physiology and Kinesiology, Burnaby, Canada, ²Patient Voices Network, Vancouver, Canada

S.1.15 Ageing: A New Core Outcome Set for Randomized Controlled Trials of Physical Activity Interventions that Aim to Improve the Health of Older Adults

Room 3, May 28, 2026, 4:00 PM - 6:00 PM

Purpose: Randomized controlled trials (RCTs) of physical activity have demonstrated benefits for older adults across a wide range of health outcomes. However, little attention has been given to whether the outcomes measured are meaningful to both older adults and the healthcare professionals who support them. To support the development of a core outcome set, this sequential mixed-methods study aimed to determine which outcomes older adults (Phase 2) and healthcare professionals (Phase 3) prioritize for future physical activity RCTs.

Methods: In Phase 2, we conducted semi-structured interviews with 12 older adults aged ≥ 65 years (mean 80.1 ± 9.5 years; 6 men, 6 women) and analyzed the data using reflexive thematic analysis. Findings informed Phase 3, an online survey of 225 healthcare professionals (160 women, 55 men), including 21 physicians, 99 physiotherapists, and 105 kinesiologists, who rated and ranked the importance of 24 candidate outcome domains.

Results: Phase 2 interviews with older adults generated five outcome themes—physical, clinical, social, psychological, and overarching—each containing multiple subthemes. Participants rarely described outcomes in isolation; instead, specific outcomes were often contingent, building toward broader, holistic outcomes, with independence and quality of life emerging as the root of older adults' priorities.

Phase 3 survey results from healthcare professionals indicated that the outcome domains most frequently rated as 'highly important' were falls (92.0%), quality of life (91.5%), independence (87.9%), balance (84.4%), and mobility (82.7%). Outcome domains most frequently ranked in the top four were quality of life (67.1%), independence (50.2%), risk and management of chronic disease (40.2%), mobility (33.3%), and falls (32.9%). Healthcare professionals identified that the five outcomes most important for supporting older adult independence were strength, mobility,

SYMPOSIUM

balance, brain and cognitive, and falls, while the most important outcomes for supporting quality of life were social, psychological, mobility, brain and cognitive, and sleep.

Conclusion: Both older adults and healthcare professionals identified quality of life and independence as priority outcome domains for future research. These findings emphasize the importance of grounding physical activity RCTs in real-world impact and will help guide the development of a core outcome set that reflects patient- and provider-relevant outcomes.

S.1.15 Ageing: A New Core Outcome Set for Randomized Controlled Trials of Physical Activity Interventions that Aim to Improve the Health of Older Adults

Room 3, May 28, 2026, 4:00 PM - 6:00 PM

Purpose: The purpose of Phase 4 was to generate consensus on a core outcome set (COS) for randomized controlled trials (RCTs) of physical activity (PA) interventions that aim to improve the health of older adults.

Methods: We administered a modified Delphi process involving three rounds of online surveys to a multidisciplinary, international, expert panel comprised of researchers, healthcare professionals, and older adults. In Rounds 1 and 2, participants rated the importance of measuring a list of 27 candidate outcome domains (generated from Phases 1-3 of this project) on a 9-point Likert scale. Consistent with COS development guidelines, the threshold for consensus was defined as at least 70% of participants rating the outcome domain as 'critically important to measure' and less than 15% of participants rating the outcome domain as 'not important to measure'. In Round 3, participants ranked the importance of the outcome domains that reached consensus after Round 2 to define the final COS. To inform participant responses and guide toward consensus, participants were provided with definitions of the candidate outcome domains, evidence summaries from Phases 1-3 of this project, and results from the previous Rounds.

Results: Ninety-two participants were initially enrolled; 77 (84%) completed Round 1, and 65 (71%) completed Round 2, including 33 researchers, 17 healthcare professionals, and 15 older adults (55% female, 52% living in North America). Following Round 2, 11 outcome domains reached the threshold for consensus: 1) balance (92% rated critically important); 2) fall-related (91%); 3) mobility (89%); 4) quality of life (89%); 5) adverse events (81%); 6) cognitive functioning (81%); 7) independence (81%); 8) muscle performance (77%); 9) emotional functioning/wellbeing (75%); 10) cardiovascular and cardiorespiratory (74%); and 11) risk and management of chronic disease (71%). Results from Round 3 and the final COS will be available in early 2026.

Conclusion: The final COS will provide PA researchers with clear guidance on a minimum and standard set of outcome domains to measure and report in RCTs of PA interventions that aim to improve the health of older adults. The COS will reflect shared outcome priorities of researchers, healthcare professionals, and older adults.

S.1.16-1

Workplace Co-creation to Develop Interventions to Address Sedentary Behaviour in Scottish SMEs

M. Vogelsang¹, L. McCaffrey¹, G. C. Ryde², M. Verloigne³, M. Giné-Garriga⁴, B. McCann⁵, P. Dall¹

¹Glasgow Caledonian University, School of Health and Life Sciences, Glasgow, United Kingdom, ²University of Glasgow, School of Cardiovascular and Metabolic Health, Glasgow, United Kingdom, ³University of Ghent, Department of Public Health and Primary Care, Faculty of Medicine and Health Sciences, Ghent, Belgium, ⁴Universitat Ramon Llull, Faculty of Psychology, Education and Sport Sciences Blanquerna, Barcelona, Spain, ⁵Glasgow Caledonian University, School of Health and Life Sciences, Research Centre for Health, Glasgow, United Kingdom

S.1.16 Participatory Research in Health Promotion: The integration of co-creation, theory, and evidence in physical activity and sedentary behavior interventions: insights, recommendations, and future directions

Room 4, May 28, 2026, 4:00 PM - 6:00 PM

Purpose: Co-creation involves engaging stakeholders in developing and implementing solutions. Co-creation can produce tailored solutions that meet end-users' needs, making them more effective and sustainable. High levels of sedentary behaviour (SB) are linked to numerous health risks, with office workers particularly affected as they sit most of their workday. While participatory approaches show promise for reducing SB at work, many provide only tokenistic involvement, with researchers retaining decision-making power and limited organisational engagement. Furthermore, understanding the experience of participating in a co-creation process can enhance future experiences and engagement and help design better co-creation processes. The study aimed to advance planning, implementation and evaluation of workplace co-creation to address SB, and to explore the experiences of those engaged in the co-creation.

Methods: A co-creation process was implemented in three Glasgow small-to-medium-sized enterprises to each develop a context-specific solution for reducing SB, using a 7-step classic change management process to health (6-8 90-minute sessions per company). Sessions included creating a support base and consultation structure; mapping needs, requirements, and opportunities; drawing up and beginning action plan implementation; and evaluating and making adjustments. Evaluation involved workshop observations, co-creator evaluation forms, facilitator reflection logs, focus groups and interviews with co-creators. Both self-reported and device-based SB measures were collected. These data informed a process evaluation of the co-creation processes, including thematic analysis of focus groups, and a pre-post evaluation of SB changes. Interviews from each workplace were analysed separately using thematic analysis, and informed a cross-case comparison regarding co-creators' experiences.

Results: The study demonstrates how co-creation within SMEs can generate tailored solutions to reduce SB and foster a sense of responsibility and sustained engagement beyond formal sessions, supported by structured implementation plans. Co-creators reported a range of mostly positive experiences. Using interactive methods, skilled facilitation, and respecting co-creators' time and effort are likely to improve the co-creation experience. The implementation of the co-created solutions varied, influenced by organisational factors such as culture, managerial support, and workload pressures.

Conclusion: Co-creation can foster responsibility among employees and managers to take ownership of workplace health solutions, while cautioning against the assumption that participation automatically guarantees implementation.

S.1.16-2

Co-creation and Use of Theory for the Development of the Lifestyle Intervention Family FIT FC Targeting Football Fans and their Families

F. van Nassau¹, G.N. Muru¹, R.A. Smit¹, H.P. van der Ploeg¹

¹Amsterdam UMC, Dept. of Public and Occupational Health, Amsterdam, Netherlands

S.1.16 Participatory Research in Health Promotion: The integration of co-creation, theory, and evidence in physical activity and sedentary behavior interventions: insights, recommendations, and future directions

Room 4, May 28, 2026, 4:00 PM - 6:00 PM

Purpose: The effective European Football fans in Training (EuroFIT) lifestyle intervention showed how the power of football can be used to make a sustainable change in the lifestyle of male football fans. Following this success, football clubs expressed an interest in developing a lifestyle intervention for football fans and their families. Therefore, building on the theory of EuroFIT, and in co-creation with the club, coaches, children and their parents, a new intervention was developed and pilot tested: Family FIT FC.

Methods: First, a behavior change model was developed for both the children and their parents, guided by the Self Determination Theory. Next, this theory was translated into practical sessions, during many co-create sessions with the coaches of the clubs and club representatives. Next, three 2-hour taster sessions were organized to pre-test specific aspects of the intervention. Researchers observed the sessions to gather feedback from participants. After each session, a reflective group discussion was held with the participants and coaches to evaluate the activities of the sessions. Next, all feedback was used to develop the final materials for the pilot evaluation.

Results: The co-creation process has resulted in a 12-week intervention for children between 12-17 years and their parents. The co-creation guided the selection in age of children, as well as the target behaviors. For example coping with stress and sleep were added as targets behaviors. The initial theory of the program was 'simplified' by the

SYMPOSIUM

coaches to tailor it to the available time, level of the participants, as well as feasibility to deliver. In total, 4 families participated in the pilot. The pilot delivery showed promising results on health behaviors, but also showed room for improvement towards the content of the program.

Conclusion: Building on the evidence of its processor EuroFIT, we were able to co-create and pilot a first draft of the Family FIT FC intervention. The synergy between researchers and coaches in the development has resulted in a theory-based intervention that is implementable in practice. The intervention was further adapted in co-creation with the coaches and is currently being evaluated in 2 clubs.

S.1.16-3

Recommendations and Best Practices for the Integration of Co-creation, Theory, and Evidence in Health Behavior Interventions: Results from Expert Interviews

B. Victor¹, A. D'sa², Y. Oldert³, S. Compennolle¹, M. Verloigne⁴, G. Cardon¹

¹Ghent University, Department of Movement and Sports Sciences, Ghent, Belgium, ²Technological University of The Shannon, Department of Sport and Health Sciences, Athlone, Ireland, ³Amsterdam UMC Location Vrije Universiteit Amsterdam, Department of Public and Occupational Health, Amsterdam, Netherlands, ⁴Ghent University, Department of Public Health and Primary Care, Ghent, Belgium

S.1.16 Participatory Research in Health Promotion: The integration of co-creation, theory, and evidence in physical activity and sedentary behavior interventions: insights, recommendations, and future directions

Room 4, May 28, 2026, 4:00 PM - 6:00 PM

Purpose: School-going children and adolescents currently fall short of adhering to physical activity, sedentary behavior, and sleep guidelines, suggesting that current interventions are not sufficient. Research demonstrates that co-creation, theory, and evidence can bolster the effectiveness of interventions, but the integration of these approaches presents challenges. In previous studies, co-creation, theory, and evidence were used to develop interventions, but using disparate approaches. For example, some studies use a classic theory (such as Self-Determination theory) to generally ground the intervention, while others use an intervention planning approach (such as the Behavior Change Wheel) to structure the entirety of the intervention development. Even within studies that use similar approaches, researchers co-create with the target group at different steps of intervention development and report varying degrees of detail about the integration. Thus, there is a need for insights into how researchers can best combine co-creation, theory and evidence in health behavior interventions.

Methods: Expert interviews have thus far been conducted with 8 researchers—4 experts in behavior change theory, 2 researchers who have previously combined these approaches in intervention development, and 2 experts in co-creation. Interviews were transcribed and analyzed using semantic thematic analysis.

Results: All interviewed experts acknowledged the benefits of combining co-creation, evidence, and theory, but noted practical difficulties when combining a top-down and a bottom-up approach such as how to involve the target group in the more theoretical aspects of the respective approach. To fill this gap, all experts advocated for some form of guidelines and/or recommendations to guide future researchers who aim to integrate these approaches. In addition, experts emphasized the benefit of using an intervention planning approach such as the Behavior Change Wheel or Intervention Mapping (in which theory and evidence are included) to structure the co-creation sessions, but noted that recommendations should be applicable to different planning approaches. Finally, experts suggested the need for specific reporting guidelines when combining these approaches.

Conclusion: Based on the results of expert interviews, a draft of recommendations and best practices will be formulated to assist researchers, which will be recirculated to experts for feedback and presented at the ISBNPA 2026 conference.

S.1.17-1**Strategic Adaptation: Engaging Context to Strengthen Public Health Nutrition Impact****C. Byker Shanks¹**¹Center for Nutrition & Health Impact, N/A, Omaha, United States**S.1.17 Motivation and behavior change: Science or Strategy? Public Health Nutrition's Compass in a Polarized World****Room 5, May 28, 2026, 4:00 PM - 6:00 PM**

Purpose: Nutrition and health outcomes are shaped by food environments, including what foods are stocked in stores, served in schools, and promoted through marketing. These environments reflect cultural norms and policy choices that influence what is considered normal, affordable, and/or desirable to eat. Presenting evidence alone often does not shift dietary patterns or generate lasting support for nutrition policy. This presentation argues that adjusting communication, framing, and collaboration to reflect the priorities of the setting in which a public health nutrition initiative is being implemented can strengthen adoption and effectiveness. Here, strategic adaptation is presented as a practical approach for improving impact while maintaining scientific standards.

Methods: This argument draws on public health ethics principles including transparency (clearly stating evidence and uncertainty), role clarity (speaking as a public health practitioner versus political actor), and proportionality (aligning advocacy with the strength of evidence). Research on trust in nutrition communication shows that people interpret information through identity and values, and that messages gain traction when they connect with widely shared concerns. Two cases will be discussed: initiatives to limit ultra-processed foods in school meals and fruit and vegetable incentive programs through USDA GusNIP. These examples show how communication strategies and collaboration with established organizations influence understanding, support, and participation.

Results: Program experience indicates that nutrition efforts are more successful when framed around priorities such as children's growth, food costs, and familiar food practices. Working with organizations that already hold trust in a community increases acceptance and engagement. When public health does not adapt how it communicates, commercial marketing and competing narratives often fill the gap and shape eating behaviors in ways that undermine health. These patterns appear across regions and countries with varying cultural and political orientations, suggesting that strategic adaptation improves communication without requiring alignment with any stance.

Conclusion: Strategic adaptation helps public health improve the reach and sustainability of nutrition programs. When guided by ethical principles and clear communication of evidence, adaptation strengthens trust and supports effective implementation. To improve food environments and health outcomes, public health nutrition must participate in the conversations and decisions that shape everyday eating conditions.

S.1.17-2**Public Health Nutrition Must Defend Science, Institutions, and Democracy When Health Is Politically Undermined****A. Troen¹**¹The Hebrew University of Jerusalem, Institute of Biochemistry, Food Science, and Nutrition, Rehovot, Israel**S.1.17 Motivation and behavior change: Science or Strategy? Public Health Nutrition's Compass in a Polarized World****Room 5, May 28, 2026, 4:00 PM - 6:00 PM**

Purpose: This presentation argues that in an era of democratic backsliding and politicization of science, public health nutrition can no longer rely on neutrality and strategic communication alone. Across diverse contexts—including the United States, Israel, Hungary, Argentina, Brazil, and Turkey—science, surveillance systems, and academic institutions are being weakened or politicized. The purpose is to examine whether public health nutrition should remain strictly apolitical or adopt a principled, politically aware stance to

Methods: The argument draws on global case examples where public health and nutrition policy were shaped not by miscommunication, but by deliberate political interference. These include: repeal or obstruction of sugar-sweetened beverage (SSB) taxes in the USA and Israel; cancellation of the USDA Food Security Survey and weakening of NHANES; political debates on withdrawal from WHO; Hungary's takeover of its Academy of Sciences. These examples are

SYMPOSIUM

analyzed through public health ethics—scientific rigor, transparency, equity—and democratic theory concerning the role of institutions, accountability, and the public good.

Results: These cases reveal that “Adaptation” is not enough. The central challenge is not failure to communicate evidence but the erosion of foundational assumptions of modern public health, and in particular public health nutrition. Evidence is cynically dismissed as ideological, uncertainty is weaponized, and health becomes a partisan identity marker. Remaining neutral can mean silence while institutions are dismantled. Yet full political alignment risks partisanship, loss of trust, and moral overreach. The key insight: the risk is not being political—the real risk is being partisan, opaque, or self-righteous.

Conclusion: Adaptation and cultural sensitivity remain important, but they are insufficient when science and democracy are under attack. Public health nutrition must learn to engage as a principled civic actor—defending evidence, democratic institutions, and human dignity—without becoming partisan. This requires naming when science is misused, when vulnerable populations are harmed, and when institutions are weakened, while remaining grounded in transparency, humility, and service to all. Only by doing so can public health and public health nutrition uphold its role in a free and truth-based society.

S.1.18-1

From System Mapping to Systemic Action: Building the Food System Transformation Solution Bank Tool

K. Parsons¹, A. Bladon²

¹University of Cambridge, Epidemiology Unit, Cambridge, United Kingdom, ²University of Reading, Reading, United Kingdom

S.1.18 Systems Science: Catalyzing System Change: From Understanding Complexity to Taking Action

Room 6, May 28, 2026, 4:00 PM - 6:00 PM

Purpose: There is a proliferation of research, policy and practice activity taking place, trying to identify ‘what can we do’ to address food systems challenges, including complex public health problems. Often such projects begin with a system mapping exercise to identify key challenges or leverage points for targeted actions, and methods to do this are well developed and increasingly implemented. However, methods for solution identification and selection are less well developed, and potential solutions are fragmented, in silos related to a particular system activities, outcomes and type of lever. Because this presents a barrier to taking systemic action, we developed a tool to aid solution scanning, based on an approach pioneered in the field of conservation science.

Methods: A two-stage workshop co-design process, involving participants from multiple academic disciplines and areas of food system expertise, was developed and delivered. Sources of solutions were harvested, and a classification scheme co-designed and tested. Solution sources were reviewed and data extracted and coded, supported by a taxonomy, which was iterated during data coding and in pilot applications. A review of additional classifications was conducted, to provide users with a menu of further classifications which could be built into any solution scanning process.

Results: From 277 sources, including reports, academic literature and policy databases, we extracted 3,485 potential solutions for transforming the food system. Every solution was tagged according to five classifications. To facilitate use we developed an open access online interface with search functionality.

Conclusion: The Food System Transformation Solution Bank contributes a practical tool, a method for solution scanning, and knowledge of the types of sources, classifications and solutions which exist. The database is freely available for use by researchers, policymakers and practitioners, and can be used to create long-lists of solutions - categorized with descriptive tags - for further analysis, and application of additional criteria. What started life as a simple database project resulted in a package of tools: the database itself - in excel and web form - a food system solution taxonomy, a review and typology of potential criteria which can be applied, and a method for harvesting and coding sources.

S.1.18-2

From Insights to Action: Using Systems Archetypes to Transform Hospital Food Environments

M.FM van den Heuvel¹, W.E Waterlander², J.WJ Beulens³, L. Crielaard², J.R O'Mara², H.M Kruizenga⁴, J.M Stuber³, SC. Dijkstra¹

¹Amsterdam UMC Location Vrije Universiteit Amsterdam, Public and Occupational Health, Amsterdam, Netherlands,

²Amsterdam UMC Location University of Amsterdam, Public and Occupational Health, Amsterdam, Netherlands,

³Amsterdam UMC Location Vrije Universiteit Amsterdam, Epidemiology and Data Science, Amsterdam, Netherlands,

⁴Amsterdam UMC Location Vrije Universiteit Amsterdam, Nutrition and Dietetics, Amsterdam, Netherlands

S.1.18 Systems Science: Catalyzing System Change: From Understanding Complexity to Taking Action

Room 6, May 28, 2026, 4:00 PM - 6:00 PM

Purpose: Despite growing commitment to healthy and sustainable food environments, many hospital food environments for staff and visitors remain dominated by unhealthy and unsustainable options. Systems archetypes may help explain why well-intended interventions often fail and reveal leverage points where strategic action can shift system behaviour. This study applies systems archetypes within a Group Model Building approach to identify recurring patterns that hinder change and to co-develop leverage-based strategies for lasting improvement in hospital food environments.

Methods: Two Group Model Building workshops were conducted with 36 representatives from key stakeholder groups at a major Dutch university hospital. In the first workshop, stakeholders collaboratively mapped factors sustaining the current food environment. Researchers then constructed a Causal Loop Diagram, used systems archetypes to identify recurring patterns, and identified leverage points from the systems archetype literature. In the second workshop, these prescribed leverage points guided the co-development of stakeholder-informed action strategies.

Results: Three recurring patterns emerged; (1) *Shifting the Burden*: reliance on short-term solutions limiting structural change; (2) *Success to the Successful*: unequal playing field among food providers limiting the growth of healthier offerings; and (3) *Limits to Success*: stagnant demand for healthy and plant-based foods constraining further investment and adoption. *Shifting the Burden* appeared as the central dynamic, while the other systems archetypes depended on its structural conditions. Accordingly, the resulting action strategies prioritized (1) addressing root causes by strengthening organizational structures and capacities, then (2) levelling the playing field for food providers, and finally (3) addressing underlying constraints to shift demand.

Conclusion: Systems archetypes provide an innovative, structured approach to move from understanding systemic frictions to identifying actionable strategies. By revealing where and how to intervene, they help accelerate the transition toward healthy and sustainable hospital food environments. The insights and methods presented here can guide similar food environment transitions across healthcare and other institutional settings.

S.1.18-3

The Qualitative Systems Exploration Model (QSEM): Helping Practitioners and Policy-makers Move from Causal Loop Diagrams to Actionable Insight

A. Hulme¹, D. Radley², A. Brown³, J. Rajah⁴, B. Kopainsky⁴, L. Crielaard⁵, H. Koorts⁶, J. Nobles⁷

¹The University of Queensland, Southern Queensland Rural Health, Briabane, Australia, ²Leeds-Beckett University, School of Sport, Leeds, United Kingdom, ³Deakin University, Institute for Health Transformation, Deakin, Australia, ⁴University of Bergen, Department of Geography, Bergen, Norway, ⁵Amsterdam UMC, Department of Public and Occupational Health, Amsterdam, Netherlands, ⁶Deakin University, Institute for Physical Activity and Nutrition (IPAN), Deakin, Australia, ⁷Leeds-Beckett University, School of Health, Leeds, United Kingdom

S.1.18 Systems Science: Catalyzing System Change: From Understanding Complexity to Taking Action

Room 6, May 28, 2026, 4:00 PM - 6:00 PM

Purpose: Causal Loop Diagrams (CLDs) are increasingly used to depict and understand complex systems driving the major public health issues of the 21st century.

Challenges often arise when moving from understanding [the system] to action. The Qualitative Systems Exploration Model (QSEM) provides a semiquantitative framework for interpreting and analysing CLDs to help identify points of interest for action. We draw on its application in a commissioned project exploring population dietary intake in Wales.

SYMPOSIUM

Methods: We worked with Welsh Government stakeholders to test and refine QSEM via facilitated in-person and online workshops. A base CLD of the Welsh food system was created through a synthesis of nine existing maps, refined through one in-person group model building workshop and 10 smaller online workshops. A final workshop with 17 policy officials provided impact- (i.e. the influence one variable has on another) and control- (i.e. Welsh Government ability to influence) values for all interconnections within the CLDs, referred to as System Factor Classification (Phase 1). The research team used QSEM to analyse these values, and identify Loops of Interest (Phase 2) and System Archetypes (Phase 3). Given the extensiveness of the Welsh food system, the food production sub-system illustrates the utility of QSEM.

Results: The food production sub-system included 29 factors. We noted six pertinent feedback loops (four reinforcing and two balancing) which explain how the environmental impact of food production and consumer demand can facilitate farming practice diversification, how increased food production may increase food waste, and how the volume of food produced in Wales is limited by its processing capacity. QSEM highlighted that Just in Time processing and consumer demand were important factors to focus on, whilst the cost of food, farming practice diversification, and environmental impact were factors to measure progress against. Phase 3 revealed a 'shifting the burden' archetype.

Conclusion: QSEM provides a systematic, transparent process for interpreting and analysing CLDs. In this proof-of-concept testing, QSEM enabled stakeholders to critically examine their CLD and generate tangible, actionable insights. Since finalising this project, QSEM now has a dedicated software solution to expand its utility in qualitative systems dynamics modelling.

S.1.19-1

Monitoring Physical Fitness in Preschoolers: An Essential Step for Early Health Promotion

C. Cadenas-Sanchez¹

¹University of Granada, Physical and Sports Education, Granada, Spain

S.1.19 Motivation and behavior change: From Playground to Adulthood: The Lifelong Impact of Physical Fitness
Room 7, May 28, 2026, 4:00 PM - 6:00 PM

Purpose: To examine the longitudinal associations between physical fitness at preschool age and cardiometabolic and mental health outcomes during adolescence, within the PREFIT-UP study.

Methods: The PREFIT-UP project builds upon the Preschoolers' Fitness Test (PREFIT) project, which primarily aimed to develop a standardized battery to assess physical fitness in preschool children aged 3–5 years. A total of 3,169 preschoolers (47.2% girls) were initially evaluated between 2014 and 2015. Preschoolers were assessed by using the PREFIT battery: i) anthropometry: weight, height, and waist circumference, ii) cardiorespiratory fitness (PREFIT 20m shuttle run test), iii) muscular strength: upper-limbs muscular strength (handgrip strength) and lower-limbs muscular strength (standing broad jump), and iv) speed-agility (PREFIT 4x10m shuttle run test). In 2024–2025, we are conducting a follow-up assessment approximately 9–10 years later, expecting to include around 1,000 adolescents. At follow-up, cardiometabolic health outcomes include intermuscular fat quantified via ultrasound at the thigh level, body fat mass (bioimpedance), arterial stiffness by using the assessed using a validated non-invasive oscillometric system, and continuous glucose monitoring (24h/day for 7 consecutive days). Mental health outcomes include behavioral and emotional problems and perceived stress levels via validated questionnaires for adolescents.

Results: Preliminary analyses in a subsample indicate no significant longitudinal association between preschool fitness levels and continuous glucose profiles during adolescence. However, data collection and analyses are ongoing, and broader associations with other cardiometabolic and mental health indicators will be explored as follow-up assessments progress.

Conclusion: Monitoring fitness from early childhood provides valuable insight into the developmental origins of health and disease. PREFIT-UP uniquely bridges preschool and adolescent stages, highlighting the relevance of early-life fitness as a potentially modifiable factor for long-term cardiometabolic and psychological well-being. This study will contribute critical longitudinal evidence to inform early prevention and health promotion strategies.

S.1.19-2

Exploring Lifelong Physical Fitness Journey with SLOfit

G. Jurak¹¹University of Ljubljana, Faculty of Sport, Ljubljana, Slovenia

S.1.19 Motivation and behavior change: From Playground to Adulthood: The Lifelong Impact of Physical Fitness
Room 7, May 28, 2026, 4:00 PM - 6:00 PM

Purpose: This study's primary purpose is to leverage Slovenia's unique, national SLOfit physical fitness monitoring system to investigate the pathway of fitness from childhood into adulthood and explore causal relationships between longitudinal fitness trajectories and adult health outcomes. The research innovation lies in utilizing data collected since 1987 through the SLOfit Students program (ages 6–18) and integrating it with new tracking from the SLOfit Adults program, providing an unprecedented, decades-long, cohort-based dataset for lifespan health analytics.

Methods: This is a quantitative, retrospective cohort study built upon the SLOfit national fitness monitoring infrastructure. The system incorporates a citizen science approach and is supported by the My SLOfit web application (275,000 registered users = 14% of Slovenian population), which provides individualized health risk/benefit feedback based on evidence-based centile curves and health benefits associated with scores in certain fitness components.

Participants: A sample of approximately 1,000 SLOfit members will be analyzed, focusing on individuals currently aged 35–55 years.

Measures: Childhood/Adolescent Fitness: historical data collected via the Sport Educational Chart battery; Adult Fitness: current fitness levels measured using the Physical Fitness of Adults' battery; Lifestyles: historical and current lifestyles identified through validated questionnaires; Health Outcomes: identified health outcomes in adulthood.

Results: The data collection and merging with previous testing are currently underway, and results are forthcoming. The analytical plan focuses on advanced statistical modeling (e.g. LMMs, MSMs, GMM) to map the trajectory of fitness components over the lifespan and to explore the causal effect of fitness levels during key developmental periods (childhood, adolescence, young adulthood, mid-age adulthood) on later-life fitness and established health outcomes. Preliminary analyses will focus on establishing the direct and indirect predictive power of childhood fitness scores on measured adult fitness and health indicators, controlled for lifestyles characteristics.

Conclusion: Specific findings are expected to elucidate crucial critical periods in the lifespan where interventions on physical fitness offer the greatest protective benefits against adverse health outcomes in middle age, providing evidence-based support for public health policy and the continuous use of the SLOfit system.

S.1.19-3

Health-related Physical Fitness Test Battery in Adults: The ADULT-FIT Study

M. Cuenca García^{1,2}

¹University of Cadiz, Department of Physical Education, Faculty of Education Sciences, Cádiz, Spain, ²Instituto de Investigación e Innovación Biomédica de Cádiz (INIBICA), Cadiz, Spain

S.1.19 Motivation and behavior change: From Playground to Adulthood: The Lifelong Impact of Physical Fitness
Room 7, May 28, 2026, 4:00 PM - 6:00 PM

Purpose: Physical fitness is a well-established predictor of morbidity and mortality in adults, highlighting its value as an indicator for public health monitoring. Several field-based physical fitness test batteries have been proposed for adults; however, none of them meet the essential measurement quality criteria, including health-related predictive validity, criterion validity, reliability, feasibility, safety, and responsiveness. The aim of the ADULT-FIT study was to propose a health-related field-based physical fitness test battery for adults based on scientific evidence.

Methods: The ADULT-FIT research team reviewed the scientific evidence on the health-related predictive validity, criterion validity, reliability, feasibility, and safety of field-based physical fitness tests in adults, and conducted six systematic reviews and two meta-analyses. The research team also conducted several methodological studies to determine the criterion validity and reliability of various field-based fitness tests in a sample of 410 adults aged 18–64 years, homogeneously distributed by sex, age, and physical activity level. Moreover, the feasibility and safety items identified in the scientific evidence were evaluated for the selected tests. Finally, the research team examined the responsiveness of the selected tests after a 12-week multicomponent exercise training program involving 62 inactive participants aged 18–64 years, who were randomly assigned to either an intervention ($n=31$) or control group ($n=31$).

SYMPOSIUM

Results: The selected health-related field-based physical fitness tests for adults (18-64 years) that met the essential measurement quality criteria were: (1) the 20mSRT (as high priority) to assess cardiorespiratory fitness, the 6-minute walk and 2-km walk tests could be an alternative in adults whose fitness level is low or who find it difficult to run; (2) the handgrip strength (as high priority) and sit-to-stand (i.e., 30-seconds/5-repetitions) tests to assess muscular strength; (3) the 6 meter walk test to assess motor fitness; and (4) body mass index and waist circumference (as high priority), and skinfold-based equations to measure body composition. This proposal could be adapted according to age group.

Conclusion: The ADULT-FIT health-related field-based fitness test battery is valid, reliable, feasible, safe, and responsive for assessing physical fitness in adults (18-64 years), and can be effectively used for health monitoring purposes.

S.1.20-1

Current Approaches to Physical Activity Policy Evaluation: A Comparative Analysis of International Tools

S. Messing¹, K. Volf¹, C. Woods¹

¹University of Limerick, Physical Activity for Health Research Centre, Health Research Institute, Department of Physical Education and Sport Sciences, Limerick, Ireland

S.1.20 Policies and environments: From Monitoring to Action: Advancing Knowledge on Physical Activity Policy Practice and Implementation

Room 8, May 28, 2026, 4:00 PM - 6:00 PM

Purpose: In policy evaluation research, the limited attention of decision makers and the insufficient use of evaluation results have been described as key problems. To address these issues, various tools have been developed in the field of physical activity to support the translation of research evidence into policy. This study analyses established international tools for monitoring or evaluating physical activity policies and compares their strategies for influencing policy processes.

Methods: A two-step data collection approach was employed. First, relevant tools were identified through existing systematic reviews and targeted hand searches of the scientific literature. Second, twelve semi-structured interviews were conducted with experts involved in the development or application of these tools. Thematic analysis was used to explore key aspects of policy monitoring and evaluation.

Results: Eight international tools for monitoring and evaluating physical activity policies were identified. Thematic analysis revealed two distinct evaluative approaches: deficit-based strategies, which emphasize identifying gaps and shortcomings in policy, and strength-based strategies, which focus on showcasing good practice and fostering cross-country learning. These approaches differ in their intended use of evaluation results and in their communication strategies.

Conclusion: This study highlights the diversity of evaluative strategies in the field of physical activity policy. While the relevance and applicability of individual tools may vary across national and cultural contexts, reflecting on the strengths and limitations of different approaches can enhance their utility. Promoting interdisciplinary collaboration and tailoring evaluation strategies to specific policy contexts may improve the uptake of evidence and increase the impact of evaluations on policy development.

S.1.20 Policies and environments: From Monitoring to Action: Advancing Knowledge on Physical Activity Policy Practice and Implementation

Room 8, May 28, 2026, 4:00 PM - 6:00 PM

Purpose: Effective policy action is vital to promote population-level physical activity. European governments have introduced dozens of policy initiatives that potentially impact the activity levels of their citizen populations but the extent of policy implementation across Europe remains poorly understood. This study aims to provide a comprehensive overview of national physical activity policies and their implementation in six European countries by developing 'evidence documents' that detail government actions across multiple domains.

Methods: An audit of national-level physical activity policies was undertaken by research teams in Germany, Ireland, Lithuania, Poland, the Netherlands and Romania. In four of these countries information on policies, surveillance and funding was available from a prior audit using the HEPA PAT. All research teams accessed government websites to identify evidence of policies. Policy documents were read and specific actions were mapped onto the 45 indicators of the PA-EPI framework. The audit was followed up with extensive snowballing to identify evidence of policy implementation. Researchers conducted internet searches and contacted professionals with domain-specific expertise to identify whether any further evidence was publicly available. Researchers then shared draft evidence documents with policymakers across different government departments via online questionnaires for validation and held in-person meetings to gather feedback.

Results: Validated evidence documents were completed for all six countries. Policymaker engagement during validation enhanced evidence document accuracy and comprehensiveness, and final documents are being prepared for dissemination to national stakeholders. The descriptions of policy implementation suggest considerable variation in policy implementation across the domains of the PA-EPI.

Conclusion: This study delivers the first multi-country collation of evidence of policy implementation using the PA-EPI framework enabling holistic policy assessment and cross-country comparison. This research fits into a broader process of coalition formation, policy assessment and advocacy that has the potential to support improved policy effectiveness.

S.1.20 Policies and environments: From Monitoring to Action: Advancing Knowledge on Physical Activity Policy Practice and Implementation

Room 8, May 28, 2026, 4:00 PM - 6:00 PM

Purpose: Physical activity (PA) policies operate across multiple levels of governance and sectors, and subnational actors (e.g., regions, municipalities) are predominantly responsible for implementation. The Physical Activity Policy Environment Index (PA-EPI) provides a tool to assess the extent of implementation of national-level PA policies. However, it remains unclear whether and how the PA-EPI should be adapted for subnational contexts. This study analyses existing subnational PA policy monitoring tools and discusses whether their characteristics support the need for a subnational adaptation of the PA-EPI.

Methods: A systematic gray literature review was conducted, as government-developed monitoring tools are often not described in peer-reviewed publications. Steps included: (1) reference screening of existing reviews, (2) gray literature search in the data bases OpenGrey and Startpage, and (3) expert consultation. Tools were included if they were explicitly designed to collect data on PA-related policies at subnational levels. The following data were extracted: governance level targeted (regional/local), domains and indicators covered (e.g., education, sport), data collection

SYMPOSIUM

methods, evidence sources, frequency of monitoring, number of items, stakeholder involvement, and output.

Results: This review identified 17 tools that monitor, assess or benchmark PA policies at subnational level. Nine were developed by researchers, while eight can be described as government-driven. The methodology of data collection differs; while the majority of tools are based on surveys, some utilize desk-research in combination with expert consultation. Moreover, most tools were sector-specific (e.g., active transport, urban design) and primarily descriptive, documenting the presence of policies or environmental aspects rather than systematically assessing the extent of implementation in comparison to best practice. None of them is based on a comparable set of indicators and/or a comparable process as the PA-EPI.

Conclusion: The review indicates clear gaps in existing subnational PA policy monitoring approaches, particularly regarding comprehensiveness, assessment of implementation, and structured stakeholder involvement. While the PA-EPI is a validated tool for evaluating PA-related government action at the national level, a direct transfer to the subnational level may require adaptation, capacity building, and dedicated resources. The development of a subnational PA-EPI may be beneficial to complement strategies to support PA policy implementation at subnational levels.

S.1.21 Policies and environments: Environmental correlates of physical activity in Europe: an OBCT symposium
Room 9, May 28, 2026, 4:00 PM - 6:00 PM

Purpose: To systematically review and synthesise the evidence on socioeconomic inequalities in neighbourhood environmental resources that promote physical activity (PA) across different life stages in high-income countries.

Methods: In February 2024, we systematically searched Medline, Embase, Web of Science Core Collection, and Scopus. Eligible studies were quantitative primary research articles published in English that examined objectively measured neighbourhood PA-promoting environments in relation to at least one individual- or area-level socioeconomic indicator. Titles and abstracts were screened with ASReview, and full texts were screened manually in duplicate. Data were extracted with a predefined form, and risk of bias was assessed with an adapted version of the AXIS tool. We synthesised our findings narratively and by reported proportions of associations indicating disadvantaged exposure, advantaged exposure, or no statistically significant difference for people with lower SEP.

Results: A total of 250 studies were included. Overall, people with lower SEP were more likely to live in areas with (components of) walkable and bikeable infrastructure, and to have playgrounds nearby, but less likely to have access to formal sports and PA facilities. For other PA-promoting environments, findings were largely null. Patterns varied across age groups, study regions, statistical approaches, and SEP indicators.

Conclusion: Populations with lower SEP were more exposed to walkability components, bikeability, and playgrounds, but less exposed to sports and PA facilities. Advantages and disadvantages for populations with lower SEP vary by PA resource and SEP indicator, and also by country, age group, and unit of analysis. Throughout both the main analyses and stratified analyses, null results remain common. Overall, these findings imply that socioeconomic inequalities in exposure to PA environments are nuanced rather than uniform. This complexity highlights the need to consider multiple environmental features together and to tailor equity-focused interventions to local contexts.

S.1.21-2

Data Source Availability and Validation of Sports Facilities Across Socioeconomically Diverse Areas in Europe: A Geographic Information Systems-based OBCT Study

R. Valiente¹, V. Cuenca¹, J. Diez¹, L. Cereijo¹, N. Patel², M. Raju², J. Lakerveld²

¹University of Alcalá, Alcalá de Henares, Spain, ²Amsterdam UMC, Amsterdam, Netherlands

S.1.21 Policies and environments: Environmental correlates of physical activity in Europe: an OBCT symposium
Room 9, May 28, 2026, 4:00 PM - 6:00 PM

Purpose: Reliable geospatial data are essential to assess physical activity and obesogenic environments, yet ensuring data consistency across multinational projects remains challenging. Research has traditionally relied on administrative datasets, which are often incomplete or unavailable in some regions, undermining data comparability. The recent expansion of geospatial big data has introduced alternative sources that may help reduce socioeconomic gaps in data availability and coverage. However, these sources still differ in collection methods, purposes, and spatial scope. Using Geographic Information Systems (GIS), we aim to identify relevant data sources on sports facilities and evaluate their agreement across socioeconomically diverse neighbourhoods in Madrid (Spain).

Methods: We obtained data on the location of sports facilities from three sources: administrative records (AR), commercial data from Google Maps (GM), and volunteered data from OpenStreetMap (OSM). We assessed agreement between GM or OSM and AR (reference) using container- and gravity-based approaches. The container-based approach compared the number and location of facilities per census tract/postcode, estimating sensitivity, positive predictive value, and concordance. The gravity-based approach used GIS techniques to generate density surfaces of facility availability for each source, which were then compared to identify spatial discrepancies. Finally, multilevel regression models examined differences in agreement across socioeconomic strata within each case-study area.

Results: The number of facilities varied markedly by data source, with GM generally reporting higher volumes than OSM. OSM better captured outdoor facilities, while GM performed better for indoor and private ones. Agreement varied spatially, and therefore socioeconomically, since outdoor facilities often concentrated in urban outskirts and low-density, green neighbourhoods. Associations between agreement and SES were mixed, depending on the data source. For instance, GM sensitivity varied from 0.55 in low-SES to 0.70 in high-SES tracts. However, OSM showed higher sensitivity across low SES than high-SES areas (0.46 vs 0.21).

Conclusion: Commercial and volunteered datasets may complement administrative data where lacking, but structural and socioeconomic biases must be carefully considered. These biases may distort analyses of sport facility access and associations with health outcomes, potentially misleading evidence for equitable policy-making. Robust validation is therefore crucial. Ongoing work is expanding this preliminary study to additional regions in Europe.

S.1.21 Policies and environments: Environmental correlates of physical activity in Europe: an OBCT symposium
Room 9, May 28, 2026, 4:00 PM - 6:00 PM

SYMPOSIUM

Purpose: To determine the association between objectively measured neighbourhood walkability and device-measured physical activity (PA) behaviours in adults across Europe.

Methods: This cross-sectional study uses data from multiple cohorts, including UK Biobank (UK), NNPAS2 (Norway), NAKO (Germany), SCAPIS (Sweden), and the Portuguese PA and sports monitoring systems. In total, approximately 170,000 adults aged 18 years and older will be included. These cohorts are enriched with individual-level information on a high-resolution walkability index recently developed for Europe.

Walkability index was calculated within a 15-minute street-network buffer for each participant using their residential address, based on 100 m × 100 m grids. The index components are street walk length, street intersections, green space, slope, public transport stops, land use mix, 15-minute walking isochrones, and daily amenities. The index is calculated separately for each country and ranged from 0-100 (least to most walkable).

PA behaviours were measured with accelerometers. The primary outcome was step count (steps/day). Secondary outcomes included total PA, light PA, and moderate- to- vigorous PA, and sedentary time (minutes/day).

Multivariable linear regression models were used to assess the cohort-specific associations between neighbourhood walkability and PA, adjusting for age, sex, education level, employment status, household income, degree of urbanisation, and timing of PA measurement as putative confounding sources. Next, the effect estimates will be pooled via random-effect meta-analysis.

Results: Preliminary results from Portuguese (n= 2,554) and Norwegian (n= 4,661) cohorts:

In Portugal, the mean residential walkability score was 67.1 (SD=21.5), and participants' mean step count was 7,950 (SD=3,830) steps/day. In Norway, the mean walkability score was 61.1 (SD=21.6), and step count was 8,310 (SD=3,140) steps/day. Higher walkability was positively, though not statistically significant, associated with step counts in both countries, Portugal: $\beta = 8.1$ (95% CI = -4.0; 20.2), Norway: $\beta = 2.53$ (95% CI = -3.83; 8.89).

Conclusion: Higher neighbourhood walkability indicated higher step count per day in two medium-sized cohorts. Future analyses will incorporate larger-sized cohorts from UK, Germany, and Sweden; exploring secondary PA outcomes, assessing potential effect modifiers, and evaluating varying walking distance buffers. This Europe-wide multi-cohort study provides evidence linking standardised and objective neighbourhood walkability to device-measured PA behaviours across diverse populations.

S.1.22-1

Foodways of the Urban Poor in South Africa: A Pathway to Dietary Interventions

F. Wayas¹, O. Alaba², A. Fawole³, R.V. Dover⁴, A. King⁵, E.V. Lambert^{1,6}

S.1.22 Socio-economic inequalities: What it takes to address food insecurity, improve nutrition, and address diet-related chronic disease: Innovative global perspectives

Multipurpose Room, May 28, 2026, 4:00 PM - 6:00 PM

Purpose: Unhealthy diets and urbanisation, influenced by various social determinants of health, are key contributors to the rising prevalence of non-communicable diseases (NCDs) and obesity in South Africa, especially among the urban poor. Food is fundamental to life and health, and has social, cultural, and personal meanings which may vary and impact on health. Recognizing and understanding the *foodways*, i.e. the cultural, physical, environmental, social, and economic practices that impact food choices and habits is critical to inform the development of context-specific interventions that promote food as medicine. The objective of this study was to use the lived experience exploration to better understand the factors that influence *foodways* of the urban poor.

Methods: Thirty-four adults (21-45 years old) of both genders residing in a South African, low-income community, and who were primarily responsible for food decisions in their households, were purposively recruited for this ethnographic cross-sectional study. We conducted in-depth interviews, and participants completed a Neighbourhood Discovery Walk, using the Our Voice Citizen Science method, to characterise the local food environment that shaped their food choice decisions. Data were audio-recorded, downloaded, and transcribed and thematically analysed.

Demographic characteristics and anthropometric measurements were also collected.

Results: Participants were mostly women (>75%) with a moderate-high prevalence of overweight/obesity (>50%), food insecurity (>50%) and hypertension (45%). We identified four primary themes with sub-themes that highlight physical, behavioural, socio-cultural and economic constraints that were associated with participants' foodways. Our study suggests that economic limitations, household and cultural norms (such as large food portion size, hospitality, food brands, and preference for meat-based "proper" meals) are important factors to consider in developing sustainable interventions to promote healthy eating. Food sourcing and procurement were beyond logistical decisions; issues of personal safety and the provision of credit influenced food procurement. While participants spoke about healthy food meaning, food quality and nutritional labelling were often not taken into consideration, whereas the expiry dates did warrant attention.

Conclusion: Understanding these foodways relationships are essential for designing equitable, culturally responsive, and sustainable urban food systems, especially in low and middle income countries.

S.1.22-2

Feasibility and Acceptability of Personalised Medical Nutrition Therapy Plus Food Prescription to Those with a Diabetes-related Foot Ulceration - A Pilot Randomised Controlled Trial (RCT)

C. Collins^{1,2}, P. Tehan^{3,4}, E. Clarke^{1,2,5}, D. White⁴, K. Phillips⁶, C. Sankoorikal⁷, J. Hawkins⁸, M. Kris⁸, H. Donnelly^{1,2,3}

¹University of Newcastle, School of Health Sciences, Callaghan, Australia, ²Hunter Medical Research Institute, Food and Nutrition Research Program, Rankin Park, Australia, ³Monash University, School of Clinical Sciences, Melbourne, Australia, ⁴John Hunter Hospital, High Risk Foot Service, New Lambton Heights, Australia, ⁵Hunter Medical Research Institute, Food and Nutrition Research Program, Callaghan, Australia, ⁶Tamworth Hospital, High Risk Foot Service, North Tamworth, Australia, ⁷John Hunter Hospital, Department of Endocrinology, New Lambton Heights, Australia, ⁸Hunter New England Local Health District, Greater Newcastle Sector Diabetes Service, Newcastle, Australia

S.1.22 Socio-economic inequalities: What it takes to address food insecurity, improve nutrition, and address diet-related chronic disease: Innovative global perspectives

Multipurpose Room, May 28, 2026, 4:00 PM - 6:00 PM

Purpose: Diabetes-related foot ulcers (DFU) are a major diabetes complication with inadequate nutrient intakes adversely impacting wound healing. DFU complications place substantial physical, emotional and financial burden on individuals and their families. These individuals are more likely to experience socioeconomic disadvantage, food insecurity and live with multiple comorbidities. Previous trials have utilised nutrient supplements. However, the role of medical nutrition therapy (MNT) delivered by dietitians, supplemented with a food prescription has not been evaluated in this population. Furthermore, food items that contain key nutrients needed for wound healing can be expensive or unfamiliar for people living with DFU.

Methods: A 6-week pilot RCT was conducted at two high-risk foot clinics. Diet quality was assessed pre-post RCT using the Australian Eating Survey food frequency questionnaire. MNT was provided to the intervention group at baseline, and weeks 2 and 4 with food boxes provided at baseline and week 4. Both groups received a (AU)\$25 grocery voucher at each time-point. Food security was assessed using the United States Department of Agriculture six-item Food Security Module.

Results: Ten intervention participants and seven control participants completed the pilot trial. Significant between group differences were identified for protein, vitamin A and vitamin B12. Significant within group differences were found for the intervention group with an increase in protein, fibre, dairy serves, vitamin A and magnesium. One-third of participants reported low or very low food security, with the mean index of relative socioeconomic advantage and disadvantage of 3.41 (SD 2) indicating most participating lived in areas classified as disadvantaged. All intervention participants reported the food boxes helped manage their overall living expenses, increased their knowledge of foods important for wound healing, while liking the items provided in the food box.

Conclusion: Personalised MNT and food prescription was acceptable for those with DFU, and improved some aspects of diet quality, which may have onward effects including addressing food insecurity, improving wound healing and overall health.

S.1.22-3

Designing, Implementing, and Evaluating Food Is Medicine to Improve Food Security, Diet, and Diet-related Conditions in Diverse Communities in the US

L. Rosas¹, W.-t. Chen², L. Xiao², A. Marti², M. Radtke², E. Van Blarigan³, S. Piawah⁴, J. Tester⁵

¹Stanford University, Stanford Prevention Research Center, Palo Alto, United States, ²Stanford University, Epidemiology and Population Health, Palo Alto, United States, ³University of California San Francisco, Epidemiology, San Francisco, United States, ⁴University of California San Francisco, Oncology, San Francisco, United States, ⁵University of California San Francisco, Pediatrics, Oakland, United States

S.1.22 Socio-economic inequalities: What it takes to address food insecurity, improve nutrition, and address diet-related chronic disease: Innovative global perspectives

Multipurpose Room, May 28, 2026, 4:00 PM - 6:00 PM

Purpose: Over 18 million households in the US can be classified as food insecure, defined as a lack of consistent access to nutritious food for an active and healthy life. Those that experience food insecurity are disproportionately impacted by diet-related chronic conditions like heart disease and diabetes. Food is Medicine, refers to nutrition interventions that are implemented in healthcare to address the interrelated challenges of food insecurity, suboptimal diet, and diet-related chronic conditions. We will describe lessons learned about design, implementation, and evaluation from three Food is Medicine studies that were tailored to different patient populations.

Methods: The three studies used a participatory research orientation. First, we will describe the design phase of CART (Cancer Survivor Nutrition Assistance Research Trial), an intervention for cancer survivors that included nutrition education and vouchers for home-delivered medically supportive groceries. We conducted four focus groups (n=34) and a pilot test (n=40) with cancer survivors to design the intervention. Second, we will describe the implementation phase of Vida Sana y Completa, an intervention tailored for Latina women at risk for diabetes (n=412) that included a culturally tailored behavioral lifestyle intervention and medically supportive groceries provided by the local food bank. Third, we will share evaluation outcomes from Recipe4Health (n=4271), a produce prescription program for primary care patients with diet-related chronic conditions.

Results: Lessons learned in the design phase for CART included the importance of social support for eating healthy, need for trusted and tailored nutrition education, and high acceptability of home delivered groceries. In the implementation phase for Vida Sana y Completa, we learned the importance of cultural tailoring of groceries and nutrition information for Latina women and flexibility in delivering the intervention including via telehealth. Evaluation of Recipe4Health underscored the need to triangulate electronic health record data, surveys, and qualitative interviews to understand impact.

Conclusion: Building on lessons learned in the individual projects, we identified common themes across projects including the importance of tailoring for specific patient populations, matching the intensity of the Food is Medicine program to the acuity of patient needs, and the importance of nutrition education to maximize effectiveness.

S.2.23-1

Designing Places *for and with* Children and Adolescents

J. Schipperijn¹, C. Pawlowski¹

¹University of Southern Denmark, Sports Science and Clinical Biomechanics, Odense, Denmark

S.2.23 Children and families: Designing outdoor play spaces *for and with* children: integrating participation, green design, and municipal processes

Auditorium, May 29, 2026, 8:00 AM - 9:00 AM

Purpose: The majority of children and adolescents are not meeting physical activity recommendations. Part of the reason for this is the lack of suitable outdoor spaces for children and adolescents aged 9-15 to meet, play and be active together. We pose that truly listening to children and adolescents and actively involving them in designing outdoor spaces will increase their use of outdoor spaces, and with that, increase their physical activity and well-being.

Methods: We have compiled our knowledge and evidence from six studies in Denmark. In each of the mixed-methods studies, we looked at changes in the use of outdoor space by 9-15-year-olds. We used different types of co-creation processes in each study to re-design the outdoor spaces based on the wishes and ideas from the 9-15-year-olds. Using structured observations as well as combined accelerometer and GPS data, we identified which type of features

were used for different behaviours. Based on go-along interviews, we identified different types of children, as asked them about their respective outdoor spaces feature and activity preferences.

Results: To stimulate (active) use by 9-15-year-olds, outdoor spaces should contain a variety of features. They should include secluded social areas where they can hang out with each other, preferably younger children should not have access to these areas, and teachers and other adults should not directly look out on them. Furthermore, there should be areas with age-appropriate physical challenges such as high climbing frames, or other equipment that is physically challenging and creates a feeling of risk-taking.

Sports features such as ball game areas, as well as features for non-competitive activities are also important. Finally, it is important that there is a good balance between paved and more natural, vegetated surfaces.

Conclusion: If outdoor spaces include secluded hang-out areas for social activities, areas with age-appropriate physically challenging features that are experienced as risky, as well as sports area, and areas for non-competitive activities, 9-15 years-olds are likely to use them actively, which positively influences their well-being and total daily physical activity levels.

S.2.23-2

Integrating Co-creation into Municipal Design Processes for Public Playgrounds: Lessons from 24 Dutch Municipalities

T. ten Tije¹, I. Huiberts¹, A. Singh¹

¹Mulier Institute, Utrecht, Netherlands

S.2.23 Children and families: Designing outdoor play spaces for and with children: integrating participation, green design, and municipal processes

Auditorium, May 29, 2026, 8:00 AM - 9:00 AM

Purpose: Co-creation in the design of public playgrounds is essential to ensure that these spaces meet the needs of children, parents, and neighbours, thereby stimulating their use. Although the benefits of co-creation are well known, integrating it into the design processes of public playgrounds remains challenging. This difficulty arises from conflicting structures and practices between co-creation approaches and traditional municipal design procedures. In this project, we developed a co-creation process for stimulating outdoor play and supported 24 municipalities in the Netherlands in implementing this process. We evaluated the implementation of the co-creation process in these municipalities and the experiences of the involved stakeholders.

Methods: We conducted several interviews with local project teams during and after the project. In addition, we analysed project documents, such as project plans and meeting minutes, and collected additional observations through regular meetings with the project managers who supported the local project teams. We deductively analysed data from each municipality to identify successes, barriers, and lessons learned, and subsequently performed a cross-case analysis to reveal patterns and differences across municipal contexts.

Results: Preliminary results show that the level of co-creation varied across municipalities. Openness of local stakeholders to learn, and the involvement of all relevant municipal actors from the start, contributed to a more comprehensive co-creation process. In contrast, limited time availability among project teams and pre-existing neighbourhood planning and policy procedures constrained the co-creation process. Contextual factors influencing the course of the project included the size of the municipality and the department in which the local project leader worked. Overall, local project teams reported that the co-creation process was highly valuable, as it was more inclusive and participatory than their usual practices. Despite the project being designed to align with municipal procedures, some teams experienced the process as time-consuming and were hesitant to integrate it into standard practice.

Conclusion: Having a co-creation process that aligns with municipal procedures supports successful co-creation in the design of public playgrounds. However, fully embedding such processes within municipal practices requires time, learning, and firsthand experience of the benefits of co-creation.

⁴Deakin University, School of Exercise and Nutrition Sciences, Melbourne, Australia

S.2.23 Children and families: Designing outdoor play spaces for and with children: integrating participation, green design, and municipal processes

Auditorium, May 29, 2026, 8:00 AM - 9:00 AM

Purpose: Children spend large amounts of time at school yet many school yards lack green space such as trees and gardens. Retrofitted school greening may positively impact play and physical activity. This review aimed to examine the effects of primary school greening interventions on student's physical activity and school-based free play. It is part of a larger "Green Schools" study that is examining the impact of adding new green spaces in four mainstream and specialist primary schools in Melbourne Australia on physical activity and well-being compared to control schools.

Methods: The review was conducted in accordance with the PRISMA guidelines. An electronic search of databases including Scopus, EBSCOHost (via MEDLINE Complete, GREENFile, ERIC, and Environment Complete) and EMBASE was conducted in December 2024. Key inclusion criteria: interventional or experimental study design at a primary school with or without a control group, greening installations explicitly stated as part of the intervention/experiment, quantitative pre- and post-greening measurement of student's school-based free play or physical activity. Resultant articles from the final search were imported into Covidence. Quality assessment was performed using the McMaster Quality Assessment tool. The "Green Schools" methodology will be described as part of this presentation.

Results: Out of a total of 14,770 screened articles, nine studies met the eligibility criteria. They were conducted in three countries (US, UK and the Netherlands) and published between 2014-23. Four studies had more than one intervention school and eight studies had a control school. A range of greening interventions were included, including greening installations only, greening + interactive components (e.g., gardening lessons), and greening + play structure renovation. Follow-up periods ranged from 3-months to two years post baseline, and 55% were rated as strong quality. MVPA increased at follow-up at intervention schools in four studies, with stronger effects reported among girls compared with boys in three studies. Only one study examined play behaviours.

Conclusion: Methodological variations were observed between the studies. Further research is required to examine the impacts of pre-and-post greening interventions on physical activity in primary school-aged children in Australia.

S.2.24 Policies and environments: Advancing Equity in Food and Physical Activity Policy: Strategies, Participatory Approaches, and Evaluation

Room 1, May 29, 2026, 8:00 AM - 9:00 AM

Purpose: 'Upstream' policies addressing unhealthy food environments, such as marketing restrictions on unhealthy products, are known to prevent non-communicable disease more effectively than 'downstream' policies targeting individual behaviours. Proposals for such policies, despite their effectiveness, often meet significant resistance, including by industry actors. This systematic review aims to identify strategies and tactics that have been successfully

employed by non-commercial actors to facilitate the adoption of policies for healthy food environments.

Methods: We undertook a systematic review and best-fit framework synthesis based on a pre-registered protocol (<https://osf.io/hcgs4/>). We searched five databases (Medline, Embase, Web of Science, PsycINFO, and the International Bibliography of the Social Sciences) for qualitative studies examining processes and factors leading to the adoption of public policies for healthy food environments at local, regional, national, or supranational levels, in high- or middle-income countries. We screened 20% of abstracts in duplicate in Rayyan and the remainder using ASReview's machine learning algorithm. We assessed all full-texts in duplicate and drew on the WCRF NOURISHING framework to categorise policies. Data analysis used our previously developed *a priori framework* as the initial coding frame. This was subsequently revised and expanded through inductive thematic analysis.

Results: We included 68 articles which covered 79 distinct policy processes in 37 countries. Policies adopted in North America (n=26), the Western Pacific region (n=18) and Latin and South America (n=14) were most commonly examined, in particular SSB taxation (n=37) and front-of-pack labelling (n=10). The adoption of sugar taxation in Mexico was covered in five articles. We identified five principal strategies facilitating adoption: political advocacy, intra-political tactics (i.e. tactics only available to political actors), coalition-building, media advocacy and community mobilisation. Across these five principal strategies, framing, using and generating evidence, resources and capacity-building, and analysis and deliberate action were employed as cross-cutting strategies. For example, political context analysis and information about possible opposition to policy proposals informed both political and media advocacy.

Conclusion: Our work intends to inform public health advocates about strategies and concrete tactics that have positively influenced policy adoption of policies promoting healthy food environments.

Systemic Change for Equitable Healthy Diets: A Participatory Systems Approach with Citizens and Stakeholders in Lower-income Neighbourhoods in Four European Countries

S.K. Djojoseparto¹, N. Sonneveld¹, J. Harrington², M. Steele², N. O' Connor², P. Romaniuk³, K. Kaczmarek³, K. Alcer³, N. Zadworna³, E. Van Duin⁴, J. Van Kerckhove⁵, G. Cardon⁴, S. Vandevijvere⁵, C. Kamphuis⁶, M.P. Poelman¹

S.2.24 Policies and environments: Advancing Equity in Food and Physical Activity Policy: Strategies, Participatory Approaches, and Evaluation

Room 1, May 29, 2026, 8:00 AM - 9:00 AM

Purpose: Socioeconomic inequalities in health and diet persist and have widened across Europe, with lower-income groups facing disproportionate risks of poor health outcomes. These disparities are not only ethically concerning but also represent a significant economic burden, with EU estimates suggesting up to €72 billion in annual efficiency gains from reducing health inequalities. Unhealthy diets are a key contributor to these health disparities, shaped by broader social determinants such as poverty, discrimination, and unequal access to resources. This study aimed:

1. To gain insight into the complex system of factors that influence dietary behavior among people living on a low income, - from the perspective of both citizens with experiential knowledge and professionals in four European communities.
2. To identify systemic leverage points and policy actions to promote healthier dietary behaviour among people living on a low income, based on insights from both citizens with experiential knowledge and professionals in four European communities.

Methods: This study adopts a systems-based participatory approach to map the complex drivers of dietary behaviour among people living on low incomes in four European communities: the Netherlands (Ede, Veldhuizen), Ireland (Togher, Ballyphehane, Cork City Southside), Poland (Zabrze), and Belgium (Ghent). Group Model Building sessions were conducted with citizens with lived experience and professionals from health and social sectors, resulting in country specific causal loop diagrams that were integrated into one causal loop diagram that identifies nine interconnected domains: government and policy, food industry, socio-cultural factors, food environment, living conditions, socio-demographic determinants, wellbeing, individual behaviour, and macro-level structural drivers.

Results: Four key dynamics emerged: (1) framing, power, and policy; (2) socioeconomic disadvantage and wellbeing;

SYMPOSIUM

(3) food environment; and (4) socio-cultural context. These dynamics interact, thereby increasing the susceptibility to unhealthy dietary behaviours among people living on a low income and perpetuating cycles of inequality. By integrating experiential and professional insights, this study identifies systemic leverage points and policy actions to promote healthier dietary behaviours among low-income populations.

Conclusion: The findings offer a European food policy perspective on the structural and systemic roots of diet-related inequalities, highlighting the need for multi-level, inclusive interventions to address the root causes of health disparities.

S.2.24-3

Systematically Integrating Equity in Physical Activity Policy Recommendations

F. Heuvelman¹, P. Gelius², E. Garcia Bengoechea³, S. Messing^{3,4}, C. Woods³, N. den Braver¹

S.2.24 Policies and environments: Advancing Equity in Food and Physical Activity Policy: Strategies, Participatory Approaches, and Evaluation

Room 1, May 29, 2026, 8:00 AM - 9:00 AM

Purpose: Physical activity (PA) policies are increasingly recognized as essential to improving population health, and many countries have established formal PA policies. However, major gaps remain in how equity is addressed in PA policy processes, with few practical and systematic methods or tools available to embed and evaluate it. Building on the Physical Activity Environment Policy Index (PA-EPI), this study aims to explore and test approaches to systematically integrate equity considerations into PA policy, enabling the identification of policy recommendations that are both relevant, feasible and equitable.

Methods: During a workshop with a diverse group of Dutch equity experts forming a PA-EPI equity council (n=11), two potential ways of integrating equity in the formulation of policy recommendations were explored: (1) Problem and solution tree analysis to identify structural drivers of inequities and link them to actionable solutions within existing structural domains of the PA-EPI (finance, governance, etc); and (2) Prioritisation and reformulation of prior policy recommendations from a PA-EPI council of PA experts in the Netherlands to incorporate an equity lens. Subsequently, we performed a process evaluation, based on a structured questionnaire, examining facilitators and barriers in integrating equity as part of the PA-EPI process.

Results: 1) Identified problems included fragmented policies, limited policymaker insight on vulnerable groups, poor cross-sector integration, difficult access to subsidies, lack of policy continuity, and insufficient inclusion skills among PA professionals. Broader system-level drivers were identified as root causes of inequities, e.g. outcome-driven policies focusing on easily measurable results (e.g. participation numbers), rather than equitable outcomes. 2) Prioritising and reformulating PA-EPI recommendations by equity experts indicated strong alignment with priorities identified in the earlier PA-EPI expert council, enhanced the inclusiveness of the recommendations, and helped identify key themes to inform the integration of equity considerations across policy recommendations. The process evaluation indicated that equitable facilitation, clear goals, structure through framework, expertise diversity were facilitative. Barriers included building from pre-existing recommendations (semantics, perceived lack of comprehensiveness), and substantial time investment.

Conclusion: This study produces equity-integrated policy priorities for the Netherlands and methodological insights to systemically integrate equity in PA policy evaluation.

S.2.25-1

Why Physical Activity Micropatterns? Concept, Epidemiological Evidence, and Bespoke Research Framework

E. Stamatakis¹, N. Koemel¹

¹The University of Sydney, Sydney, Australia

S.2.25 Motivation and behaviour change: Physical activity micropatterns: A stealth lifestyle factor with the potential to support sustainable habit formation interventions?

Room 2, May 29, 2026, 8:00 AM - 9:00 AM

Purpose: Traditional physical-activity research and guidelines have focused on total weekly volumes of moderate-to-vigorous activity, derived from self-report data that capture mostly amounts of structured exercise and other long physical activity sessions. With the advent of high-resolution wearable devices and machine-learning analytics, it is now possible to examine micropatterns, defined as brief, incidental bouts of moderate-to-vigorous intensity (10 seconds – 3 minutes each) embedded in daily life. This presentation addresses three linked aims: (1) describe the conceptual basis for focusing on physical-activity micropatterns; (2) summarise the emerging epidemiological and evolutionary evidence linking these micropatterns to health outcomes; and (3) propose a micropatterns research framework that can guide future measurement, epidemiology, intervention and translation work.

Methods: Evidence is drawn from recent large-scale, device-based prospective studies using 10-second resolution accelerometry (e.g., UK Biobank, NHANES). These analyses quantify associations between intensity-specific micropatterns and major health outcomes (cardiovascular disease, cancer, all-cause mortality). This work is complemented by a consortium of cohorts that compare high-resolution physical activity patterns between modern hunter gatherers and western high income populations.

Results: Across multiple studies, even small daily amounts of incidental vigorous activity were associated with substantially lower risk of CVD and cancer. These effects persist among adults who report no structured exercise. Observational evidence from modern hunter-gatherer populations suggests that frequent short bursts mirror evolutionarily normal movement behaviour, offering a biologically and behaviourally congruent model for sustainable activity promotion. Considering the nascent nature of this work, a bespoke research framework is required.

Conclusion: Wearables-revealed micropatterns represent a shift in physical-activity science, broadening how we conceptualise, measure, and prescribe movement. They hold promise for reaching the 80–85% of adults who remain insufficiently active, by reframing health-enhancing movement as brief, opportunistic, and universally attainable. Integrating micropattern evidence into future guideline updates, behavioural interventions, and digital-health platforms could yield a more inclusive, scalable, and evolutionarily aligned approach to chronic-disease prevention and population wellbeing.

S.2.25-2

Understanding Vigorous Intermittent Lifestyle Physical Activity (VILPA) in Physically Inactive Midlife Women: Insights from Co-creation, Accelerometry, and Qualitative Inquiry

M. Eghøj¹, A. Rijal¹, J. Heidler¹, C. Bjørk Petersen², J. Arvidsen¹, C. Thøgersen-Ntoumani¹

S.2.25 Motivation and behaviour change: Physical activity micropatterns: A stealth lifestyle factor with the potential to support sustainable habit formation interventions?

Room 2, May 29, 2026, 8:00 AM - 9:00 AM

Purpose: Vigorous Intermittent Lifestyle Physical Activity (VILPA) represents short bouts of vigorous movement embedded in daily life, such as stair climbing or brisk walking uphill. Although epidemiological evidence demonstrates strong protective health effects, little is known about how inactive populations perceive and engage in VILPA. This study explored behavioural determinants of VILPA among Danish midlife women to inform the design of a mobile health intervention.

Methods: A mixed-methods, theory-informed co-design was conducted. Data comprised:

- (a) two rounds of co-creation workshops with 42 physically inactive women aged 40–65 years;
- (b) seven-day accelerometer measurements in 20 women with no prior knowledge of VILPA; and
- (c) post-measurement focus-group interviews (5 interviews, 2–7 participants per group).

Data were thematically analysed using a critical-realist approach and mapped to the COM-B model and Behaviour Change Intervention Ontology (BCIO).

Results: Co-creation workshops revealed strong preferences for interventions that are simple, time-efficient, and identity-congruent, with digital prompts and habit-supporting features. Accelerometer data indicated that most participants already engaged in spontaneous VILPA bouts, typically 1–4 episodes per day lasting 30–119 seconds. Focus-group interviews identified key barriers (low perceived capability, uncertainty about intensity, fear of injury)

SYMPOSIUM

and motivators (convenience, reframing everyday movement, social reinforcement, and sense of achievement).

Conclusion: Findings highlight that VILPA is both feasible and appealing for inactive midlife women when framed as purposeful, achievable movement. Interventions should emphasise habit formation, contextual prompts, safety reassurance, and positive identity alignment to enhance uptake and sustainability.

S.2.25-3

Multi-centre Randomised Controlled Feasibility Testing of a Wearable-based Micropatterns Intervention and International Adaptation

N. Koemel¹, M. Bissett², G. Ryde², M. Ahmadi¹, K. Atsiaris¹, I. Chen¹, A. Teixeira-Pinto¹, S. Liu³, C. Maher⁴, K.H. Chong¹, A. Bauman¹, M. Sawan¹, C. Thøgersen-Ntoumani⁵, C. Gray², J. Gill², E. Stamatakis¹

¹The University of Sydney, Sydney, Australia, ²The University of Glasgow, Glasgow, United Kingdom, ³University of Victoria, Victoria, Canada, ⁴University of South Australia, Adelaide, Australia, ⁵University of Southern Denmark, Odense, Denmark

S.2.25 Motivation and behaviour change: Physical activity micropatterns: A stealth lifestyle factor with the potential to support sustainable habit formation interventions?

Room 2, May 29, 2026, 8:00 AM - 9:00 AM

Purpose: This randomised controlled study evaluated the feasibility, acceptability and potential effectiveness of a co-designed wearable-based micropatterns intervention aimed at increasing moderate-to-vigorous physical activity (MVPA) among socioeconomically diverse women.

Methods: A multi-centre 6-week randomised controlled feasibility study was conducted among women from Sydney, Australia and Glasgow, UK aged ≥30 years who self-reported no leisure time physical activity and could comfortably participate in activities of daily living. To ensure socioeconomic diversity, we used quota-based recruitment with area-level and individual-level indicators of socioeconomic status. Participants were randomised to one of three intervention arms; 1) Smartphone application only (APP); 2) smartphone application combined with a wearable device (Fitbit Inspire 3; W-APP); and 3) smartphone application and wearable device, supplemented by a social community component that included two in-person workshops and online forums (W-APP-C). Feasibility was assessed as completion rates of the study and follow-up surveys were conducted to assess the acceptability of the intervention. Wrist-worn accelerometry was collected at pre- and post-intervention to assess the potential effectiveness of the intervention.

Results: Forty-three participants (mean age (SD); 54.8 (10.7) years) were recruited across both sites (APP n = 13; W-APP n = 17; W-APP-C n = 13). When taking into consideration individual-level indicators of socioeconomic status including income, number of dependents, and educational attainment, there was diverse representation across low (20.9%), medium (48.8%), and high (30.2%) socioeconomic groups. Completion of the 6-week intervention was high across both intervention sites and all three trial arms (86%). Qualitative feedback from both trial sites indicated high satisfaction, the majority of the participants thought the intervention was enjoyable (97.9%), user-friendly (69.9%), the wearable technology increased motivation to do activity (87.5%), and the community workshops were beneficial (75%). Across all participants, there was an average daily increase of 9.8 (27.8) min/day MVPA following the intervention. The greatest increase in MVPA was observed in the W-APP-C group (15.5 (23.1) min/day), followed by the APP group (11.4 (25.5) min/day), and the W-APP group 2.6 (32.1) min/day.

Conclusion: This multi-centre randomised controlled feasibility trial highlights the feasibility and acceptability of a wearable-based micropattern intervention in women from socioeconomically and culturally diverse backgrounds.

S.2.26-1

Participatory Research with Key Stakeholders in Urban and Rural Areas: Lessons Learned from Applying a System Dynamics Approach to Promote Healthy School Environments in Ecuador

A. Ochoa-Avilés¹, J. Ocaña², C. Ochoa-Avilés¹

¹Universidad de Cuenca, Department of Bioscience, Cuenca, Ecuador, ²Pontificia Universidad Católica del Ecuador, Instituto de Salud Pública, Quito, Ecuador

S.2.26 Participatory Research in Health Promotion: Participatory research with children and stakeholders: challenges and lessons for promoting healthy eating in Latin America

Room 3, May 29, 2026, 8:00 AM - 9:00 AM

Purpose: Designing health promotion strategies for complex problems requires the active involvement of all relevant stakeholders. We conducted participatory workshops with key stakeholders in urban and rural communities in the Andean region of Ecuador, using systems thinking to (1) develop causal-loop diagrams (CLD) of the causes and consequences of unhealthy school food environments, and (2) prioritize relevant and feasible interventions.

Methods: Four participatory workshops were conducted between April and May 2025 in both urban and rural communities in Ecuador, following a predefined script based on group model-building techniques. Thirty-six participants, including representatives from the ministries of health and education, school officials, teachers, mothers, fathers, school kiosk staff, NGO representatives, researchers, and local government members, with support from the research team, created a CLD of the causes and consequences of unhealthy school food environments. Afterwards, potential intervention sites were identified, and the participants proposed prioritized health promotion strategies.

Results: In both urban and rural areas, stakeholders agreed that unhealthy family habits are reinforced by a lack of nutrition education and aggressive marketing for ultra-processed products. This impacts children's preferences and fosters unhealthy school environments. Rural participants highlighted that a deterioration of community networks also affects family habits and children's preferences. Urban stakeholders emphasized the importance of advocacy and citizen involvement, particularly with academic support, to promote healthy school food policies. Rural participants highlighted the role of local governments in supporting school gardens. Stakeholders agree that poor school food environments increase the risk of malnutrition, mental health issues, chronic diseases, and learning disorders.

In rural areas, strategies focused on improving farming techniques, encouraging healthy eating habits, and conserving local culinary traditions were emphasized. Urban stakeholders prioritized regulating the marketing of ultra-processed products, promoting nutritional education, and supporting healthy eating marketing campaigns.

Conclusion: This research offers insights for implementing culturally relevant strategies tailored to the local context, incorporating social, individual, and environmental factors, with a focus on families, to prevent the marketing of ultra-processed products and promote knowledge and healthy habits. These should be supported by policies developed in collaboration with the community and academic input, involving local governments.

S.2.26-2

From Children's Ideas to National Impact: A Co-designed Front-of-Pack Warning Label Campaign with Measurable Effects among Mexican Youth

A. Jáuregui¹, S. Pacheco Miranda², K.L. Quevedo¹, C.I. Oviedo Solis¹

¹Instituto Nacional de Salud Pública, Department of Physical Activity and Healthy Lifestyles, Cuernavaca, Mexico,

²Instituto Nacional de Salud Pública, Cuernavaca, Mexico

S.2.26 Participatory Research in Health Promotion: Participatory research with children and stakeholders: challenges and lessons for promoting healthy eating in Latin America

Room 3, May 29, 2026, 8:00 AM - 9:00 AM

Purpose: In 2020, Mexico implemented front-of-pack warning labels (FOPWLs) to help consumers identify and reduce purchases of products high in added sugars, sodium, and saturated fats. We co-designed a communication campaign to promote FOPWL use among Mexican children and youth, which was later implemented by UNICEF and the Ministry of Health. This presentation describes the co-design process, the resulting campaign and implementation, and its impact in controlled and real-life settings.

Methods: A communication campaign was co-designed with children and adolescents, grounded in the COM-B model to promote FOPWL use and healthy food choices. A randomized experiment with 1,028 parent-child dyads (ages 5–17) compared three groups: 1) Control (no labels or campaign), 2) FOPWL (warning labels only), and 3) FOPWL+C (warning labels plus communication strategy). Outcomes included the percentage of products with warning labels, number of labels per product, overall nutritional quality, and understanding of labels. Real-life impact was evaluated in 2022 using data from a national sample of 4,153 adults and 1,603 youth. Logistic regression models assessed associations between campaign awareness and healthy behaviors.

Results: The resulting “*Héroes por la Salud*” (Heroes for Health) campaign was adopted by UNICEF Mexico and later expanded by the Ministry of Health, which added materials and the jingle “Natural food is pure life: eat like us and get healthy.” Launched nationally in 2022, the campaign used multiple media channels, including social media, television, radio, SMS, and printed materials. In the online shopping simulation, participants in the FOPWL+C group

SYMPOSIUM

selected 3.4% fewer products with warning labels, 0.2 fewer labels per product, and healthier options overall (all $p < 0.05$). Real-life evaluations showed that adults and youth aware of the campaign reported greater engagement in healthy behaviors related to label use and food choices.

Conclusion: The co-designed communication campaign with children and adolescents produced culturally relevant messages that strengthened Mexico's FOPWL policy. The "Héroes por la Salud" campaign improved understanding and use of the labels, promoted healthier selections, and was associated with real-life behavior change, underscoring the value of youth-centered, theory-informed communication strategies for public health impact.

S.2.26-3

Child-centered Participatory Policy Development for Healthy Habits in School Settings: The Reactiva Tu Escuela Experience in Chile

N. Aguilar-Farias^{1,2}, C. Mella-Garcia^{1,2}, S. Miranda-Marquez^{1,2}

¹Universidad de La Frontera, Department of Physical Education, Sports and Recreation, Temuco, Chile, ²UFRO Activate Research Group, Department of Physical Education, Sports and Recreation, Temuco, Chile

S.2.26 Participatory Research in Health Promotion: Participatory research with children and stakeholders: challenges and lessons for promoting healthy eating in Latin America

Room 3, May 29, 2026, 8:00 AM - 9:00 AM

Purpose: The Reactiva Tu Escuela project aimed to improve children and adolescents' wellbeing in Temuco, Chile, by promoting healthy eating and physical activity habits through a child-centered participatory approach. This study focuses on the project's specific objectives: to develop relevant and scalable public policy recommendations at local and national levels through participatory processes that centered children's voices in policy dialogue.

Methods: Reactiva tu escuela was implemented in 2023 across six schools. The project established representative committees in each institution, including children, adolescents, families, educators, and administrators. Participatory methodologies (photovoice, world café, flowcharts, and reflective analysis) enabled collaborative situational diagnoses and action plan development. Children's perspectives, needs, and solutions informed the design and implementation of contextualized interventions. The final stage included two technical-community working tables that brought together 72 participants, including 19 students and 53 adults, alongside institutional representatives and civil society organizations to elaborate policy recommendations through structured dialogue processes that validated children's voices as central to decision-making.

Results: The participatory process successfully elevated children's voices in policy dialogue, generating differentiated recommendations at local and national scales. Local policy recommendations emphasized: optimizing physical spaces in schools and communities; increasing and diversifying school programming; strengthening educational community capacities in healthy habits promotion and socioemotional education; and improving quality and handling of school meals. National policy recommendations focused on: strengthening intersectoral coordination of initiatives and budgets; promoting family involvement strategies in school activities; improving school food environments; and evaluating time distribution between academic activities and children's integral development with a non-competitive approach. Working tables effectively translated grassroots experiences and children's perspectives into actionable policy proposals spanning multiple governance levels.

Conclusion: Child-centered participatory methodologies successfully positioned children as legitimate stakeholders in policy development, demonstrating that meaningful youth participation generates relevant, contextually appropriate, and scalable recommendations. This approach challenges traditional top-down policy formulation by validating children's lived experiences as essential evidence for decision-making. The technical-community working tables bridged educational communities and policymakers, enabling children's voices to inform local and national policy agendas. This model offers a replicable framework for participatory policy formulation in educational health promotion contexts.

S.2.27-1

A Virtual Intervention Trial with Video Feedback Coaching to Support Healthy Growth and Responsive Feeding: The Mother's and Caregivers Investing in Children (MAGIC)-FEED Program

E. Widen¹, M. Arredondo², N. Perry², S. Foster¹, L. Hernandez¹, N. Hazen², M. Abrego¹, R. Macasieb², L. Sandoval Mejia¹, I. Martinez¹, S. Dube¹, A. Ramos-Gonzalez¹, K. Whitley¹, A. Callum², M. Gray³, M. Gallas³, M. Burgermaster^{1,4}, P. Rathouz⁴, D. Powers⁵, D. Jacobvitz²

¹The University of Texas at Austin, Nutritional Sciences, Austin, United States, ²The University of Texas at Austin, Human Development and Family Sciences, Austin, United States, ³The University of Texas at Austin, Pediatrics, Austin, United States, ⁴The University of Texas at Austin, Population Health, Austin, United States, ⁵The University of Texas at Austin, Sociology, Austin, United States

S.2.27 Childrend and families: Feeding the future: novel trial design approaches to advance nutrition during postpartum period and beyond

Room 4, May 29, 2026, 8:00 AM - 9:00 AM

Purpose: Most behavioral interventions to prevent early childhood obesity have demonstrated limited effects, and new approaches are needed. We designed and implemented a virtual intervention incorporating video feedback coaching that aimed to foster responsive feeding and caregiving with the goal of supporting healthy growth, dietary quality, and responsive feeding practices.

Methods: The Mothers and other careGivers Investing in Children (MAGIC) 1.0 study (NCT04177472) randomized 135 families with infants in Central Texas USA to a virtual complementary feeding intervention with video feedback coaching on responsive feeding (MAGIC-FEED) or an attention control arm focused on infant safety (MAGIC-SAFE) in English or Spanish led by trained staff. Coaching combined immediate and delayed feedback using video clips from prior feeding sessions to reinforce responsive behavior. Visits included baseline (4-5 months), intervention (6, 7, 8, and 10 months), and outcomes (13-months). Modified food frequency questionnaires were used to assess dietary intake and quality, and feeding videos were assessed and objectively coded across infancy for infant and caregiver responsive feeding behaviors with Chatoor Feeding and Hazen Sensitivity scales. At 13 months, anthropometry was measured and WHO z-scores were calculated. Intervention arm differences were evaluated through bivariate analyses and covariate adjusted linear regression models.

Results: MAGIC-FEED implementation was refined during piloting. For example, responsive feeding feedback originally planned to be in the moment was shifted to be delayed due to infant distraction. Of the 135 randomized families, 112 were measured at 13-months. In adjusted models, FEED was associated with 0.47 units lower weight-for-age Z-scores at 13-months (95% CI: -0.87, -0.08), compared to SAFE, but not BMI Z-scores or infant dietary quality. Among families with coded videos, FEED was associated with higher scores for caregiver sensitivity and reciprocity at 10 months and lower scores for conflict and missing cues.

Conclusion: MAGIC-FEED, a virtual complementary feeding intervention with video-feedback coaching, is associated with lower infant weight at 13-months and improved responsive feeding behaviors. These results highlight a novel, accessible approach for supporting healthy growth in young children. Further research is needed to evaluate program effectiveness across populations, and to understand longer-term impact on childhood development, growth, and obesity risk.

S.2.27 Childrend and families: Feeding the future: novel trial design approaches to advance nutrition during postpartum period and beyond

Room 4, May 29, 2026, 8:00 AM - 9:00 AM

SYMPOSIUM

Purpose:

During the postpartum period, many parents are motivated to adopt a healthful diet while simultaneously facing the barriers of this major life transition. Some make dietary swaps that they perceive to be healthier and easier, such as substituting plant-based analogues for meat; but how these changes might contribute to maternal and infant health is unknown. Controlled feeding trials are needed to provide causal evidence of how dietary changes contribute to health, particularly in the context of breastfeeding. Our objective was to evaluate if swapping beef for its ultra-processed plant-based analogue in otherwise identical meals affects breastmilk fatty acid composition in a 24-day controlled feeding trial beginning at 6-12 weeks postpartum.

Methods:

We conducted a double-blind randomized crossover feeding trial (n=23) with two 6-day diet phases during which all food was provided, separated by a 6-day washout period. Meals were prepared in a metabolic kitchen, and each meal contained 4 oz of beef or plant-based analogue, depending on the diet condition. Participants collected 3 post-feed breastmilk samples daily. Participants received ongoing support via phone and text. We analyzed beef, plant-based substitute, and breastmilk samples collected on day 6 of each condition for 27 fatty acids using standard biochemical procedures. T-tests compared fatty acids in intervention foods and breastmilk samples, maternal weight, palatability and satiety ratings.

Results:

17 participants completed the trial per protocol, with over 95% dietary compliance and at least 1ml breastmilk at each sample timepoint. While maternal weight, palatability, and satiety did not differ between conditions, we observed differences in 13 breastmilk fatty acids (e.g., a 15% reduction in arachidonic acid during the analogue diet, $p < .001$), directly mirroring the experimental foods.

Conclusion:

Controlled feeding trials during the postpartum period enable objective assessment of how dietary changes affect postpartum biomarkers. Our intensive trial protocol with multiple touch points resulted in high quality data and provided the first evidence that swapping just one food item results in rapid breastmilk changes without affecting maternal weight or satiety. Differences in breastmilk composition have implications for infant development, highlighting the need to consider the dynamic role of maternal diet in breastmilk composition in postpartum dietary guidance.

S.2.27-3

Using an Innovative Fusion Design to Test the Effects of a Novel Healthy Corner Store Model to Improve Postpartum Food and Nutrition Security and Weight

S. Hinkle^{1,2}, K. Glazer^{2,1}, C. Durnwald², S. Hua³

¹University of Pennsylvania Perelman School of Medicine, Department of Biostatistics, Epidemiology and Informatics, Philadelphia, United States, ²University of Pennsylvania Perelman School of Medicine, Department of Obstetrics and Gynecology, Philadelphia, United States, ³University of Pennsylvania Perelman School of Medicine, Department of Medical Ethics and Health Policy, Philadelphia, United States

S.2.27 Children and families: Feeding the future: novel trial design approaches to advance nutrition during postpartum period and beyond

Room 4, May 29, 2026, 8:00 AM - 9:00 AM

Purpose: Over one in four single-mother United States households experience food insecurity. While government benefits provide essential financial support, they cannot overcome barriers such as lack of time to cook, inadequate cooking skills, or insufficient equipment. Current policies prohibit using benefits for hot, prepared meals—perpetuating barriers. The Community Grocer (TCG), a new community-run corner store in a low-food access neighborhood (Philadelphia, Pennsylvania) offers a novel solution: nutritious meal kits that can be purchased with benefits and taken home or exchanged at no cost for hot meals at a neighboring community-run kitchen. Our objective is to investigate whether this model improves postpartum food and nutrition security and health.

Methods: The NOURISH Postpartum Study employs a novel fusion design combining a randomized controlled trial (RCT) with a non-randomized cohort. We are enrolling food-insecure pregnant individuals and following them through 24 weeks postpartum. RCT participants (n=125) are randomized (2:2:1) to: 1) weekly \$40 TCG grocery credits for 12 weeks postpartum (n=50); 2) weekly \$40 unconditional cash transfer for 12 weeks (n=50); or 3) usual postpartum care (n=25). The RCT addresses a key limitation: we cannot randomize where people shop, rather, we incentivize behavior change through grocery credits. Given high RCT costs, it is paired with an augmentation cohort (n=125)

that completes identical measures without randomization to enhance generalizability and increase power. Primary exposure is shopping at TCG (n=250); secondary exposure is the RCT arm, distinguishing grocery credits versus cash alone (n=125). Primary outcomes are household food and nutrition security and postpartum weight.

Results: Our community needs assessment (n=184) identified obstacles to healthy eating: lack of time to cook (49.6%), cooking skills (21.9%), and stove/oven (10.6%), refrigerator (14.3%), or utensils (10.0%). Experiencing multiple barriers was associated with food (aRR=2.51; 95% CI: 1.14-5.55) and nutrition (aRR=2.09; 1.10-4.00) insecurity. The NOURISH study is ongoing; we will discuss this innovative strategy for implementing and studying behavior change, the application of this novel fusion design and how to analyze the data, and challenges and successes in participant enrollment in a fusion study.

Conclusion: This study tests whether reducing structural barriers to healthy eating improves postpartum food and nutrition security and health.

S.2.28-1

Lessons Learned from the Implementation of the SI! Program over the World: A 15-year Global Review of Health Promotion in Children and Adolescents

G. Santos-Beneit^{1,2}, A. de Cos-Gandoy^{1,2}, P. Bodega^{1,2}, C. Rodríguez¹, X. Orrit¹, M. de Miguel^{1,2}, D. Haro¹, J. Martínez-Gómez², J.M. Fernández-Alvira², C. Peyra^{1,3}, I. Carvajal¹, R. Fernandez-Jimenez^{2,4,5}, V. Fuster^{1,2,3}

¹SHE Foundation, Barcelona, Spain, ²Centro Nacional de Investigaciones Cardiovasculares (CNIC), Madrid, Spain, ³Mount Sinai Fuster Heart Hospital, New York, United States, ⁴Hospital Universitario Clínico San Carlos, IdISSC, Madrid, Spain, ⁵Centro de Investigación Biomédica En Red En Enfermedades Cardiovasculares (CIBERCV), Madrid, Spain

S.2.28 Motivation and behavior change: Fifteen Years of the SI! Program: Lessons, Innovations, and Global Impact of a School-Based Health Promotion Intervention

Room 5, May 29, 2026, 8:00 AM - 9:00 AM

Purpose: Over the past 15 years, our research has focused on identifying and refining strategies to optimize a school-based intervention that promotes lifelong healthy habits from early childhood through adolescence. The SI! Program (Salud Integral) is a comprehensive, multicomponent, and multilevel educational initiative addressing diet, physical activity, emotional well-being, and knowledge of the human body and heart. This work summarizes findings from a long-term, multi-country research effort evaluating the implementation, effectiveness, and sustainability of the SI! Program across diverse cultural and socioeconomic contexts.

Methods: Over its 15-year trajectory, the SI! Program has been implemented in more than 235 educational institutions, engaging over 37,000 students aged 3 to 16 years and providing formal training to more than 2,250 teachers to ensure effective program delivery. The program has been evaluated through randomized controlled trials conducted in Colombia, Spain, and the United States, encompassing Preschool, Elementary, and Secondary education levels. Standardized instruments assessed knowledge, attitudes, behaviors, and psychosocial factors, as well as physical parameters including body mass index, skinfold thickness, waist circumference, blood pressure, glucose, and cholesterol. Contextual factors such as socioeconomic background and exposure to the intervention were analyzed to determine their influence on program outcomes and sustainability.

Results: Across all sites and age groups, the SI! Program demonstrated significant improvements in children's health knowledge, attitudes, and behaviors, although the magnitude of effects varied by developmental stage and context. Adherence to the curriculum and institutional commitment were identified as key determinants of success. Socioeconomic background influenced both baseline health indicators and responsiveness to the intervention. Findings also revealed that benefits declined over time without periodic reintervention and that active involvement of teachers, families, and the broader school community enhanced engagement for a long-term impact.

Conclusion: The SI! Program provides strong evidence that structured, school-based, and community-supported interventions can effectively foster cardiovascular health from early childhood through adolescence. Long-term sustainability requires reintervention strategies, contextual adaptation, and active participation of families and educators. Scaling such initiatives globally could meaningfully contribute to reducing the future burden of cardiovascular disease by establishing healthy lifestyles early in life.

The New SI! Program Model: Implementation and Evaluation of an Integrating Collective Action and Socio-emotional Learning

M. de Miguel^{1,2}, C. Rodríguez¹, X. Órrit¹, P. Bodega^{1,2}, A. de Cos-Gandoy^{1,2}, M. Beneito-Durá¹, D. Haro¹, C. Peyra^{1,3}, I. Carvajal¹, J. Martínez-Gómez², J.M. Fernández-Alvira², F. Van Nassau⁴, R. Fernández-Jiménez^{2,5,6}, G. Santos-Beneit^{1,2}, V. Fuster^{1,2,3}

¹Foundation for Science, Health and Education (SHE), Barcelona, Spain, ²Centro Nacional de Investigaciones Cardiovasculares (CNIC), Madrid, Spain, ³Mount Sinai Fuster Heart Hospital, New York, United States, ⁴Department of Public and Occupational Health and Amsterdam Public Health Research Institute, Amsterdam, Netherlands, ⁵Hospital Universitario Clínico San Carlos, IdISSC, Madrid, Spain, ⁶Centro de Investigación Biomédica en Red en Enfermedades Cardiovasculares (CIBERCV), Madrid, Spain

S.2.28 Motivation and behavior change: Fifteen Years of the SI! Program: Lessons, Innovations, and Global Impact of a School-Based Health Promotion Intervention

Room 5, May 29, 2026, 8:00 AM - 9:00 AM

Purpose: The revised SI! Program builds upon insights from earlier trials to enhance adherence and promote long-term healthy behaviors in children. This updated model integrates a reintervention on socio-emotional learning (SEL) with collective action, engaging the school community and families to promote lasting healthy habits. We are conducting a 6-year process evaluation to analyze the association between implementation quality and program effectiveness within a cluster-randomized controlled trial comparing a reintervention group and a single-intervention group.

Methods: The trial enrolled 977 children (mean age 6.2 years, 51.6% girls) from 50 schools in Madrid and Barcelona, Spain. The revised program retains the original components (healthy diet, physical activity, body and heart awareness, and emotional management) while introducing a strengthened implementation strategy. This includes 16 SEL classroom sessions and a comprehensive school environment component designed to promote self-assessment, planning, and collective improvement. Schools received a welcome pack with educational materials, access to an interactive Healthmeter tool for monitoring health-promoting routines, and guidance for organizing an annual Healthy Day event. The research team provided formal training for teachers and staff and ongoing support throughout the implementation process. Data collection included implementation questionnaires (n=61), satisfaction questionnaires (n=80) and Healthmeter usage statistics.

Results: Implementation has begun in 18 schools in Madrid, involving over 10,000 students and more than 800 teachers. During the first year, 119 teachers were trained, with an average satisfaction score of 8.5 (scale 0–10). Schools implemented a mean of 12 SEL sessions in the first year. Use of school environment resources ranged from 11% (fatigue tracking logs) to 89% (posters and infographics). Only five schools (22%) used the Healthmeter, and half of the schools organized a Healthy Day (22% involved families). Teachers' satisfaction with the research team averaged 8.7 (1.5), and satisfaction with educational resources ranged from 6.8 (2.1) (Healthmeter) to 9.6 (0.6) (welcome pack).

Conclusion: Findings from the first year of implementation demonstrate high satisfaction and strong adherence to program components. As implementation continues, complete process evaluation data will enable analysis of the association between implementation quality and program effectiveness, contributing to evidence on sustainable health promotion in school settings and providing insights.

S.2.28 Motivation and behavior change: Fifteen Years of the SII Program: Lessons, Innovations, and Global Impact of a School-Based Health Promotion Intervention

Room 5, May 29, 2026, 8:00 AM - 9:00 AM

Purpose: There are several scientific challenges to measuring the efficacy of a school-based intervention. One of the main challenges, particularly for research on children and adolescents, is the nature of the assessment tools. The American Heart Association developed the Life's Essential 8 (LE-8) score to assess cardiovascular health (CVH). However, blood-related metrics remain stable especially in young people and short-term studies, which can attenuate or mask the observed effect of lifestyle changes on overall CVH. Drawing on evidence from earlier trials, we present the SII-Child score, a straightforward and reliable measure of lifestyle-related CVH in children and adolescents.

Methods: The SII-Child score adapts the individual lifestyle-related metrics of the LE-8 score, covering diet, physical activity, nicotine exposure, sleep health, and body mass index. Differences in 4-year changes of the overall LE-8 and the SII-Child scores in the participants from the SII Program for Secondary Schools trial in Spain were assessed. Bland Altman plots were used to measure the agreement between the LE-8 score and the overall and individual metrics of the SII-Child score.

Results: In total, 796, 760, and 683 participants were included in the analysis at baseline (≈ 12 years of age), 2-year follow-up (≈ 14 years), and 4-year follow-up (≈ 16 years), respectively. Mean LE-8 and SII-Child scores (range 0-100 points) at baseline were 77.5 ± 8.0 and 74.8 ± 8.9 , respectively. The change in the SII-Child was significantly greater than in the LE-8 at 2-year (between-score change difference, -2.45 [95%CI: -3.00 ; -1.90]) and 4-year follow-up (-5.19 points [95%CI: -5.80 ; -4.58]). The SII-Child classified fewer adolescents in ideal CVH and more in poor CVH, and both scores classified most adolescents in intermediate CVH. The SII-Child showed good agreement with the overall and the individual lifestyle-related metrics of the LE-8.

Conclusion: The SII-Child is a simple and reliable tool for the assessment of lifestyle-related CVH changes. Blood parameters usually remain within the ideal range during childhood and adolescence, potentially masking changes in overall CVH. Lifestyle-related CVH scores may better discriminate changes in lifestyle and consequently may be more suitable for monitoring CVH in the context of surveillance studies and health promotion interventions in children and adolescents.

S.2.29-1

Physical Activity and Health-related Physical Fitness among Children and Adolescents and the United Nations Sustainable Development Goals

D.A.S. Silva¹, E. Lee^{2,3}, M. Tremblay⁴

¹Federal University of Santa Catarina, Physical Education, Florianópolis, Brazil, ²Yonsei University, Department of Sport Industry, Seoul, Korea, Republic of, ³Queen's University, School of Kinesiology and Health Studies, Kingston, Canada,

⁴Children's Hospital of Eastern Ontario Research Institute, Healthy Active Living and Obesity Research Group, Ottawa, Canada

S.2.29 Systems Science: Physical activity as a catalyst for planetary health and global health equity

Room 6, May 29, 2026, 8:00 AM - 9:00 AM

Purpose: Physical activity (PA) and health-related physical fitness (HRPF) underpin child and adolescent health and equitable, resilient societies. Beyond direct health gains, PA supports safer, greener communities, while fitness both reflects these environments and predicts future health and participation. These pathways align with Sustainable Development Goals (SDGs), notably Good Health and Well-Being (SDG 3), Gender Equality (SDG 5), Industry, Innovation and Infrastructure (SDG 9), Sustainable Cities and Communities (SDG 11), Climate Action (SDG 13), Life on Land (SDG 15), and Peace, Justice, and Strong Institutions (SDG 16). We examined country-level associations between SDG performance and youth indicators of PA and HRPF.

Methods: This was a country-level ecological study. We analyzed PA indicators for 57 countries/jurisdictions from Global Matrix 4.0 and HRPF components for 17 countries in the WHO European Region. SDG metrics came from the SDG Transformation Center (country-specific scores across all 17 Goals). We focused on SDGs 3, 5, 9, 11, 13, 15, and 16. Associations between SDG scores and PA indicators and HRPF components were tested using Spearman's rank correlation.

SYMPOSIUM

Results: Countries/jurisdictions with high or moderate performance on SDGs 3, 9, 11, and 16 achieved higher grades in key PA indicators, specifically Organized Sport and PA, Community and Environment, and Government Investments and Strategies. In contrast, those performing well on SDG 13 (Climate Action) tended to have lower grades on these indicators. For HRPf, strength, coordination, and speed showed positive associations with SDGs 3, 5, 9, 11, and 16, whereas inverse associations were observed with SDG 13.

Conclusion: National progress on health, gender equity, infrastructure, urban planning, and institutions aligns with more favorable PA systems and youth fitness profiles, whereas higher performance on climate action was inversely related to these indicators. These patterns highlight the need to integrate PA promotion and explicit HRPf targets into SDG implementation and monitoring.

S.2.29-2

Physical Activity as a Key to Advancing Planetary Health: A Synthesis of Evidence from Two Systematic Reviews

E.-Y. Lee^{1,2}, D.A.S. Silva³, M.S. Tremblay⁴

¹Yonsei University, Seoul, Korea, Republic of, ²Queen's University, Kingston, Canada, ³Federal University of Santa Catarina, Florianópolis, Brazil, ⁴Children's Hospital of Eastern Ontario Research Institute, Ottawa, Canada

S.2.29 Systems Science: Physical activity as a catalyst for planetary health and global health equity

Room 6, May 29, 2026, 8:00 AM - 9:00 AM

Purpose: As the climate crisis increasingly shapes global health and well-being, physical activity (PA) emerges as both a protective behavior and a potential pathway for advancing planetary health. This paper synthesizes findings from two systematic reviews examining:

- (1) the interrelationships between climate change indicators, PA, and health; and
 - (2) the associations between ambient environmental conditions and active outdoor play across the lifespan.
- Intended for policymakers, public health practitioners, and researchers, this presentation highlights PA promotion as a promising and under-utilized strategy to build healthy, resilient individuals and communities amid environmental shifts.

Methods: This presentation draws evidence from two recently published systematic reviews. In the first review, eligible studies examined linkages between indicators of climate change, PA, and health outcomes. The second review was based on studies assessing associations between meteorological, atmospheric, and/or land-use factors and active outdoor play. Narrative synthesis and meta-synthesis approaches were applied to characterize associations, directionality, and evidence strength.

Results: Across both reviews, 123 studies encompassing over 6.7 million participants were analyzed. In the first review (n=79 studies), 34.7% of studies supported PA as a mediator, where adverse climate indicators were associated with lower PA and, in turn, associated with worse health outcomes. PA also favorably modified the negative association between climate change and health in 28% of studies, highlighting its potential buffering role. The second review (n=44 studies) found that ambient environmental conditions shape active outdoor play. Specifically, while meteorological factors often showed null associations, unfavorable associations were observed for atmospheric and land-use conditions, particularly in urbanized or polluted settings. This review also found adaptive strategies individuals and communities employ to maintain active outdoor play with emerging climate challenges and the role of active outdoor play in fostering resilience, potentially contributing to SDGs.

Conclusion: These reviews provide converging evidence that PA and active outdoor play are integral to building health and climate resilience. However, most studies were from high-income countries, and the evidence base remains limited, particularly for vulnerable populations. Strengthening empirical research and integrating PA promotion within climate adaptation, mitigation, and resilience policies are essential next steps to advance healthy movement behaviours, planetary health and global health equity.

S.2.30-1

Decreasing Sweetened Beverages and Increasing Tap Water Consumption among Primary School Children Aged 8-10 Years: Contextual Insights from the DRINK Trial (Belgium, 2021-2023)

L. Desbouys¹, W. Assakali¹, I. Thiébaud², M. Rouche¹, K. Castetbon¹

S.2.30 Motivation and behavior change: From implementation to analysis: methodological insights and results from school-based interventions to improve beverage consumption (DRINK Trial, Belgium, 2021-2023)

Room 7, May 29, 2026, 8:00 AM - 9:00 AM

Purpose: The DRINK trial, initiated in 2021 across 46 French-speaking schools in Belgium, was developed to evaluate interventions aimed at reducing sweetened beverages (SB) and increasing tap water consumption among 8-to-10-year-old children. Its conclusions must be interpreted considering the post-pandemic context and the specific population in which it was implemented.

Methods: Baseline data were obtained from children, their parents, and school staff in schools previously selected through a stratified random sampling. Children completed a self-administered questionnaire covering living conditions, beverage-related behaviours, and health-related aspects. They also completed a 4-day booklet adapted to their age, from which usual intake was derived (SPADE method). Parents supplied complementary information regarding components considered too complex for children in this age group. Lastly, dietitians interviewed school staff to document health promotion activities related to nutrition and sustainability implemented within schools. Descriptive analyses were carried out using the maximum number of observations available for each surveyed population.

Results: The theoretical number of children across the 46 participating schools was 4,437, of whom 3,128 completed their questionnaire, and 2,747 provided a valid 4-day booklet. Moreover, 2,680 questionnaires were available from their parents. Participation rate was lower than expected in schools with low socioeconomic status and in the Brussels region. The population was predominantly composed of girls, born in Belgium, living in moderately affluent families, with siblings, and two working parents. Usual intake of total beverages was 1,109 ml/day (95% CI: 1,092-1,132), including 677 ml/day of water (660-699), 345 ml/day of SB (331-359), and 60 ml/day of milk (56-64). Most schools provided recommendations for healthy snacks (n= 41 over 46), including guidance on soft drinks (n= 33), water (n= 26), and fruit juices (n= 17). Nearly all schools offered access to plain water (n= 44) and implemented a waste reduction or recycling initiatives (n= 41). However, even fewer than half of the schools facilitated and encouraged water consumption specifically.

Conclusion: The DRINK trial provides valuable insights into the implementation of school-based interventions aimed at improving dietary behaviours among children. The available data will help assess the intervention's efficiency, considering key sustainability factors.

S.2.30-2

Methodological Challenges in Cluster-randomized Trials Regarding Dietary Behaviour: Insights from the DRINK Trial (Belgium, 2021-2023)

M. Rouche¹, L. Desbouys¹, W. Assakali¹, I. Thiébaud², K. Castetbon¹

¹Université libre de Bruxelles, Research Center in Epidemiology, Biostatistics and Clinical Research, School of Public Health, Brussels, Belgium, ²Club Européen des Diététiciens de l'Enfance (CEDE), Ath, Belgium

S.2.30 Motivation and behavior change: From implementation to analysis: methodological insights and results from school-based interventions to improve beverage consumption (DRINK Trial, Belgium, 2021-2023)

Room 7, May 29, 2026, 8:00 AM - 9:00 AM

Purpose: Although cluster-randomised trials provide high levels of evidence, they remain subject to methodological challenges such as high attrition rates and group imbalance. In nutrition research, additional analytical challenges arise, including appropriate data collection and estimates of usual dietary intake. For the first time, these critical points are jointly addressed to robustly assess intervention effects on usual sweetened beverage (SB) intakes two

SYMPOSIUM

years after implementation of the DRINK trial.

Methods: In 2021, forty-six primary schools were randomized into: (i) control; (ii) nutrition-based intervention; (iii) sustainability-based intervention; and (iv) both interventions. Children completed 4-day diaries. Estimating SB intakes presented several challenges: consumption was episodic and exhibit high within-person variability. The cluster design, including missing information at the individual level after the follow-up period, required the selection of an appropriate statistical approach.

Results: The National Cancer Institute (NCI) method is used to estimate the usual consumption, accounting properly for the within-individual variability and zero-inflated distributions. The primary outcome is defined as the relative change in usual beverage consumption between baseline and two-year follow-up. Following some adaptations of the NCI method, simulated usual beverage intake values is generated at baseline and at two-year follow-up within intervention group and for each participant, using identical between-person deviates. Relative changes in usual intake are computed for each simulated individual and combined using Rubin's rule to derive a single estimate of change per participant. Further, a two-stage Targeted Minimum Loss-Based Estimation (2S-TMLE) framework, combining machine-learning flexibility with statistical efficiency, is implemented. First, missing outcomes are modelled within each cluster (schools), with age included as a predictor of missingness. Second, relative changes in BS consumption are estimated at the cluster level. This approach leverages information from 1,643 participants with missing outcome after intervention to refine predictions from 445 participants with complete data. Sensitivity analyses further incorporate consumption at one-year follow-up as an additional missingness predictor.

Conclusion: By combining the NCI and 2S-TMLE methods, this innovative work illustrates how recent advances in modelling can strengthen the evaluation of complex nutrition trial. This approach enhances precision, reduces attrition-related bias, and supports valid estimation of changes in usual intake.

S.2.30-3

Decreasing Consumption of Sweetened Beverages among 8-to-10-year-old Children in Primary Schools: Main Results of the DRINK Trial (Belgium, 2021-2023)

K. Castetbon¹, L. Desbouys¹, W. Assakali¹, I. Thiébaud², M. Rouche¹

¹Université Libre de Bruxelles, School of Public Health, Brussels, Belgium, ²Club Européen des Diététiciens de l'Enfance (CEDE), Ath, Belgium

S.2.30 Motivation and behavior change: From implementation to analysis: methodological insights and results from school-based interventions to improve beverage consumption (DRINK Trial, Belgium, 2021-2023)

Room 7, May 29, 2026, 8:00 AM - 9:00 AM

Purpose: The DRINK trial was developed to evaluate interventions aimed at decreasing sweetened beverages (SB) (principal criterion) and increasing tap water consumption (secondary criterion) in French-speaking primary schools in Belgium. One of its novelties lies in testing nutrition-based and environmental sustainability-based interventions using a factorial plan for school randomisation.

Methods: Baseline data were collected in 2021 from children, parents and school staff in 46 primary schools. Recruitment procedures were adapted due to the ongoing impact of Covid-19 on school organization, and 22 of the 46 schools were eventually included in autumn 2021. Then, schools were randomized into four groups: (i) control; (ii) nutrition-based intervention; (iii) sustainability-based intervention; and (iv) both interventions. Carried out from early 2022 to July 2023, interventions included scheduled water breaks and provision of posters, leaflets, reusable cups and bottles. In 2021, 2022 and 2023, a 4-day diary adapted to the participants' age was provided, from which usual beverage intake was derived for each wave (NCI method). The main analyses are underway under blinded allocation of schools into groups, a condition that will be lifted before spring 2026. Given the cluster randomisation design and the presence of missing data from children in the participating schools, the two-stage targeted minimum loss estimation (2S-TMLE) method is selected. Imbalance in baseline characteristics between intervention groups will be accounted for in the final model.

Results: Among the 46 schools initially included (n=3,664 children), 13 withdrew before the final wave of data collection (n= 1,155 children). Due to missing information either from protocol adaptation (notably, 1,760 children without data in 2023) or invalid records (e.g., 135 children with invalid 4-day booklets or 105 classified as over-reporters), the main analyses will be based on 445 children from 26 schools. However, the 2S-TMLE method will allow incorporating observations from 1,643 children from the same 26 schools to improve estimates of the intervention effect on usual SB intake.

Conclusion: The DRINK trial combined school-based interventions designed to ensure feasibility with a sophisticated analytical strategy. Its primary findings on changes in SB usual intake will be complemented with analyses of secondary objectives and stratified analysis.

S.2.31-1

The pathways between climate change, food and water insecurity, diet quality, and disease risk: a review

J. Webster¹, J. Crowther², S. Young³, G. Leslie⁴

¹University of Technology Sydney, World Health Organisation Collaborating Centre on Nursing, Midwifery and Health Development, Sydney, Australia, ²The George Institute for Global Health, Food Policy Division, Sydney, Australia, ³Northwestern University, NU Water, Chicago, Australia, ⁴University of New South Wales, Global Water Institute, Sydney, Australia

S.2.31 Policies and environments: Policies for planetary diets: the nexus of climate change, nutrition, and health
Room 8, May 29, 2026, 8:00 AM - 9:00 AM

Purpose: Food and water security are foundational to good nutrition and increasingly threatened by climate change. Half of the world's food-insecure population resides in the Asia Pacific region, where rising temperatures, erratic rainfall, and extreme weather events compound vulnerabilities driven by gender inequities and fragmented systems. This abstract presents outcomes from the inaugural FoodWISE Asia Pacific workshop (17–19 September, Sydney), which aimed to catalyse action on improving food environments by integrating experiential tools that capture lived experiences of food and water insecurity to inform policy and practice.

Methods: The workshop convened 50 participants from 14 countries, including researchers, policymakers, Indigenous leaders, and community advocates. Experiential tools such as the Water Insecurity Experiences Scales (WISE) and Household Food Insecurity Access Scale (HFIAS) were showcased to demonstrate their utility in generating policy-relevant, gender-sensitive, and community-driven data, and using this evidence to inform action and drive policy change.

Results: Participants affirmed the urgent need for integrated, community-led approaches to address food and water insecurity. The workshop culminated in the co-creation of the FoodWISE Asia Pacific Network and a draft manifesto to guide collective action. Key themes included:

- Addressing food and water insecurity concurrently
- Elevating Indigenous knowledge
- Harnessing lived experience data
- Strengthening cross-sector collaboration

Four seed grant initiatives were funded to scale community-led solutions across Southeast Asia, Timor-Leste, Australia, and the Pacific. A joint review paper on experiential measures was initiated, and a regional platform to support ongoing collaboration was launched.

Conclusion: Improving food environments to ensure food and water security is essential for advancing nutrition and health equity—particularly in the context of climate-related shocks. The FoodWISE Asia Pacific Network offers a timely and inclusive platform to embed experiential tools into policy and practice. By centring lived experiences and Indigenous knowledge and fostering regional collaboration, this initiative aims to drive transformative, climate-resilient solutions that promote sustainable and equitable food systems.

S.2.31-2

Evaluating the Effects of Different Climate Impact Menu Labels on Meal Selections in Two Fast Food Restaurants: An Online Randomized Controlled Trial

J. Wolfson¹, A.C. Tucker¹, A. Musicus², B. Kim³, D. Barquera¹, E. Choi¹, N. Carr¹, A. Reimold⁴, R. Santo⁵, C. Cho⁵, C. Leung², C. Roberto⁶, J. Falbe⁴

¹Johns Hopkins University, International Health, Baltimore, United States, ²Harvard T.H. Chan School of Public Health, Nutrition, Boston, United States, ³Johns Hopkins University, Center for a Livable Future, Baltimore, United States, ⁴University of California Davis, Human Ecology, Davis, United States, ⁵World Resources Institute, Washington, DC, United States, ⁶University of Pennsylvania, Medical Ethics and Health Policy, Philadelphia, United States

SYMPOSIUM

S.2.31 Policies and environments: Policies for planetary diets: the nexus of climate change, nutrition, and health Room 8, May 29, 2026, 8:00 AM - 9:00 AM

Purpose: Promoting a healthy, sustainable diet is an urgent priority due to the dual threats of diet-related chronic diseases and climate change. Evidence suggests that climate-focused menu labels may promote healthy and sustainable food choices, but how label effects differ by restaurant type is unknown.

Methods: We conducted an online randomized controlled trial (N=6,294) in a nationally representative sample of United States (US) adults, recruited via the AmeriSpeak survey panel in April 2025, to test the effects of different climate menu label designs on hypothetical meal selections in two fast food restaurants: one focused on burgers and one on sandwiches. Participants were randomized to view and order from menus displaying one of five label conditions: 1) control (QR code), 2) low impact label on sustainable items, 3) high impact label on unsustainable items, 4) traffic light label (TLL), and 5) grade (A-F) label. The primary outcome was healthfulness of the meal (modified Nutrient Profile Index [NPI] score). Secondary outcomes included greenhouse gas emissions (GHGE), calories, macronutrients, and total cost of selected meals; selection of a sustainable main item; label noticeability; and the perceived message effectiveness (PME) of the labels.

Results: Compared to the control, the TLL led to significantly healthier meal selections from the burger but not the sandwich restaurant. The TLL promoted the most sustainable (lower GHGE) meal selections in both restaurants and led to the highest likelihood of selecting a sustainable main item in both restaurants. Across all conditions, participants viewing the TLL were most likely to report noticing the label and reported the highest PME. There were no differences in the cost of the selected meals across label conditions. Calories and macronutrients of selected meals did not differ across label condition in the burger restaurant, and there were few differences in the sandwich restaurant.

Conclusion: A traffic light style climate impact menu label shows the most promise for promoting healthier and more sustainable food choices in two different fast food restaurant settings. However, effects on healthfulness of selected meals were inconsistent across restaurant type, and more research is needed to investigate climate label effects in real-world settings.

S.2.31-3

Public Procurement for Biodiversity and Equity: Changes in Sociobiodiversity Food Purchases for School Feeding in the Brazilian Amazon

A.C. Duran¹, M. Milosz², I. Pereira¹, N. Alves-Santos³

¹University of Campinas, Center for Food Studies and Research, Campinas, Brazil, ²University of Sao Paulo, Department of Economics, Sao Paulo, Brazil, ³Federal University of Pará, Department of Nutrition, Belem, Brazil

S.2.31 Policies and environments: Policies for planetary diets: the nexus of climate change, nutrition, and health Room 8, May 29, 2026, 8:00 AM - 9:00 AM

Purpose: Public food procurement plays a key role in advancing healthy, sustainable, and inclusive food systems. In Brazil, the National School Feeding Program (PNAE) mandates purchases from family farmers, including foods from sociobiodiversity—native species, traditional crops, and products from sustainable extractivism. This study fills an important gap in the literature that links food procurement to sustainability to analyze changes in the procurement of sociobiodiversity foods using national transfers for local governments to procure foods for PNAE across 772 municipalities in Brazil's Legal Amazon from 2015 to 2022.

Methods: We used the Brazilian Ministry of Agriculture definition of foods from Brazil's legal Amazon sociobiodiversity and tracked their local procurement using procurement accountability reports from the National Fund for the Development of Education (FNDE). We compared the share of these procured foods using regular bidding processes and the simplified direct procurement instrument available to family farmers.

Results: Procurement of foods from Brazil's legal Amazon sociobiodiversity increased from 3.1 to 7.6 % of the overall share of the national transfers for municipalities to procure foods to PNAE in the region between 2015 and 2022. Most of this increase was through the simplified direct procurement instrument available to family farmers, which had an increase in their share from 9.3% to 18.0%. Less than 0.1% of the share of purchases done through regular bidding was used to procure foods from Brazil's legal Amazon sociobiodiversity throughout the study period. Top procured foods included manioc, pineapple, guava, passion fruit, and cashew.

Conclusion: These results highlight public procurement's potential to strengthen sociobiodiversity markets and promote culturally sensitive and sustainable rural development.

Park Planning with Young People Using Design Thinking and Artificial Intelligence

E. Rivera¹, J. Veitch², S. Cassar¹, A. Hipp³, V. Romero⁴, S. Schoeppe⁵

¹Central Queensland University, Appleton Institute, Melbourne, Australia, ²Deakin University, Institute for Physical Activity and Nutrition, Burwood, Australia, ³North Carolina State University, Raleigh, United States, ⁴University of Melbourne, Melbourne, Australia, ⁵Central Queensland University, Appleton Institute, Rockhampton, Australia

S.2.32 Participatory Research in Health Promotion: How to apply participatory health research with emerging approaches and priority populations

Room 9, May 29, 2026, 8:00 AM - 9:00 AM

Purpose: Parks can support physical activity, socialising, and nature connection. However, parks are underutilised by young people (16-21 years), possibly due to current park planning being led by adult experts without active involvement from end-users. Conducting participatory research provides an avenue for engaging young people to problem-solve barriers to park use and develop preferred park designs.

Methods: This study developed and piloted the feasibility of an approach for designing, prototyping, and testing parks with young people, using design thinking and artificial intelligence, which have been used in landscape architecture in cities and may be beneficial to community engagement in park planning. Phase 1 involved an in-person workshop with young people (n=15), where they applied design thinking exercises. This involved empathy mapping to capture their thoughts, feelings, and emotions concerning visiting parks, and journey mapping to visualise their park use including barriers and enablers. Phase 2 entailed another in-person workshop with the same young people, where they prototyped park designs using text-to-media artificial intelligence tools. Phase 3 involved virtual focus groups with park planners (n=30) to explore their perceptions of the feasibility of this new park planning approach with young people for translation into park planning practice. Young people and park planners were recruited through social media, snowballing, and partner organisations. Qualitative content analysis was used to analyse the data (workshop transcripts, empathy maps, journey maps, park design images and videos, focus group transcripts) from all phases.

Results: This presentation will describe a novel approach for park design, prototyping, and testing with young people using design thinking and artificial intelligence and detail the methods and procedures to inform participatory research projects in related contexts. As Phases 1-2 will occur between November 2025-April 2026, preliminary findings will be shared.

Conclusion: This project will identify young people's park preferences and provide a potential new approach for actively engaging them in park planning practice. If feasible this new approach can be adapted for other population groups and settings to ensure that park planning caters to end-users. The learnings from this research will inform the methodology for future research using design thinking and artificial intelligence.

S.2.32-2

How to Combine Youth-centered Participatory Action Research with Systems Dynamics in a Youth-friendly Way? Insights from Two Projects

T. Altenburg^{1,2}, L. Klaufus^{1,2}, L. Madsen³, L. Demetriadou^{1,2}, C. Pawlowski³, J. Vargas^{1,2}, M. Chin A Paw^{1,2}

²Amsterdam Public Health Research Institute, Health Behaviors and Chronic Diseases, Methodology, Amsterdam, Netherlands, ³University of Southern Denmark, Department of Sports Science and Clinical Biomechanics, Odense, Denmark

S.2.32 Participatory Research in Health Promotion: How to apply participatory health research with emerging approaches and priority populations

Room 9, May 29, 2026, 8:00 AM - 9:00 AM

Purpose: An alarmingly low number of children and adolescents meet physical activity guidelines. Interventions aimed at promoting physical activity have had disappointing effects, potentially because they were 1) implemented top-down, overlooking the specific context and needs, and 2) insufficiently addressing the complex mechanisms driving physical inactivity. This presentation provides insights in how to combine youth-centered participatory action research (YPAR) combined with methods from systems dynamics in a youth-friendly way to develop interventions

SYMPOSIUM

that tackle the complex issue of physical inactivity.

Methods: We critically reflected on the methods and outcomes of two projects (LIKE & YoPA) that applied a YPAR x system dynamics approach aimed at developing 1) system maps that provide insights in the mechanisms driving youth's physical inactivity and 2) systemic actions that tackle these mechanisms, in collaboration with youth themselves. For both projects, reflections were gathered from reflection meetings with facilitators, discussing the activities that were conducted with youth, and the experiences of both the facilitators and youth.

Results: In both projects, youth were trained to conduct peer-research. Within LIKE, youth were guided in developing system maps and co-creating actions at different levels of the system. Participating youth experienced the phase of conducting peer-research and developing system maps as too long and boring. Facilitators stressed the challenge of developing and explaining systems-related activities to facilitate the development of system maps and actions. Within YoPA, youth were guided in developing stories explaining the (lack of) physical activity and co-creating actions necessary to change these stories. In the background, facilitating researchers developed system maps and prompting questions to develop systemic actions. Youth experienced the sessions as productive and facilitators mentioned the collected stories provided a rich source of data that enabled them to develop system maps.

Conclusion: To apply a YPAR x systems dynamics approach in a youth-friendly way, youth should not be bothered with understanding and applying all steps required in a system dynamics approach. Alternatively, facilitators should prepare easy-to-understand and fun activities, that guide the youth in understanding the mechanisms underlying physical inactivity and co-creating actions that tackle these mechanisms.

S.2.32-3

Co-creation of a Physical Activity and Sedentary Behavior Intervention with People with Severe Mental Illness: The INCREASER-study

L. Samyn¹

¹Ghent University, Ghent, Belgium

S.2.32 Participatory Research in Health Promotion: How to apply participatory health research with emerging approaches and priority populations

Room 9, May 29, 2026, 8:00 AM - 9:00 AM

Purpose: People with severe mental illness (SMI) have a life expectancy 10–20 years shorter than the general population, largely due to increased rates of cardiovascular disease, type 2 diabetes and metabolic syndrome. Low physical activity (PA) and high sedentary behaviour (SB) are crucial risk factors contributing to this disparity. Enhancing PA and reducing SB are therefore essential to improving health outcomes and reducing premature mortality in this population.

However, traditional interventions often fail to engage people with SMI, as they rarely address the specific barriers and daily realities these people face. This study aims to develop an accessible, engaging and effective PA and SB intervention for residents with SMI living in sheltered housing facilities, using a co-creation approach. Both residents and nurses will be involved to ensure the intervention aligns with lived experiences and professional practice. This participatory approach is innovative, as co-creation has not previously been applied to this population and in the specific context of sheltered housing.

Methods: The co-creation approach will be guided by the Intervention Mapping Protocol. First, a preparatory group discussion with key partners will be conducted to explore practical considerations and identify suitable methods for engaging participants. Subsequently, five to ten co-creation sessions will be organized, involving approximately 8–12 participants per session, including both residents with SMI and nurses working in sheltered housing. These sessions will address the first five steps of Intervention Mapping, focusing on needs assessment, defining objectives, intervention design and planning implementation. The discussion and co-creation sessions will be audio-recorded and transcribed for analysis.

Results: The co-creation sessions will produce a tailored intervention, which will later be implemented and tested for (cost-)effectiveness in a cluster-randomized controlled trial. During the symposium, we will present the activities and preliminary outcomes from each co-creation session.

Conclusion: This study will generate a context-sensitive intervention that reflects the experiences of people with SMI and the professionals who support them. It contributes to developing more effective, acceptable, and sustainable strategies to increase PA and reduce SB, and thereby supports healthier lives for people with SMI.

S.2.33-1

A Systems Approach to Food Security among Flemish Primary School Children: Identifying Drivers and Co-creating Actions

A.-S. Van Dijck¹, C. Dijkstra², D. Van de Sompel¹, K. Verbeke³, W. Van Lippevelde¹

¹Ghent University, Ghent, Belgium, ²Amsterdam UMC, Amsterdam, Netherlands, ³Let Us, Ghent, Belgium

S.2.33 Socio-economic inequalities: Schools as complex food systems: systemic insights and actions to advance food equity among children

Multipurpose Room, May 29, 2026, 8:00 AM - 9:00 AM

Purpose: Food insecurity among children and families is an increasing concern in Belgium. Addressing this challenge requires a systems dynamics approach to design and implement coordinated actions across multiple levels of the school food system. This study aims to deepen the understanding of food insecurity in Flanders and co-create a systemic action plan targeting the school food system to strengthen food security among primary school children.

Methods: A participatory systems approach will be applied in two Flemish municipalities. In each, three Group Model Building workshops will be held with up to 25 school stakeholders (e.g. local government, schools, social organisations). Stakeholders will build a causal loop diagram identifying drivers of food insecurity and leverage points for change. Actions will then be co-developed using the Action Scales Model. In parallel, interviews with 10–15 food-insecure families will provide essential context for the systems map.

Results: Co-creation in the first municipality took place in 2025. The resulting causal loop diagram included 64 factors and revealed six subsystems explaining the persistence of food insecurity: 1) socio-economic challenges reduce prioritisation of healthy food; 2) limited accessibility and complexity of aid services increase vulnerability; 3) absence of structural policy for school meal support; 4) school meal programs are not accessible; 5) social expectations and stigma influence food-related behaviours; and 6) an unhealthy food environment further undermines efforts to achieve food security. Based on these subsystems and the identified leverage points within, actions were developed (e.g. automatic granting of financial or food support, flexible meal pricing at schools, culturally adapted school menus, loyalty card to get reduction in supermarkets) and a transition agenda in collaboration with the municipality was set up. Findings will be finalised in spring 2026 with input from the second municipality.

Conclusion: Food insecurity is a systemic challenge that requires coordinated action across multiple levels. Building on the transition agendas co-created with the two municipalities, the next phase will focus on implementing these actions and establishing a framework for monitoring and evaluation over the coming years. This process aims to generate evidence on how systemic change can sustainably reduce food insecurity among children.

S.2.33-2

Understanding the Dynamics of Implementing the Norwegian School Fruit Programme – The FRESKO-project

M. Zolfaghari¹, N. Lien¹, C.L. Brandvik¹, K.-I. Klepp¹, B. Kopainsky², H.C Lie³, B. Meshkovska¹

¹University of Oslo, Department of Nutrition, Oslo, Norway, ²University of Bergen, Bergen, Norway, ³University of Oslo, Oslo, Norway

S.2.33 Socio-economic inequalities: Schools as complex food systems: systemic insights and actions to advance food equity among children

Multipurpose Room, May 29, 2026, 8:00 AM - 9:00 AM

Purpose: The FRESKO-project aimed to generate new knowledge on adoption, implementation and impact of school-based primary prevention interventions through combining implementation science and system dynamics using the Norwegian School Fruit Programme as a case. One sub-study aimed to investigate how the No Parental Payment version of the Programme (NPPP) was implemented and how it dynamically interacted with the school system. The resulting dynamic interactions were compared with the determinants of the Consolidated Framework for Implementation Research (CFIR).

Methods: Data were collected through a series of group model building (GMB) workshops at four schools offering the NPPP. Facilitated discussions between pupils and school personnel based on GMB scripts were held to elicit their perceptions of the NPPP's implementation dynamics and to create maps illustrating how implementation determinants interact with each other and each school's unique context. The four school maps were compiled into a

SYMPOSIUM

single map including all possible factors, which was overlaid by CFIR.

Results: Lack of communication with pupils about the program, the availability of food stores outside schools, and the NPPP's design (i.e. variation, quality of the fruit) weakened the reinforcing mechanism that fostered pupils' eating of fruit. Fruit not being eaten resulted in higher perceived implementation costs for schools having to manage leftovers and litter. Implementation processes, like reflecting, engaging, and adapting to reduce the implementation costs were tried by the schools. The design of the NPPP and mechanisms related to the goals and priorities of the schools, limited or constrained the success of these processes.

Conclusion: This study embedded implementation determinants within feedback processes that shape implementation dynamics, moving beyond a binary, linear understanding of determinants and implementation. Mapping CFIR onto systems' map was an innovative approach to facilitate an interdisciplinary communication. Lack of communication with pupils, the food stores outside schools, and the NPPP's design reduced its reach and inflated its costs. Moreover, schools' goals and priorities hampered the success of processes implemented to mitigate these issues. System dynamics tools, concepts, and insights proved useful for cultivating causal thinking and uncovering mechanisms, which are much needed to address pressing research questions in implementation research.

S.2.33-3

Understanding the Implementation of the National School Meals Programme in Amsterdam: A Systems-informed Qualitative Study

N. Droog¹, V. Busch², L. Jansen¹, W. Van Lippevelde³, C. Dijkstra¹

¹Amsterdam UMC, Amsterdam, Netherlands, ²Public Health Service (GGD) Amsterdam, Amsterdam, Netherlands, ³Ghent University, Ghent, Belgium

S.2.33 Socio-economic inequalities: Schools as complex food systems: systemic insights and actions to advance food equity among children

Multipurpose Room, May 29, 2026, 8:00 AM - 9:00 AM

Purpose: In 2023, the Dutch government launched the National School Meals Programme (NSMP) to address growing concerns about child poverty and children attending school without lunch. The programme provides subsidies for primary schools with many low-income students to offer meal support. This qualitative, systems-informed study explored how schools in Amsterdam implemented the NSMP, how it met their needs, and its perceived impact on children's nutrition, wellbeing, and school environments. By examining the interplay of beliefs, goals, and institutional structures that shaped local implementation, the study offers insight into how social, organisational, and policy factors interact within complex systems.

Methods: We conducted a qualitative evaluation of primary schools in Amsterdam. Participation and implementation models were mapped, followed by semi-structured interviews with 38 education professionals from 25 schools (principals, teachers, parent liaisons, and coordinators) and three focus groups to interpret and validate emerging themes. Data were analysed thematically using a grounded theory and systems-informed approach, focusing on implementation processes, perceived outcomes, and the underlying logics guiding schools' choices.

Results: Of the 97 eligible schools, 82% participated in the program. Implementation models included daily school-provided meals, externally delivered lunches, food packages, and grocery cards. Participants described the programme as vital for addressing (hidden) poverty and improving children's nutrition, wellbeing, and social inclusion. Daily in-school meals had the most visible effects, enhancing dietary intake, classroom equality, and student wellbeing, while fostering parental engagement and community cohesion. Externally delivered meals reduced staff workload but offered limited coverage, while food packages and grocery cards mainly alleviated financial stress. Schools' choices were strongly shaped by system-level factors such as beliefs about parental responsibility, perceived stigma, staff capacity, and alignment with educational values.

Conclusion: The NSMP has been widely adopted in Amsterdam and shows strong potential to enhance child nutrition, wellbeing, and inclusion. However, its effectiveness and sustainability depend not only on resources and logistics but also on deeper cultural, organisational, and policy dynamics. A systems approach that recognises and addresses these underlying structures is essential to embed meal provision as a structural and equitable component of the education system.

S.2.34-1

Improving Sleep among Infants: Development, Implementation and Evaluation of the ‘Sleep on Number 1!’ Program

S.2.34 Children and families: Promoting Sleep in Youth and Young Adults: Development, implementation and Evaluation of Sleep programs Targeting Sleep in Infants, Adolescents and Young Adults

Auditorium, May 29, 2026, 5:00 PM - 6:00 PM

Purpose: Sleep problems are common among young children, and parents often struggle to manage their infant’s sleep. Although sleep problems may have serious consequences, programs that sustainably promote sleep among infants remain scarce. The ‘Sleep on Number 1!’ program was developed for Dutch Youth Health Care (YHC). The program was based on science-based methods, needs assessments among parents and YHC professionals, and was co-created with stakeholders. It provided materials (e.g. communication cards), training and education for YHC professionals, and web-based educational materials for parents.

Methods: Several study designs were combined to evaluate the *Sleep on Number 1!* Program: (1) a process evaluation of the implementation in intervention regions (REAIM), (2) a quasi-experimental child record study comparing 6,000 pre- and post-intervention child records from intervention and control regions, with outcome variables being the number of sleep notes and advices provided by YHC professionals, and (3) a quasi-experimental sleep-monitoring study comparing sleep-related data (e.g. night awakenings) from 300 parents and infants between intervention and control regions at 10 weeks, 6 months, 9 months, 14 months and 24 months.

Results: The *process evaluation* showed that the training, symposium and e-learning module were followed by 65%, 66.5%, and 77%, respectively, of the YHC professionals. The professionals sent the webpage link with sleep information 715 times to parents; these webpages had 9,960 unique visits. A total of 320 sets of communication cards were distributed among YHC professionals.

Preliminary analyses of the *child records study* showed that the number of sleep notes per consultation almost doubled from pre- to post-test in the intervention regions ($M_{\text{pretest}} = .21$, $M_{\text{posttest}} = .40$), but not in the control region ($M_{\text{pretest}} = .42$, $M_{\text{posttest}} = .42$; $F(1,5979) = 321.735$, $p < .001$). Furthermore, the probability that parents received sleep advice from the YHC professional increased more in the intervention regions than in the control region ($OR = 1.96$, 95% CI [1.58–2.43], $p < .001$).

Data from the *sleep monitoring study* are currently being analyzed, and will be presented at the symposium.

Conclusion: The program was well implemented and used by YHC professionals and parents. Furthermore, it seems to lead to increased sleep-related communication and advice from YHC professionals.

S.2.34-2

Charge Your Brainzzz: Development, Implementation and Evaluation of a Whole-school Action Program Promoting Sleep among Secondary School Students

M.M. van Stralen¹, D. Heemskerk^{1,2}, L. Smeijsters¹, V. Busch²

¹Vrije Universiteit Amsterdam, Health Sciences, Amsterdam, Netherlands, ²GGD Amsterdam, Healthy Living, Amsterdam, Netherlands

S.2.34 Children and families: Promoting Sleep in Youth and Young Adults: Development, implementation and Evaluation of Sleep programs Targeting Sleep in Infants, Adolescents and Young Adults

Auditorium, May 29, 2026, 5:00 PM - 6:00 PM

Purpose: Sleep deprivation is a growing concern among adolescents, negatively affecting their mental, physical, and brain health. Many school-based interventions promoting sleep health have shown limited effectiveness, possibly because they overlook the complexity of sleep. Systems thinking is acknowledged as a promising approach to

SYMPOSIUM

understand and respond to complex health problems. This study aimed to systematically develop, implement, and evaluate *Charge Your Brainzzz*, a scientifically grounded, whole-school action program designed to promote healthy sleep among secondary school students.

Methods: A systems thinking approach was applied in developing the whole-school action program *Charge Your Brainzzz*, guided by the Intervention Mapping protocol to integrate theory- and evidence-based behavior change methods. Adolescents, parents, education- and health professionals were actively involved through co-creation sessions to ensure contextual fit. The program includes classroom lessons for first-year students, parent-focused components (e.g. interactive parental evening), a screening and discussion tool for care coordinators, and school policy recommendations (e.g. no evening communication and later school start times).

A mixed-methods pilot study among first-year pre-vocational students from eight Dutch secondary schools evaluated both the implementation process and preliminary effectiveness. Quantitative analyses used mixed models in Stata to assess changes in sleep outcomes over time. Qualitative interviews with key stakeholders were analyzed using directed content analysis in MAXQDA (2018), following the Determinants of Innovation model.

Results: Students ($N = 762$, 56% boys; age 12.6 ± 0.6) showed significant improvements in sleep duration ($b = 12.8$; 95%CI: 6.8–18.8), sleep-related knowledge ($b = 0.10$; 95%CI: 0.07–0.12), and attitudes towards sleep ($b = 0.14$; 95%CI: 0.05–0.23) after implementation. No changes were observed in sleep hygiene practices. The program was generally well-received; however, some components, particularly school policy and care coordination, were not fully implemented.

Conclusion: Preliminary findings suggest that Charge Your Brainzzz is a promising systems-based program to improve adolescent sleep. A large-scale controlled trial is currently underway, and short-term findings from this study will also be presented at the conference. These insights into the program's development, impact, and implementation process provide valuable guidance for scientists applying systems thinking, as well as for schools and public health organizations aiming to promote sleep.

S.2.34-3

Development and Evaluation of a Program Promoting Sleep Health among University Students

S. Fakroune^{1,2}, H. Ivers¹, S. Van den Broucke², C. Morin¹

¹Laval University, Centre d'Étude des Troubles du Sommeil (CETS), Québec, Canada, ²Université Catholique de Louvain (UCLouvain), Psychological Sciences Research Institute (IPSY), Louvain-la-Neuve, Belgium

S.2.34 Children and families: Promoting Sleep in Youth and Young Adults: Development, implementation and Evaluation of Sleep programs Targeting Sleep in Infants, Adolescents and Young Adults
Auditorium, May 29, 2026, 5:00 PM - 6:00 PM

Purpose: University students are at increased risk of developing sleep problems, which can impair health, mental wellbeing, and academic performances. Sleep health as defined by Buysse (2014), is a multidimensional concept not focusing only on harmful symptoms but offering a broader perspective and target for prevention initiatives. Although promoting sleep health might be a strategy to prevent students from reaching clinical thresholds, interventions targeting it remain scarce for this group. Thus, the aim of this study was to develop and evaluate a program for improving sleep health and its targeted psychosocial determinants for university students.

Methods: A randomized trial ($N = 82$) with a waitlist control group evaluated a program combining behaviour change techniques (BCTs), motivational interviewing (MI) principles, and inspired content from cognitive behavioural therapy for insomnia (CBT-I). It was delivered in small groups and lasted three weeks with 90-minutes sessions each week. Instruments used were sleep diaries validated questionnaires such as RU-SATED for sleep health and SHPS for sleep hygiene, questionnaires about beliefs underlying sleep hygiene (i.e. drawn from the Theory of planned behaviour), about self-efficacy (i.e. task, maintenance, and recovery) in behaviour change, and a qualitative process evaluation tool. Data were collected between January 2024 and July 2025 at pretest, posttest, and 3-month follow-up, and analyzed with multilevel mixed models.

Results: Significant interaction of time and groups indicated that the experimental group showed greater improvements of intention for good sleep hygiene $F(1,76) = 10.991$, $p = .001$, $d = .92$, sleep duration $F(1,73) = 7.943$, $p = .006$, $d = .52$ and sleep efficiency $F(1,76) = 7.885$, $p = .006$, $d = .58$ compared to the control group. In addition, a model including the three time points and all participants who received the program revealed significant main effects of time across several outcomes (all $p < .05$), showing improvement for sleep health, duration, efficiency, hygiene, behavioural control and intention, and self-efficacy.

Conclusion: These findings support the use of BCTs, MI principles, and CBT-I content to improve students' sleep health. Further replication with larger sample and greater student involvement in the program process is recommended to strengthen and extend these findings.

S.2.35-1

Assessing Spatial and Policy Indicators for Healthy and Sustainable Cities: Insights from the Application of the GHSCI Framework in Spain

X. Delclòs-Alió¹, A. Puig-Ribera², A. Queralt³, M. Domínguez¹, A. Colom⁴, A. Arranz-López⁵, J. Molina-García⁶

¹Universitat Rovira i Virgili, Departament de Geografia, Vila-seca, Spain, ²University of Vic-Central University of Catalonia, Research Group in Sports and Physical Activity (GREAF), Vic, Spain, ³University of Valencia, Grup de Recerca en Activitat Física i Promoció de la Salut (AFIPS), Department of Nursing, Valencia, Spain, ⁴Health Research Institute of the Balearic Islands (IdISBa), Research Group in Nutritional Epidemiology and Cardiovascular Physiopathology (NUTRECOR), Palma, Spain, ⁵Zaragoza Logistics Center (ZLC), Zaragoza, Spain, ⁶University of Valencia, Grup de Recerca en Activitat Física i Promoció de la Salut (AFIPS), Department of Teaching of Physical Education, Arts and Music, Valencia, Spain

S.2.35 Policies and environments: Advancing Global Evidence for Active, Healthy, and Sustainable Cities: Cross-Regional Insights from the Global Observatory of Healthy and Sustainable Cities

Room 1, May 29, 2026, 5:00 PM - 6:00 PM

Purpose: Implementing urban policies that enhance accessibility, sustainability, and active mobility is fundamental to promoting healthier cities. Such policies require high-quality, evidence-based data to inform their design, implementation, and evaluation. This study assesses the extent to which the ten largest cities in Spain support healthy and sustainable urban environments through spatial and policy indicators.

Methods: The Global Healthy and Sustainable City Indicators (GHSCI) framework, an evidence-based and open science toolbox, was used to analyze a set of spatial and policy indicators in the cities of Barcelona, Bilbao, Las Palmas de Gran Canaria, Madrid, Málaga, Murcia, Palma, Sevilla, Valencia and Zaragoza, housing over 14 million residents. Spatial indicators included standardized measures of accessibility and urban design (i.e. access to daily destinations and public open spaces, public transport, and walkability). The GHSCI policy checklist was used to assess the integration of health and sustainability objectives in urban and transport planning frameworks in Barcelona, Las Palmas de Gran Canaria, Palma, Valencia and Zaragoza.

Results: Spanish cities are generally aligned with healthy and sustainable urban design principles, derived from compact, mixed-use neighborhoods with medium to high population and intersection densities. About 60% of residents have walking access to daily amenities such as food stores and kiosks, while 90% live within walking distance of public open spaces, although access to large green areas remain scarcer due to compact urban morphology. Walkability peaks in historic centers but declines toward the urban contours; notably, Barcelona and Bilbao lead with over 60% of residents in highly walkable neighborhoods. Cities performed high in relation to policy presence that support health and sustainability. However, these policies have room for improvement in terms of the inclusion of evidence-informed standards and measurable targets.

Conclusion: Applying the GHSCI framework in Spain demonstrates the feasibility and value of standardized spatial and policy indicators for large-scale, cross-city comparisons. The experience highlights the need for local engagement to ensure data accuracy and policy relevance. Spatial and policy indicators offer valuable insights for local and regional planners to assess inequalities in access to health-promoting environments and to design and evaluate more equitable, active, and sustainable cities.

S.2.35 Policies and environments: Advancing Global Evidence for Active, Healthy, and Sustainable Cities: Cross-Regional Insights from the Global Observatory of Healthy and Sustainable Cities Room 1, May 29, 2026, 5:00 PM - 6:00 PM

Purpose: The Brazilian Observatory of Healthy and Sustainable Cities (OCSS) was created to integrate Brazilian cities into a global network of cities that address the determinants of active living while applying local lenses to inform policy action. We aim to develop and test locally relevant urban health indicators that are globally comparable. Our approach included applying Community-Based System Dynamics (CBSD) to map the macro-determinants of physical activity via a conceptual model and causal loop diagrams, leveraging artificial intelligence (AI) to analyze street-level imagery for built environment inequities, and building capacity through multi-city collaborations.

Methods: In four Brazilian cities (Curitiba, Florianópolis, Pelotas, and Rio de Janeiro), local teams compiled urban policy documents and built environment data. A CBSD workshop produced CLDs illustrating factors influencing physical activity. GIS-based indicators (intersection and population density, public transit access, and open space access) were calculated to assess walkability using global observatory tools. An AI-based analysis of Google Street View images was piloted to quantify built environment features. Additionally, researchers participated in training workshops and a hybrid international course to standardize data collection and analysis methods.

Results: The CBSD process yielded a conceptual model with six priority areas for physical activity promotion in urban contexts. Policy mapping identified numerous relevant policies but revealed fragmented sources and a lack of measurable policy targets. Baseline spatial indicators showed differences in walkability and amenity access between cities, and an AI-based assessment of street images illustrated disparities in built environments across socio-economic contexts, though few studies explicitly address spatial equity. Local capacity was strengthened through training researchers, but limited data availability and difficulties in harmonizing indicators across cities remained challenges.

Conclusion: OCSS demonstrates an innovative multi-city collaboration that bridges research and policy for healthy, sustainable cities. Integrating locally tailored indicators within a global observatory framework provides actionable evidence to guide urban planning and public health interventions. The combination of participatory system dynamics and AI-enhanced spatial analysis yields a comprehensive perspective on how urban environments affect physical activity and health. This cross-city partnership and capacity-building model offers a scalable approach for advancing active, equitable urban environments in Brazil and beyond.

S.2.35 Policies and environments: Advancing Global Evidence for Active, Healthy, and Sustainable Cities: Cross-Regional Insights from the Global Observatory of Healthy and Sustainable Cities Room 1, May 29, 2026, 5:00 PM - 6:00 PM

Purpose: The urban growth projected by 2050 will mainly occur in lower- and middle-income countries (LMICs), which face high disease burdens, severe climate vulnerabilities, and often have fewer resources than high-income countries

(HICs) to provide infrastructure and services for their rapidly growing populations. Reducing health inequities is a priority, yet most evidence on health-enhancing city planning comes from HICs, highlighting crucial gaps in how LMICs integrate public health. This study assessed the extent to which LMIC city planning policies align with evidence-based indicators for health and sustainability goals. We explore policy analysis challenges and institutional and governance barriers to policy implementation.

Methods: A comparative policy content analysis was conducted across twelve cities in seven LMICs, using the indicators from the Global Observatory for Healthy and Sustainable Cities. Urban and transport planning documents were systematically reviewed using a framework of evidence-based indicators related to integrated city planning, walkability and destination access, public open space, public transport, and air quality. Chinese cities' policies were assessed against additional indicators, including traffic safety, nature-based solutions, healthy food environments and climate disaster risk reduction. Policies were assessed for measurable targets, alignment with public health evidence, and institutional mechanisms for implementation and monitoring.

Results: Most planning frameworks acknowledged the importance of health and sustainability but lacked operational, measurable targets to support active mobility. Policy coverage across the indicators varied widely: São Paulo (Brazil; 69%) and the six Chinese cities (72-75%) performed relatively well, whereas other cities—Maiduguri (Nigeria; 23%), Bangkok (Thailand; 29%), and Hanoi (Vietnam; 33%)—exhibited the largest policy gaps. Key shortcomings were observed in integrating land-use and transport planning, ensuring equitable access to destinations, and prioritising walking, cycling, and public transport. Institutional fragmentation, limited technical capacity, and competing economic priorities further hindered implementation. However, select cities incorporated measurable targets to improve public transport accessibility and walkability.

Conclusion: Urban planning policies in LMICs are at a critical juncture. Strengthening their capacity to embed measurable, health-oriented indicators within planning frameworks is essential for reducing rising health inequities. Investing in cross-sectoral governance, data systems, and local capacity building can help operationalise global evidence into locally relevant policy actions.

S.2.36-1

Effectiveness of a Peer-volunteer-led Active Ageing Programme in Preventing Physical Decline among Older Adults: Results from the Active, Connected, Engaged (ACE) Randomised Controlled Trial

A. Stathi¹, J. Withall¹, D. Crone², H. Hawley-Hague³, M. Western⁴, K. Chatwin¹, A. Davies³, Z. Szekeres², R. Playle⁵, E. Frew¹, S. Fenton¹, M. Hillsdon⁶, K. Jolly¹, C. Pugh², M. Wright⁵, J. Baxter⁵, C. Todd³, E. Boulton⁷, C. Greaves¹

S.2.36 Ageing: Innovative Approaches to Promote Physical Activity and Prevent Mobility Decline in Older Adults: Evidence from Pragmatic Randomised Controlled Trials in the UK and Australia

Room 2, May 29, 2026, 5:00 PM - 6:00 PM

Purpose: Mobility limitations escalate with age, contributing to loss of independence, increased fall risk, progression to frailty, and reduced quality of life. The ACE trial—the largest study of its kind—aimed to evaluate the effectiveness of a six-month, peer-volunteer-led intervention designed to help older adults at risk of mobility disability become more physically and socially active, with the goal of slowing or reversing functional decline associated with ageing.

Methods: This two-arm, pragmatic randomised controlled trial was conducted with 528 community-dwelling older adults aged 65+ (mean age 77.5; 65% female; 55% with multiple long-term conditions), at risk of mobility disability (Short Physical Performance Battery [SPPB] score 4–9) and 227 peer volunteers aged 55+ (59% female). Participants were randomly allocated to either the ACE intervention (n = 265) or control arm (n = 263) across four UK sites: Bristol, Cardiff and the Vale of Glamorgan, Manchester, and Stoke-on-Trent. The ACE intervention is a 6-month programme underpinned by behaviour change theory, whereby peer volunteers are paired with participants and offer them individually tailored support to engage them in local physical and social activities, aiming to improve lower limb mobility and increase their physical activity. The primary analysis used a linear mixed model including group allocation, site, baseline, 6- and 18-month SPPB scores (the primary outcome).

Results: The difference between the two groups, was statistically significant and clinically meaningful at 18 months (SPPB adjusted mean difference 0.6 points, 95%CI: 0.2 to 1.0; p=0.005). The difference at 6 months (post intervention) was also significant (SPPB adjusted mean difference 0.4 points, 95%CI: 0.0 to 0.8; p=0.031).

SYMPOSIUM

Conclusion: For older adults at risk of mobility disability, the ACE randomised controlled trial demonstrated that a six-month peer volunteering programme delivered sustained, clinically meaningful improvements in lower limb physical function. A multi-level mixed methods process evaluation, incorporating systems mapping, will unpack the mechanisms behind this success. Mobilising peer-volunteers could be a scalable approach to promote active ageing in community settings.

S.2.36-2

Physical Activity Coaching for Adults with Walking Limitations: Results of the Comeback Hybrid Type 1 Effectiveness-implementation Randomised Controlled Trial

S.2.36 Ageing: Innovative Approaches to Promote Physical Activity and Prevent Mobility Decline in Older Adults: Evidence from Pragmatic Randomised Controlled Trials in the UK and Australia

Room 2, May 29, 2026, 5:00 PM - 6:00 PM

Purpose: Walking limitations are a form of disability that is particularly common in individuals with chronic health conditions and older adults, leading to high rates of physical inactivity and negative physical and mental health and quality of life consequences in these traditionally underserved populations. The ComeBACK trial aimed to evaluate the effectiveness of two scalable physical activity interventions, telephone-based health coaching (*Coaching to ComeBACK*) and unidirectional text messaging (*Texting to ComeBACK*), compared to a *waitlist control group* in adults with self-reported walking limitations.

Methods: This three-arm, pragmatic randomised controlled trial was conducted with 512 community-dwelling adults in Australia (mean age 69 years; 76% women; 51% reporting multimorbidity). Participants were randomly assigned to *Coaching to ComeBACK* (n=172), *Texting to ComeBACK* (n=171) or *waitlist control* (n=169). The primary outcome was device-measured average daily steps over one week at six months. Secondary outcomes included physical function, mental well-being, quality of life, goal attainment and falls. Between-group differences were estimated using linear regression and longitudinal models.

Results: At six months, participants in the *Coaching to ComeBACK* group had higher average daily steps (mean 7256, SD 3736) than both *waitlist control* (mean 6526, SD 3003; adjusted between-group difference 931 steps, 95%CI: 409 to 1452; $p=0.001$) and *Texting to ComeBACK* (mean 6529, SD 3029; between-group difference 571 steps, 95%CI: 58 to 1084, $p=0.03$). *Coaching to ComeBACK* also led to greater improvements in goal attainment and reductions in walking limitations due to lower limb or back pain.

Conclusion: Health coaching is a more effective intervention than texting or no intervention for improving physical activity in adults with walking limitations. Its tailored, person-centred approach supports equitable access to physical activity opportunities for populations often excluded from physical activity research, informing future models of care that can prioritise diversity and inclusion of people with disability.

S.2.36-3

The Efficacy of Strength and Tai-Chi Exercise Snacking on Older Adults Physical Function: A 12-week Randomised Controlled Trial

M.J Western¹, I.J. Liang², S. Williams¹, P. McGuigan¹, D. Thompson¹, O.J Perkin¹

¹University of Bath, Department for Health, Bath, United Kingdom, ²University of Dundee, Dundee, United Kingdom

SYMPOSIUM

S.2.36 Ageing: Innovative Approaches to Promote Physical Activity and Prevent Mobility Decline in Older Adults: Evidence from Pragmatic Randomised Controlled Trials in the UK and Australia

Room 2, May 29, 2026, 5:00 PM - 6:00 PM

Purpose: Preventing frailty in older age is crucial for reducing fall-risk and maintaining independence, community engagement and a good quality of life. In the UK just 20% of adults aged 65 years or older meet the recommended muscle strength and balance guidelines to maintain physical function, with common participation barriers being low-self efficacy for exercise and dislike of leisure settings, lack of time, and fear of injury. Having established feasibility and acceptability of home-based strength and tai-chi 'exercise snacking' as simple and engaging option for older adults, this research aimed to explore its efficacy of on improving physical function.

Methods: Mobility impaired, inactive, older adults (n=90) were randomised to undertake either 12-weeks of progressive twice-daily exercise snacks, consisting of 5-minutes of strength and 5-minutes of tai-chi exercises, or a waitlist control. Participants physical function was assessed using the strength and balance components of the Short Physical Performance Battery (SPPB), single leg standing balance, and 60s sit-to-stand test remotely via videoconferencing at baseline, 4-, 8-, and 12-weeks. A subset of intervention participants (n=26) underwent semi-structured interviews to discuss their experiences. Quantitative data were analysed using linear mixed models, and qualitative data were analysed using a deductive framework analysis based on the theoretical framework of acceptability.

Results: Intervention participants improved their SPPB-measured strength (estimated mean difference in week 4: 1.05; week 8: 0.79; and week 12: 0.79) and balance (week 4: 0.71; week 8: 0.57; and week 12: 0.65) relative to the control group. Timed-up-and-go (week 4: 1.94; week 8: 1.58; and week 12: 1.1) and total SPPB scores (week 4: 2.24; week 8: 1.79; and week 12: 1.76) were also improved in the intervention group compared to the control group in a lab subset participants (n=40). The qualitative findings indicated the programme was accessible and personally beneficial, and in many cases raising their self-efficacy for future physical activity.

Conclusion: Just 10-minutes per-day of progressive strength exercise and tai-chi snacking programme may lead to clinically meaningful improvements in physical function over 12-weeks, presenting a low-cost, scalable, way to safely increase strength and balance at home amongst older adults with mobility limitations.

S.2.37-1**Voices from Within: How the Built Environment Supports Physical Activity in Youth and Adult Inmates**M. Giné-Garriga¹, C. Palma², R. Romeva², S. Signo², M.C. Isanta², M. Cortés³, E. Sebastiani²

¹Blanquerna-Universitat Ramon Llull, School of Health Sciences, Barcelona, Spain, ²Blanquerna-Universitat Ramon Llull, School of Psychology, Education and Sport Sciences, Barcelona, Spain, ³Department of Justice, Government of Catalonia, Barcelona, Spain

S.2.37 Participatory Research in Health Promotion: Addressing Key Community Physical Activity Program Needs in Spanish-speaking Nations through Participatory Citizen Science

Room 3, May 29, 2026, 5:00 PM - 6:00 PM

Purpose: The prison population in Europe has increased by 5% since 2020, despite efforts to reduce inmate numbers. In Spain, youth incarceration rates are rising faster than those of adults, with many young detainees spending extended periods in preventive detention. Incarceration is often associated with unhealthy behaviours including smoking, substance use, sedentary lifestyles, and irregular diets that contribute to higher rates of acute and chronic physical and mental health conditions. Physical activity (PA) levels among inmates are significantly lower than those of the general population. To develop strategies promoting PA among incarcerated youth and adult males, we applied the *Our Voice* citizen science method to explore how the built environment can support increased PA.

Methods: Twenty-six adult (mean 39.5 ± 12.3 years) and 31 youth (mean 15.3 ± 3.2 years) male inmates from one adult and one youth prison in Catalonia, Spain, participated. Multiple recruitment strategies ensured diverse representation. We implemented the four-step *Our Voice* method to identify how common prison spaces could be modified to promote movement. Participants collected data using the Discovery Tool mobile app, including geotagged photographs, audio-textual narratives, and simple positive/negative ratings via emojis. Two discussion groups were held to organize findings and develop strategies to leverage local assets and address barriers. The process culminated in a facilitated, participatory action planning session, subsequently shared with prison administration and a policymaker from the Department of Justice.

Results: Participants identified built environment features influencing PA engagement, including the availability and condition of outdoor spaces, safety concerns, accessibility of exercise equipment, and social support from peers.

SYMPOSIUM

Both youth and adults emphasized flexible schedules, supervised yet autonomous access to activity areas, and motivational cues such as signage and designated exercise zones. Youth valued engaging, game-like spaces, whereas adults emphasized privacy and quiet areas. The collaborative process fostered empowerment and generated feasible, participant-driven recommendations for environmental modifications to support PA.

Conclusion: Engaging incarcerated populations in citizen science provides insights into environmental factors that facilitate or hinder physical activity. Participatory approaches like *Our Voice* can enhance inclusion, agency, and tailored interventions, informing strategies to promote PA behaviour change among vulnerable populations.

S.2.37-2

Citizen Science in Active Mobility to School Programs in Bogotá, Colombia: Empowering the Voices of Children and Young People

O. Sarmiento¹, G.A. Alarcón Garavito¹, N. Solórzano¹, J. Benavides¹, L. Zarate¹, E. de la Vega Taboada², B. Chrisinger³, D. Oviedo⁴, A. King²

¹Universidad de los Andes, School of Medicine, Bogotá, Colombia, ²Stanford University, Department of Epidemiology & Population Health, School of Medicine, Palo Alto, CA, United States, Stanford, United States, ³Tufts University, Department of Community Health, Bogotá, United States, ⁴University College London, The Bartlett Development Planning Unit, London, United Kingdom

S.2.37 Participatory Research in Health Promotion: Addressing Key Community Physical Activity Program Needs in Spanish-speaking Nations through Participatory Citizen Science
Room 3, May 29, 2026, 5:00 PM - 6:00 PM

Purpose: The study applied the *Our Voice* citizen science method to capture students' perceptions of routes, highlight facilitators and barriers, and strengthen their agency in advocating for solutions

Methods: Active School transport represents a promising strategy to promote healthy lifestyles. In Bogotá, Colombia, two large-scale programmes, Ciempiés Caminos Seguros (CCS) and Al Colegio en Bici (ACB), encourage students to commute to school on foot or by bicycle. A total of 42 students aged 8–13 years from four public schools enrolled in CCS and ACB were included in the study. Citizen scientists described their routes using the Stanford Discovery Tool app, accompanied by photos and audio narratives. Their contributions were analysed through a socio-ecological lens to examine built environment, social, and behavioural factors shaping mobility.

Results: Citizen scientists identified positive features such as the presence of trees, clean and shaded sidewalks, and safe walking and cycling infrastructure that made their trips more enjoyable. They particularly valued the sense of safety, care, and companionship provided by the programme guides, who fostered trust and community along the way. Students also appreciated the friendships formed and the fun of travelling together. They also reported barriers including litter, poorly maintained pavements, defective traffic signage, aggressive behaviours from pedestrians, and risks of crime and collisions.

Two community meetings gathered students, guides, school staff, local authorities, and mobility and safety officials, illustrating the diverse governance and stakeholder structures supporting CCS and ACB. In these meetings, the citizen scientists presented findings through interactive activities, engaged in roundtable discussions to co-create solutions, and defined responsibilities, actions, and timelines for follow-up. This process fostered accountability and collaborative local governance.

Conclusion: Citizen scientists expressed strong enthusiasm to continue with CCS and ACB. The process led to concrete actions, including removing a dangerous tree near a school, increasing the presence of safety authorities, and collaborating with Local Bicycle Councils to extend programmes to other schools and districts. Crucially, the initiative promoted intersectoral dialogue between students, schools, and local authorities to strengthen active school mobility. Findings underscore the transformative potential of participatory approaches to advance equity-centred urban planning and mobility policies for students in Latin America.

S.2.37-3

Citizen Science to Address Interpersonal Violence and Support Safeguarding in Sport: An *Our Voice* Study Among Elite Female Athletes in Lima, Peru

M. Pedersen¹, T. Simich Padilla², M. Scarafia², D. Cino Barreda², F. Borges De Sanctis³, A.C. King⁴

¹University of Montana, School of Public and Community Health, Missoula, United States, ²Universidad Peruana de Ciencias Aplicadas, Lima, Peru, ³Fundación Deporte en Igualdad, Lima, Peru, ⁴Stanford University, Department of Epidemiology and Population Health, Stanford, United States

S.2.37 Participatory Research in Health Promotion: Addressing Key Community Physical Activity Program Needs in Spanish-speaking Nations through Participatory Citizen Science

Room 3, May 29, 2026, 5:00 PM - 6:00 PM

Purpose: Interpersonal violence (IV) exists across individual/interpersonal and contextual levels in sport. Recent examinations of IV and safeguarding (all proactive measures to prevent and respond to IV) in sport have emphasized the value of using a socioecological approach to examine the relationships between sportspeople and their environments. Including athlete voices has become increasingly relevant, yet existing research often fails to capture the complexity of their experiences within their environments. The *Our Voice* method blends citizen science and mobile technology to enable audiovisual and geotagged data collection and narrative documentation by athletes, and includes collective review of data to generate deeper understandings and holistic solutions.

Methods: The purpose of this study was to use the *Our Voice* method to examine the collective experience of elite female athletes living in Lima, Perú, as it relates to IV and safeguarding in sport. The study team used a community-engaged research approach, collaborating across universities, a grassroots organization, and the Peruvian National Softball Federation to recruit athletes to engage in the *Our Voice* method. Data collection included pre-post surveys, geotagged photos and qualitative narrative comments collected through the Stanford Discovery Tool mobile app, and qualitative data through group forums where athletes reviewed their own collective data to generate thematic findings based on barriers, facilitators, and recommendations for solutions and action.

Results: Elite female athletes (N=18) participated in the *Our Voice* method, including a pre-intervention relationship building session, a mobile data collection period yielding 55 data points, and 14 facilitated group meetings. The qualitative data were organized into six categories that related to IV and safeguarding across socioecological levels: safety, infrastructure, sanitation, street harassment, transportation, and outreach. For each category, athletes identified examples, recommendations for improvement, and an action plan for change. Athletes presented findings to stakeholders in an advocacy presentation.

Conclusion: This study examined IV and safeguarding among elite athletes living in Lima, Perú, using a community-engaged citizen science approach. Findings align with recent consensus recommendations to encourage sport that is athlete-centered, and to engage with unheard voices and integrate global perspectives into safe sport.

S.2.38-1

Scaling up a Co-created School-based Sleep Intervention through School-led Co-adaptation

M. Verloigne¹, B. Deforche¹, A. Vandendriessche¹

¹Ghent University, Public Health and Primary Care, Ghent, Belgium

S.2.38 Participatory Research in Health Promotion: Why don't you ask us? Co-creating and co-adapting school health promotion for, with and by students, teachers and professionals

Room 4, May 29, 2026, 5:00 PM - 6:00 PM

Purpose: Adequate sleep is essential for adolescents' mental, cognitive, and physical health, yet recent trends show declining sleep duration and quality among young people. To address this, a school-based healthy sleep intervention was previously co-created with students and teachers and evaluated in a participatory research project. The next step is to scale up this intervention across schools, while ensuring that it remains contextually relevant. Therefore, school-led co-adaptation is required, in which diverse people at school (including students) tailor the intervention to their specific school setting. This study aims to evaluate the process of school-led co-adaptation of the healthy sleep intervention using qualitative research.

SYMPOSIUM

Methods: Five secondary schools (focusing on students aged 12–14) in Flanders, Belgium, were already recruited. Between November 2025 and January 2026, a team of school members (teachers, other staff, and students) will independently adapt the intervention using a structured online step-by-step support manual. This process includes assessing the local context and adapting the previously co-created intervention materials and implementation strategies. Schools will then implement their adapted intervention. After the co-adaptation phase, semi-structured focus groups/interviews will be conducted with all participating co-adapters in each school. Data will be analysed thematically using MAXQDA.

Results: During the ISBNPA conference, we will present findings on how the diverse collaborators within the schools navigate this autonomous co-adaptation process, the challenges encountered, and the conditions that facilitate successful local ownership of the healthy sleep intervention.

Conclusion: This study will provide insight into the feasibility of autonomous co-adaptation of complex school health interventions, which is a necessary step to scale up previously co-created interventions.

S.2.38-2

Co-creation Process in YOU BEAT 'M: An Integral Lifestyle Approach for Dutch Vocational Students

C. Veldhuis¹, N. Bartelink¹, G. ten Hoor², P. van Assema¹, S. Kremers¹, K. Bessems¹

¹Maastricht University, Health Promotion, Maastricht, Netherlands, ²Maastricht University, Work and Social Psychology, Maastricht, Netherlands

S.2.38 Participatory Research in Health Promotion: Why don't you ask us? Co-creating and co-adapting school health promotion for, with and by students, teachers and professionals

Room 4, May 29, 2026, 5:00 PM - 6:00 PM

Purpose: Adequate dietary intake and physical activity can prevent non-communicable diseases such as type 2 diabetes and different forms of cancer. Targeting students in Dutch vocational schools (mbo's) through lifestyle interventions can support these behaviours but effective lifestyle interventions are currently missing for this group. In the YOU BEAT 'M project four existing effective interventions for other groups are adapted for vocational schools in a process of co-creation with, for and by vocational schools as building blocks of an integrated approach. These interventions are Good Affordable Food, Up for Cooking, Power Food and Focus on Strength. This study presents the findings of the co-creation process with students.

Methods: From April to July 2025, 18 co-creation sessions were conducted with students and teachers in vocational schools, in which adapted elements of the existing interventions in new working formats were tested. Additionally, two co-creation sessions with professionals were organised on the preliminary results of the student sessions and how these could be translated into YBM.

Results: Most of the content of the original interventions was relevant, but adaptations were required in working formats. Working in small groups, short clear instructions followed by active working methods, and diversity in topics with competitive elements works well for students. Professionals and teachers preferred a flexible program with choice activities to fit the needs of their groups.

Conclusion: Co-creation with students, teachers and professionals is a valuable method to adapt existing interventions for a new setting. While intervention content could be kept equal to the original interventions, working formats changed a lot. Next steps are to evaluate YOU BEAT 'M in a real-world setting.

S.2.38-3

Co-creating Implementation Tools to Support Schools in Navigating their Unique and Dynamic Context: A Dutch Case Study with Healthy School-coordinators and Healthy School-advisors

B. van Dongen¹, V. Kruitwagen-van de Gaar², C. Renders¹

¹Vrije Universiteit Amsterdam, Health Sciences, Amsterdam, Netherlands, ²National Institute for Public Health and the Environment (RIVM), Centre for Healthy Living, Bilthoven, Netherlands

SYMPOSIUM

S.2.38 Participatory Research in Health Promotion: Why don't you ask us? Co-creating and co-adapting school health promotion for, with and by students, teachers and professionals

Room 4, May 29, 2026, 5:00 PM - 6:00 PM

Purpose: Whole-school approaches that focus on health education, policies and creating a healthy school environment are increasingly being adopted in many countries. Implementing such a system-wide change can be challenging, because schools are dynamic organizations with constantly interacting and evolving circumstances. In the Dutch context, schools are stimulated to work with the (whole-school) 'Healthy School' (HS)-approach. To support schools implementing this approach, several co-created implementation tools recently have been developed. We share two examples.

Methods: Two types of implementing stakeholders are of particular importance in the HS-approach: a) Healthy School-coordinators (HSC): professionals working in schools and responsible for coordinating implementation, b) Healthy School-advisors (HSA): professionals working at regional Public Health Services and responsible for expertise and support to HSC. A co-creation process enabled by participatory research between HSC, HSA, national representatives and researchers was used, following several phases:

- 1) identifying needs and wants,
- 2) co-creations of tools,
- 3) pilot-testing, and
- 4) embedding on a national level.

Results: The HSC-project developed an online implementation tool in which stakeholders can monitor their progress and get tailored information for next implementation steps based on their unique context. Currently, national implementation is monitored by a group of national representatives and stakeholders in schools in order to optimize usability and integrating the tool in daily practice. The HSA-project identified five roles to better support schools during implementation processes: a central navigator role, and four adjacent roles (linking pin, expert in the field, critical friend and ambassador). These roles provided the basis for development of a training on how to work in a context-oriented manner to support schools with unique context. This training was well received and is now embedded in the regular professional development offered to HSAs nationwide.

Conclusion: Co-creation in both projects proved essential to develop tools suitable for implementing stakeholders. Through collaboration between practice, policy and research, tools could be developed based on scientific insights as well as the reality of daily practice of implementing stakeholders and the momentum of national structures of the Dutch HS-approach. Simultaneously, maintaining a balance between fidelity and adaption remains challenging when starting from co-creation processes.

S.2.39-1

From Alliance to Action: Identifying Problems and Co-creating Solutions for Childhood Obesity Prevention in a Low-socioeconomic District of Madrid

D.J. Mora¹, S. Pino², M. Franco^{1,3,4}, V. Sanz², L. Cereijo¹

¹University of Alcalá, Public Health and Epidemiology Research Group, Faculty of Medicine and Health Sciences, Alcalá de Henares, Spain, ²Madrid Salud, Madrid, Spain, ³BC3 Basque Centre for Climate Change, Adaptation Lab, Leioa, Spain, ⁴Johns Hopkins Bloomberg School of Public Health, Department of Epidemiology, Baltimore, United States

S.2.39 Motivation and behavior change: Co-creating a toolbox to improve the implementation of childhood obesity prevention policies in low socioeconomic municipalities – the OBCT Project

Room 5, May 29, 2026, 5:00 PM - 6:00 PM

Purpose: Despite Spain's national plan for childhood obesity reduction, its local implementation remains challenging. This study used a co-creation process with multisectoral stakeholders in Villa de Vallecas, a low-socioeconomic district of Madrid, to identify key barriers to implementation and collaboratively develop locally relevant solutions.

Methods: In fall 2025, as part of the Horizon Europe OBCT project, a participatory co-creation process was conducted, guided by the PRODUCES+ framework and the Participatory and Appreciative Action and Reflection approach. An alliance was established with *Madrid Salud*, the city's on-the-ground public health institution, to facilitate community engagement and participant recruitment through existing relationships and continual follow-up. Ten participants representing public health, healthcare, sports, social services, community organisations, national government, and research took part in four workshops. The first two workshops focused on identifying implementation barriers and generating solutions through iterative discussions that encouraged reflection and consensus-building. In the first session, participants applied the social determinants of health and socio-ecological frameworks to identify structural

SYMPOSIUM

drivers of childhood obesity. Building on this theoretical grounding, they engaged in a collaborative brainstorming exercise to identify key implementation barriers affecting childhood obesity prevention in their district. The second session linked each barrier to potential solutions through group dialogue and collective agreement. Participant reflections were captured through brief evaluation surveys and researcher debriefing notes collected after each session. Workshop materials and notes were synthesised thematically.

Results: Participants collaboratively identified five key barriers to local implementation: low awareness of childhood obesity, limited interdepartmental coordination, poor visibility of community resources, unstable human and financial resources, and insufficient understanding of families' needs. Five corresponding solutions were co-developed, leading to the creation of concrete tools to address these barriers. Participants also reported increased empowerment, strengthened interdepartmental relationships, and a renewed sense of shared purpose in tackling childhood obesity locally.

Conclusion: This co-creation process demonstrated the value of participatory and intersectoral collaboration by identifying five context-specific implementation key barriers and developing the five corresponding community-informed solutions. Beyond tangible outputs, the process fostered professional empowerment and collective ownership, both key elements for advancing sustainable childhood obesity prevention.

S.2.39-2

Selecting Implementation Strategies and Tools through Co-creation Workshops in Low-socioeconomic Municipalities in Poland: Results from the OBCT Project

A. Banik¹, M. Siwa¹, N. Paduszynska¹, A. Luszczynska¹

¹SWPS University, Wrocław, Poland

S.2.39 Motivation and behavior change: Co-creating a toolbox to improve the implementation of childhood obesity prevention policies in low socioeconomic municipalities – the OBCT Project

Room 5, May 29, 2026, 5:00 PM - 6:00 PM

Purpose: To present the results of co-creation workshops conducted in Polish municipality with low socioeconomic position, focusing on the implementation strategies and tools prioritized by local stakeholders for inclusion in the policy implementation toolbox to prevent childhood obesity.

Methods: As part of the Horizon Europe OBCT project, local co-creation workshops were held in June 2025 with representatives from schools, health sector, local authorities, NGOs, and community organizations. Participants discussed, adapted, and voted on proposed implementation strategies and tools across seven thematic goals related to the prevention of childhood obesity (e.g., diagnosis, planning, collaboration, community engagement). Voting results were analyzed using predefined decision thresholds ($\geq 30\%$ votes for high priority; 20–29% for medium priority) to identify the most supported items.

Results: Across seven goals, participants expressed the strongest support for strategies promoting integration of health actions into standard institutional practice (46%), conducting local needs diagnosis (39%), and building intersectoral implementation teams (39%). Among tools, the most highly rated included the annual health action plan template (40%), local health diagnosis questionnaire (36%), and set of best-practice cards (36%). The highest overall engagement was observed for strategies and tools related to community and family involvement, including storytelling-based communication and social media micro-campaign templates.

Conclusion: The co-creation process revealed that Polish stakeholders prioritize sustainability, intersectoral collaboration, and community engagement as key drivers for effective policy implementation. The identified strategies and tools provide practical, context-specific guidance for integrating obesity prevention policies into local systems, supporting the development of the cross-country OBCT implementation toolbox.

S.2.39-3**European Policy Implementation Toolbox to Prevent Childhood Obesity: A Cross-country Co-creation Process**N. Lien¹, S.H. Herstad¹, B. Meshkovska¹¹University of Oslo, Department of Nutrition, Oslo, Norway**S.2.39 Motivation and behavior change: Co-creating a toolbox to improve the implementation of childhood obesity prevention policies in low socioeconomic municipalities – the OBCT Project****Room 5, May 29, 2026, 5:00 PM - 6:00 PM**

Purpose: The objective of this study is to integrate theoretical insights with co-creation experiences across Poland, Spain and Norway in order to develop a policy implementation toolbox designed for European contexts. This European toolbox aims to serve as a comprehensive roadmap for local governments, facilitating the implementation of national childhood obesity prevention policies.

Methods: The process of co-creating country-specific toolboxes involved collaboration with local governments in Poland, Spain and Norway during the summer and fall of 2025. Building on these country-based toolboxes, the OBCT project teams from Poland, Spain, Norway and Denmark convened for a two-day workshop in September 2025. The workshop focused on establishing: (1) the overarching goals of the European toolbox, and (2) the specific subtasks necessary to achieve these goals. This process was informed by theory and expert knowledge across multiple disciplines, including nutrition, physical activity, psychology, public policy, and implementation science. Following the workshop, the project teams engaged in collaborative work over the subsequent month to develop a manual detailing a structured roadmap for local governments to implement national childhood obesity prevention policies, featuring clearly defined goals, subtasks, procedural steps, and templates.

Results: The European toolbox delineates five primary goals: (1) Raising Awareness: Promoting a whole of society approach to obesity prevention; (2) Building Lasting Partnerships: Establishing intersectoral partnerships that facilitate coordinated local actions for childhood obesity prevention; (3) Mapping Community Assets: Participatory mapping of assets to inform and strengthen local obesity prevention efforts; (4) Prioritization of a Policy Mix and Action Selection: Developing a coherent policy mix and collaboratively selecting and adapting actions aimed at obesity prevention, with active community and target group participation; (5) Ensuring Continuity and Sustainability: Embedding the selected policy mix and actions within local government structures and routine practices.

Conclusion: A key conclusion of this study is the necessity for local governments to adopt an intersectoral approach to enhance their understanding and application of a whole-of-society approach for obesity prevention. Throughout all stages of the process, it remains critical to involve the target population (persons living with obesity, children, parents, families) to ensure the effectiveness and relevance of implemented actions.

S.2.40-1**Oheró:kon: Revitalizing Rites of Passage for Haudenosaunee Youth and Community Wellbeing**A.M McComber¹, J. Beauvais², J. Shenandoah²¹McGill University, Department Of Family Medicine, Montreal, Canada, ²Akwesasne Mohawk Nation, Hogansburg, United States**S.2.40 Indigenizing Wellbeing Research: Relational Pathways to Wellbeing: Revitalizing Indigenous Mentorship, Rites of Passage, and Community Health Promotion****Room 6, May 29, 2026, 5:00 PM - 6:00 PM**

Purpose: Haudenosaunee communities are revitalizing rites of passage teachings to support youth in their journeys of self-discovery within a contemporary context shaped by the enduring impacts of colonization. These “coming of age” experiences—known as *Oheró:kon*—reaffirm traditional pathways of growth and responsibility, nurturing physical, mental, emotional, and spiritual wellbeing. The re-emergence of these land-based practices represents both a cultural resurgence and an assertion of self-determination, strengthening community identity and collective wellness.

Methods: This study draws on the lived experiences of two Haudenosaunee knowledge keepers who have guided and

SYMPOSIUM

participated in *Oheró:kon* through community- and family-organized teachings, ceremonies, and land-based activities. Using narrative inquiry grounded in Indigenous methodologies, the knowledge keepers share personal stories that illuminate the year-long mentorship and teaching process. Adults in the program assume the roles of aunts and uncles to the youth, establishing relationships grounded in peace, the good mind, personal responsibility, and love. These relational and land-based practices foster confidence, respect, and cultural belonging among participants. The narratives were collaboratively interpreted through guided reflection and discussion, following Haudenosaunee principles of relational accountability and consensus-based meaning-making. Story analysis focused on identifying recurring teachings, metaphors, and experiences that illustrated processes of transformation, relationship-building, and balance with the natural world.

Results: The *Oheró:kon* journey functions as a transformative, intergenerational education process that unites participants in mutual learning and growth. Through ceremony, food practices, and physical activity, youth develop new frameworks for understanding themselves and their roles within family, community, and the natural world. The approach dissolves generational barriers, strengthens cultural identity, and restores balance between humans and the land.

Conclusion: Revitalized rites of passage rooted in Haudenosaunee teachings cultivate youth leadership, resilience, and wellbeing while reinforcing intergenerational knowledge transmission and cultural continuity. Centering youth in culturally grounded, land-based learning not only promotes individual health and identity but also sustains the collective wellness and vitality of Haudenosaunee society.

S.2.40-2

Centering Māori Knowledge for Youth Wellbeing

R. Hogg¹, T. Hogg²

¹AUT University, School of Sport, Exercise and Health, Auckland, New Zealand, ²Youth Community Member, Auckland, New Zealand

S.2.40 Indigenizing Wellbeing Research: Relational Pathways to Wellbeing: Revitalizing Indigenous Mentorship, Rites of Passage, and Community Health Promotion

Room 6, May 29, 2026, 5:00 PM - 6:00 PM

Purpose: This study centers Mātauranga (Māori knowledge) in the context of physical activity. The research question is: How can Mātauranga be used to engage Rangatahi (Māori youth) in Physical Activity for Waiora (holistic wellbeing)? By centering Mātauranga as the dominant knowledge system, we are able to explore and showcase indigenous ways of knowing and being. Whilst Mātauranga is an ancient knowledge system, Mātauranga is constantly adapting to this contemporary world within the context of physical activity.

Methods: Kaupapa Māori Research is the chosen methodology. Kaupapa Māori Research is research that is determined by Māori, for Māori, with Māori, and in a Māori way [1]. The methods for this study are Wānanga and Pūrākau. Wānanga is a gathering of people governed by tikanga (Māori protocols). The aim of wānanga is to compose knowledge with a chorus of intention, participants engage in active and collective discussion and problem solving. Wānanga is also a place where the transmission of intergenerational knowledge occurs between a tuakana (mentor) and teina (mentee) [2]. When deconstructing the word pūrākau; pū are the roots of a tree, embedded deep within Papatūānuku (Earth mother), in a place of darkness, the place of the unseen. Pū represents deep, grounded, implicit knowledge. Rākau is a tree, situated above the ground in the realm of Ranginui (Sky father), in the place of light, the place of the seen. Rākau represents the visible, the explicit knowledge. Bolton describes pūrākau as a reflective practice by “paying critical attention to the practical values and theories which inform everyday actions, by examining practice reflectively and reflexively” [3]. For the symposium, we; an Academic (mentor) and a Rangatahi (mentee) will jointly unpack the concepts that underpin the methodology and methods of this study.

Results: Mātauranga is deeply rooted in a geographical place through pūrākau, emphasising the importance of knowing place to then authentically engage in physical activity. Establishing a physical activity framework occurs in a structured and planned way through wānanga.

Conclusion: This study contributes both conceptually and methodologically to physical activity research. Advancing Indigenous research methodologies and methods has the ability to enhance and transform the field of physical activity.

S.2.40-3**Transformational Mentorship: A Relational Journey in Indigenous Health Promotion****C. Hare¹, A. McComber²**¹Queen's University, School of Kinesiology and Health Studies, Kingston, Canada, ²McGill University, Department of Family Medicine, Montreal, Canada**S.2.40 Indigenizing Wellbeing Research: Relational Pathways to Wellbeing: Revitalizing Indigenous Mentorship, Rites of Passage, and Community Health Promotion****Room 6, May 29, 2026, 5:00 PM - 6:00 PM****Purpose:**

Mentorship is an essential form of knowledge transfer within Indigenous contexts, where learning occurs through relational processes grounded in reciprocity and shared responsibility. In contrast, Western academic mentorship structures often emphasize hierarchy and overlook the wholistic dimensions of the learner that nurture personal development and wellbeing. This work explores how Indigenous mentorship functions as a relational process of knowledge transfer that strengthens engagement in Indigenous community health research.

Methods:

This work employs Indigenous storytelling within an autoethnographic, community based framework to describe a three year mentorship journey between a Haudenosaunee mentor and a Métis youth in an Indigenous health promotion project. The project supports the sharing of a Kanien'keha:ka community mobilization model through workshops, training sessions, and community partnerships. Narrative and thematic analysis was conducted collaboratively, guided by Indigenous epistemological principles of relational accountability and respect for story as both method and meaning. Key moments of transformation were explored through reflexive dialogue to ensure interpretations remained culturally grounded and relationally coherent.

Results:

Our mentorship evolved into a deeply personal and transformative journey that extended beyond academic boundaries into friendship, family, and community. It created space for critical reflection during moments of uncertainty in the project's direction and success. By keeping cultural values at the forefront, even disagreements became opportunities for deep dialogue and self reflection. Our shared experiences, from moments of chaos to laughter, revealed that mentorship grounded in Indigenous teachings supports both learners and mentors to grow resilient and thrive. Haudenosaunee and Métis cultural grounding created a mutually reinforcing cycle of growth, where emotional awareness and cultural understanding became central to personal development and our ability to advance health promotion in Indigenous community contexts.

Conclusion:

Indigenous mentorship models grounded in cultural values foster resilient and adaptive ways of learning that extend beyond traditional academic structures. Our experience demonstrates that mentorship rooted in relationship and reciprocity not only supports personal growth but also strengthens the capacity to engage in community research and health promotion in Indigenous contexts. This approach offers valuable insights for reimagining mentorship and personal development within Indigenous health promotion and broader community based participatory research.

S.2.41-1**Evaluating the Impact of a Redesigned School Playground on Children's Play, Preferences, and Wellbeing: Insights from an International Comparative Study****C. Pawlowski¹, I. Lousen¹, A. Johnstone², P. McCrorie³, J. Schipperijn¹**¹University of Southern Denmark, World Playground Research Institute, Active Living Research Unit, Department of Sports Science and Clinical Biomechanics, Odense, Denmark, ²University of Glasgow, General Practice and Primary Care, Glasgow, United Kingdom, ³University of Exeter, Department of Public Health and Sports Science, Exeter, United Kingdom**S.2.41 Children and families: Taking Risks in Play: Rethinking School Environments for Children's Physical Activity and Wellbeing****Room 7, May 29, 2026, 5:00 PM - 6:00 PM**

SYMPOSIUM

Purpose: School playgrounds are key settings for promoting children's physical activity, providing opportunities for active play, social interaction, and creativity during the school day. This study evaluated the impact of a newly installed manufactured playground on children's play behaviour, preferences, and social and emotional wellbeing. Bringing together data from Denmark and Scotland, it offers a novel cross-country comparison of how school environments shape active play and wellbeing.

Methods: A pre-post design was implemented across six primary schools in Denmark and Scotland to examine changes following the introduction of redesigned playgrounds. All children in participating schools were eligible to take part. Baseline data were collected between October 2023 and September 2024, with follow-up conducted one year later. Consenting children completed the Loneliness and Social Dissatisfaction Scale to evaluate social and emotional wellbeing, and the *Lunchtime Enjoyment of Activity and Play (LEAP)* Questionnaire to assess playground preferences. The System for Observing Outdoor Play Environments in Neighborhood Schools (SOOPEN) was used at follow-up to observe play type, activity level, and social context. Descriptive and regression analyses will compare baseline and follow-up data to assess changes in preferences and wellbeing. Observational data are being coded to examine how physical activity, play type, and social interaction vary across playground zones.

Results: A total of 942 children aged 5–12 years completed baseline and follow-up assessments, which are currently under analysis. While preliminary findings indicate some positive trends, there was no significant effect on the Children's Loneliness and Social Dissatisfaction Scale. However, LEAP questionnaire data revealed that more children reported being happy with using play structures in the redesigned playground compared to the old playground. SOOPEN observations showed no difference in the number of children playing alone or in levels of conflict between the redesigned and original playgrounds.

Conclusion: This study provides new insights into how playground design influences children's physical activity and wellbeing across cultural settings. Findings will inform evidence-based strategies for developing school environments that balance safety with managed risk, promoting movement, creativity, and emotional health in diverse contexts.

S.2.41-2

How Does the Outdoor Play and Learning (OPAL) Programme Affect Children's Play Activities, Adventurous Play and Enjoyment of Playtimes: Evidence from Two Case Study Schools

H. Dodd¹, R. Nesbit², B. Longdon¹, B. Oliver³, L. FitzGibbon⁴

¹University of Exeter, Public Health and Sport Sciences, Exeter Medical School, Exeter, United Kingdom, ²University of Exeter, Department of Psychology, Exeter, United Kingdom, ³University of Reading, Reading, United Kingdom, ⁴University of Stirling, Stirling, United Kingdom

S.2.41 Children and families: Taking Risks in Play: Rethinking School Environments for Children's Physical Activity and Wellbeing

Room 7, May 29, 2026, 5:00 PM - 6:00 PM

Purpose: School playtimes provide opportunity for children to engage in active, adventurous play but many schools have policies that act as barriers to this type of play. The Outdoor Play and Learning (OPAL) programme takes a whole-school approach to improve play in schools, including improving diversity of play experience and adventurous play. The purpose of this study was to examine the impact of OPAL on children's play activities, adventurous play and enjoyment of playtime.

Methods: Data were collected at two schools before and after implementation of OPAL (~12 months). We conducted scan observations at playground-level, and focal observations of individual child play during regular playtimes at school. Children aged 7-10 years completed questionnaire measures of their emotions during playtime. All measures were taken from the Multi-dimensional Toolkit for the Assessment of Play in Schools (M-TAPS). Initial analyses used t-tests to examine changes from pre to post on the focal observation data and the questionnaire data.

Results: For schools 1 (S1) and 2 (S2), the scan observation descriptive results showed an increase in the number of children engaged in: play (S1: 84%-95%; S2: 91%-94%); nature play (S1: 3%-4%; S2: 2%-7%); loose parts play (S1: 8%-19%; S2: 0%-7%); and adventurous play (S1: 11%-17%; S2: 16%-22%). These findings were supported by focal observations at both schools which showed a significant increase in adventurous play, (S1: 3%-8%; S2: 10%-17%, $p < .05$), and loose parts play, (S1: 1%-11%; S2: 0%-8%, $p < .05$). Child report showed a significant decrease in negative affect after OPAL at S1, $t(70.53) = 4.24, p < .001, d = -0.89$; but this effect was not significant for S2, $t(310.40) = 1.84, p = 0.07, d = -0.21$.

Conclusion: These two case studies demonstrate that the OPAL programme can increase adventurous, nature and

loose parts play during primary school playtimes. These types of play offer broad benefits to children's physical and emotional development.

S.2.41-3

Parents Perceptions of Independent and Risky Play in Schools: Findings from the British Children's Play Survey

R. Nesbit¹, L. FitzGibbon², H. Dodd³

¹University of Exeter, Psychology, Exeter, United Kingdom, ²University of Stirling, Psychology, Stirling, United Kingdom,

³University of Exeter, Public Health and Sport Sciences, Exeter, United Kingdom

S.2.41 Children and families: Taking Risks in Play: Rethinking School Environments for Children's Physical Activity and Wellbeing

Room 7, May 29, 2026, 5:00 PM - 6:00 PM

Purpose: Play in schools provides opportunities for children to engage in independent, outdoor, and risky play, supporting their health, behaviour, and development. Despite this, schools often report that parental safety concerns limit such opportunities. However, limited quantitative evidence exists on parents' actual beliefs about play in school settings. Using data from the British Children's Play Survey, this study aimed to characterise parents' perceptions of play in schools and examine the extent to which these perceptions are explained by socio-demographic and geographic factors, as well as parents' attitudes towards risk in play and protection from injury.

Methods: Data were drawn from the British Children's Play Survey, a nationally representative sample of 1,919 parents (54% female) of children aged 5–11 years living in Britain. Parents completed measures assessing perceptions of the importance of school playtime, attitudes towards outdoor play spaces, beliefs about appropriate levels of independence and risk, and attitudes towards engagement with risk and protection from injury. Ordinal regression models examined whether socio-demographic, geographic, and attitudinal factors explained variability in parents' beliefs.

Results: Overall, parents expressed strong support for school playtime and the provision of outdoor play space, viewing it as a vital part of the school day. Most parents endorsed the value of independence and some level of risk during play. However, 16% felt no risk was acceptable, while 22% were highly supportive of risky play. Variability in beliefs was partly explained by socio-demographic and attitudinal factors: parents who were younger, male, from minority ethnic groups, had a disability, or lower education levels were less supportive of risk and play in schools.

Conclusion: Findings indicate that, contrary to schools' perceptions, most parents value children's independent and risky play. Schools can therefore be reassured about parental support for enriching play environments. However, interventions promoting risky play should include parent-focused components to address lingering concerns, particularly among groups less supportive of risk. Risk-reframing approaches and the engagement of supportive "parent champions" may enhance communication and help schools implement balanced, developmentally beneficial play policies.

S.2.43-1

Use of Nutrition Incentives to Promote Diet Quality among Families Participating in the Supplemental Nutrition Assistance Program (SNAP): A Case Study from the United States

M. Vadiveloo¹, A. Tovar²

¹University of Rhode Island, Kingston, United States, ²Brown University, Social and Behavioral Sciences, Providence, United States

S.2.43 Policies and environments: Contrasting Approaches to Food and Nutrition Security: Targeted Nutrition Incentives vs. Universal Food Aid Reform

Room 9, May 29, 2026, 5:00 PM - 6:00 PM

Purpose: Anticipated changes to the US the social safety net are likely to adversely impact low-income families, making it relevant to consider what improvements could improve diet-related health outcomes. In 2024, RI implemented

SYMPOSIUM

the first statewide nutrition incentive program providing \$0.50 for every \$1 worth of fresh produce purchased at participating retailers. The What's on Your Plate (WOYP) and WOYP-Kids studies have longitudinally compared changes in fruit and vegetable (FV) consumption among participants over the short (6-8 mo) and longer (~1 year) term. Drawing on a body of research from this evaluation, this presentation will discuss the pros and cons of targeted programs like FV incentives to address food and nutrition insecurity, considering factors such as effectiveness (i.e., ability to improve diet quality and reduce food/nutrition insecurity) and sustainability (i.e., cost of the program and long-term funding models).

Methods: WOYP and WOYP-kids are mixed methods longitudinal pre-post studies among 725 adults (364 in Rhode Island and 361 in Connecticut) with complete data from online surveys at baseline and follow-up 1. Difference-in-difference analysis evaluated changes in FV intake between Rhode Island (intervention) and Connecticut (comparison). Implementation data was collected via in-depth interviews with implementation partners and advocates and via de-identified purchasing records from all participating households.

Results: Short-term, there was a non-significant increase in FV intake, that was only significantly greater among adults with higher baseline FV intake. No changes were observed in self-reported food and nutrition insecurity. Among children, FV frequency remained unchanged. Qualitative interviews revealed some challenges with coordinated implementation, limited community involvement, and poor program awareness and participation. Open-ended responses that queried participant's experiences following the termination of emergency allotments (loss of ~\$95/mo) revealed a rapid unraveling of food security, material hardship, and a deep sense of instability.

Conclusion: The WOYP and WOYP-Kids revealed limited effectiveness of FV incentives. While this may be reason to consider alternative approaches to improve nutrition security, other contextual factors may have contributed to the modest findings including low utilization, loss of emergency allotments and other social programs, and insufficient total SNAP incentives.

S.2.43-2

Evaluating the Nutritional Adequacy of Food Aid through a Multidimensional Lens

E. Carrillo-Alvarez¹, J. Muñoz-Martínez¹, M.J. La Rota-Aguilera², A. Rizo-Barroso², A. Moragues-Faus²

¹Universitat Ramon Llull. Blanquerna School of Health Sciences., Global Research on Wellbeing (GRoW) Research Group, Barcelona, Spain, ²University of Barcelona, Department of Economic History, Institutions, Politics and World Economy, Barcelona, Spain

S.2.43 Policies and environments: Contrasting Approaches to Food and Nutrition Security: Targeted Nutrition Incentives vs. Universal Food Aid Reform
Room 9, May 29, 2026, 5:00 PM - 6:00 PM

Purpose: This study assesses the impact of a public-community food aid program in Barcelona using a multidimensional framework of food insecurity. The research is part of the FOOD4GOOD project, which aims to understand food insecurity through a systemic, rights-based, and person-centered lens. This contribution presents findings for three of the six dimensions defined by the HLPE framework—availability, economic access, and utilization—based on an analysis of the food distributed through the program. By operationalizing specific indicators, the study offers an innovative approach to evaluating the quality, accessibility, and nutritional contribution of food aid interventions.

Methods: FOOD4GOOD employs a mixed-methods design. For the analysis of availability, economic access, and utilization, a descriptive quantitative approach was used, drawing on data collected during the last quarter of 2024. The study examined food parcels and prepared meals distributed across three sites, focusing on four indicators: the quantity and diversity of foods offered measured through the Global Dietary Recommendation Index and the degree of processing through the NOVA classification (availability), the economic savings they represent compared to the monthly cost of a healthy diet (economic access), and the nutritional adequacy based on dietary reference intakes (utilization). Nutritional analysis and food categorization were conducted to assess alignment with dietary guidelines and overall food quality.

Results: Food parcels scored between 8-15 out of 17 on GDRI, indicating a medium-to-high alignment with healthy eating guidelines. The average NOVA 1/4 ratio was 0.52, reflecting a significant presence of ultra-processed foods in some distributions. Estimated economic savings ranged from 17-115% of the monthly cost of a healthy diet, with parcels offering greater value than prepared meals. Nutritional analysis showed energy coverage ranging from 73-178% of DRI, with adequate levels of iron, vitamins A, C, and B12, but recurring deficits in calcium, vitamin D, and protein.

Conclusion: Applying a multidimensional framework enables a more precise evaluation of food aid effectiveness. The findings show efforts to improve the availability, economic access, and utilization of healthy foods, though challenges remain regarding nutritional quality and food processing. This evidence provides concrete tools for designing public policies that promote more dignified, sustainable, and rights-based approaches to food assistance.

S.2.44-2

Navigating Multi-country, Multi-disciplinary Co-design with Families, Adolescents and Healthcare Practitioners: The SmartCHANGE Project

C. Dictus¹, T. Altenburg¹, M. Hoogsteder¹

¹Amsterdam University Medical Centers, Public and Occupational Health, Amsterdam, Netherlands

S.2.44 E- & mHealth: The latest insights in the development and implementation of e-health applications for health promotion in children and adolescents – the SmartCHANGE project,
Multipurpose Room, May 29, 2026, 5:00 PM - 6:00 PM

Purpose: The SmartCHANGE project aims to improve lifestyle behaviors among children and adolescents, as for instance only 19% of European 11-17 meet physical activity requirements. E- and m-health interventions present a promising solution, though existing interventions are often insufficiently tailored to the needs of these end-user groups. This study evaluates facilitators' experiences in applying a co-design approach aimed at developing solutions to improve children and adolescents' lifestyle behaviors, in collaboration with three different stakeholder groups in four different countries.

Methods: The co-design protocol included a theoretical framework, a table summarizing actionable goals and suggested activities to achieve them, a timeline comparing suggested session number per stakeholder group with design deadlines, and a practical protocol describing potential sessions. This protocol was applied in an adaptive and flexible manner at each study site to fit local needs, resulting in a different number of sessions and different activities at each site. Facilitators completed detailed log books and reflection forms. Two researchers and one designer worked through the logbooks of all study sites to identify challenges and best practices. These were discussed in two alignment meetings, after which a member-check was conducted with the facilitators at each study site.

Results: Challenges were specific to local study sites and centered primarily on recruitment and motivation, for instance fitting the sessions into the busy schedules of healthcare practitioners and engaging families in Portugal in particular. Other challenges included the need to both tailor the process to local needs and produce results for designers to create unified solutions. Numerous best practices were also identified in three areas: adaptability (e.g. Choosing the time and space to suit participants); session structure (e.g. including warm-ups and relaxation); and engagement (e.g. Aligning with participant interests where possible).

Conclusion: Through the flexible co-design approach we were able to identify key factors of importance to each of our stakeholder groups. However, contextual differences are significant and present a challenge to efforts at producing cross-border solutions. Future studies may consider more layered approaches that begin with a more open-ended approach to the format and focus of interventions.

S.2.44-1

SmartCHANGE Methodology: Developing mHealth Applications

G. Jurak¹, T. Altenburg², T. Tammelin³, J. Ribeiro⁴, C. Dictus², M. Sorić^{1,5}

¹University of Ljubljana, Faculty of Sport, Ljubljana, Slovenia, ²VUmc, Amsterdam Public Health research institute, Amsterdam, Netherlands, ³Jamk University of Applied Sciences, Jyväskylä, Finland, ⁴University of Porto, Faculty of Sport, Research Centre in Physical Activity Health and Leisure, Porto, Portugal, ⁵University of Zagreb, Faculty of Kinesiology, Zagreb, Croatia

S.2.44 E- & mHealth: The latest insights in the development and implementation of e-health applications for health promotion in children and adolescents – the SmartCHANGE project,
Multipurpose Room, May 29, 2026, 5:00 PM - 6:00 PM

Purpose: The purpose of the SmartCHANGE project is to develop and validate innovative, personalized e- and mHealth solutions for Non-Communicable Disease (NCD) risk prediction and prevention. This research addresses

SYMPOSIUM

the challenge of integrating complex, multi-domain lifespan data (lifestyle, physical fitness, biomarkers) for accurate NCD risk prediction while strictly safeguarding data privacy. The innovation lies in the early age risk prediction, and creation of unified, Trustworthy and Explainable Artificial Intelligence (XAI) risk models using Federated Learning (FL).

Methods: This is a proof-of-concept study using Participatory Design within an agile methodology to create the solutions: healthcare professional (HCP) web app and citizen HappyPlant mobile app with fitness trackers. Unified NCD risk-prediction models are built using Deep Neural Networks trained on 10 harmonized datasets (around 5 million subjects). FL is employed to train models on sensitive local data, ensuring privacy. XAI via counterfactual explanations translates complex risks into actionable insights. The feasibility and efficacy are tested in a non-randomized trial design with a control group (clustered at the HCP level) involving approximately 30 HCPs and 500 participants (250 adolescents, 250 children/parents) across five real-world sites in Europe and Taiwan, assessing global transferability. Continuous compliance with legal and ethical requirements (GDPR, Medical Device framework, AI Act) is ensured throughout the project phases.

Results: The primary results will focus on demonstrating the feasibility, usability, and preliminary efficacy of the SmartCHANGE tools. The analysis will yield: Validation metrics for the FL-trained deep neural network risk models (predictive accuracy and XAI effectiveness), and process results from the Participatory Design. Furthermore, findings from the non-randomized trial will assess uptake, compliance, and preliminary impact on behavioral physical activity metrics and changes in risk factors, comparing intervention and control groups.

Conclusion: The SmartCHANGE project offers a significant contribution to behavioral nutrition and physical activity practice by introducing a scalable, privacy-preserving (FL) and trustworthy (XAI) mHealth system for personalized NCD prevention. Its holistic approach and integration of next-generation AI have the significance of setting a new standard for effective, globally transferable digital health interventions.

S.2.44-3

Feasibility and Usability of AI-based e-and m-Health Tools to Support Healthy Behaviours in Children & Adolescents: Preliminary Findings from SmartCHANGE Study in Diverse European Settings

J. Ribeiro¹, M. Santos¹, G. Jurak², T. Tammelin³, T. Altenburg⁴, C. Dictus⁴, M. Sorić⁵

¹University of Porto / Faculty of Sport, Research Centre in Physical Activity Health and Leisure / Laboratory for Integrative and Translational Research in Population Health (ITR), Porto, Portugal, ²University of Ljubljana / Faculty of Sport, Ljubljana, Slovenia, ³Jamk University of Applied Sciences, Jyväskylä, Finland, ⁴VUmc | Amsterdam Public Health Research Institute | Amsterdam UMC, Child & Adolescent Public Health Research & Innovation (CAPRI) | Department of Public and Occupational Health, Amsterdam, Netherlands, ⁵University of Ljubljana / Faculty of Sport, Laboratory for Physical and Motor Development Diagnosis, Ljubljana, Slovenia

S.2.44 E- & mHealth: The latest insights in the development and implementation of e-health applications for health promotion in children and adolescents – the SmartCHANGE project,
Multipurpose Room, May 29, 2026, 5:00 PM - 6:00 PM

Purpose: The **SmartCHANGE project** aims to promote healthy lifestyles and reduce the long-term risk of non-communicable diseases in youth by integrating artificial intelligence (AI) into e- and m-health interventions. This study assessed the **feasibility and usability** of the SmartCHANGE tools, the **Web App** for healthcare professionals (HCPs) and the **HappyPlant Mobile App** for children, adolescents, and families across four culturally distinct European contexts: Portugal, the Netherlands, Finland, and Slovenia.

Methods: A non-randomised feasibility design was implemented in Portugal, the Netherlands, Finland, and Slovenia. Participants included approximately 400–500 children/adolescents (6–14 years) and 25–35 HCPs. The Web App supports HCPs in AI-driven risk identification, behavioural goal-setting, and progress monitoring. It was designed to integrate AI-driven risk estimation with clinical decision support for health promotion. It aggregates lifestyle, biometric, and behavioural data, including physical activity, sleep, and diet, collected from the mobile app and wearable devices. Using explainable AI algorithms, it generates personalised risk scores for metabolic and cardiovascular diseases and visually displays the relative contribution of key behavioural factors (e.g., low physical activity, inadequate sleep). The HappyPlant App utilises gamification and family engagement to promote improvements in physical activity, diet, sleep, and screen time. Feasibility outcomes included recruitment, adherence, and integration into existing care workflows; usability was assessed through user surveys and focus groups.

Results: Initial feedback from participants suggests acceptability across all sites. Families reported strong motivation through gamified elements and personalised goals. HCPs valued the clarity and structure of the Web App but

highlighted the importance of tailored training to integrate AI outputs into counselling. Cross-country implementation was achieved through minor cultural and linguistic adaptations, particularly in relation to physical activity types and contexts.

Conclusion: The SmartCHANGE digital tools demonstrate promising feasibility and usability in diverse European settings, supporting the integration of **AI-assisted, behaviourally informed e- and m-health solutions** in preventive youth healthcare.

Measuring Interpersonal Determinants of Adolescents' Physical Activity Behaviors in Digital and Social Media: The INDEEP Project

K.L. Quevedo¹, S. Toosinezhad², L. Martens¹, L. Christianson³, A. Hebestreit¹

¹Leibniz Institute for Prevention Research and Epidemiology – BIPS, Epidemiological Methods and Etiological Research, Bremen, Germany, ²University of Limerick, Limerick, Ireland, ³Leibniz Institute for Prevention Research and Epidemiology – BIPS, Administration, Bremen, Germany

S.3.45 Children and families: Building on a decade of evidence with the INDEEP project: Standard Instruments for measuring physical activity behaviours and their determinants in European youth

Auditorium, May 30, 2026, 8:00 AM - 9:00 AM

Purpose: To develop and test an instrument for assessing interpersonal determinants of adolescent physical activity (PA) in digital and social media.

Methods: A scoping review was conducted following international guidelines (<https://osf.io/9uqvz/files/d54uv>). Eligible studies included healthy adolescents (10-19 years old) examining interpersonal determinants of PA within digital or social media contexts. Four databases and grey literature sources were searched without restrictions, and data were charted and synthesized descriptively by independent reviewers. The most frequently associated determinants were considered for developing the instrument.

Results: Of 6744 screened records, 22 studies (2009-2024) met the inclusion criteria spanning Europe, North America, Latin America, Asia, and Australia. Digital channels included social media (n=13), digital apps (n=9), messaging (n=7), websites (n=5), and video chat (n=1). PA was either self-reported (n=8), device-measured (n=7), both (n=5), or reported as PA intentions (n=2).

Social support, through in-app interactions (e.g., likes, comments), direct encouragement (e.g., reminders, motivational messages), or joint participation, was the most frequently assessed and positively associated determinant (n=20). Social norms (n=9), social comparison or competition (n=8), role modeling (n=7), social interaction (n=6), data sharing (n=4), and parasocial relatedness with influencers or peers (n=3) were less frequently assessed, often included as implicit behaviors rather than standalone constructs.

Determinants were measured through self-report questionnaires or platform behavior tracking, using heterogeneous, often unvalidated instruments, and inconsistent operational definitions across studies. The results aligned with the Social Cognitive Theory constructs, and most frequently assessed determinants were integrated for a self-administered questionnaire for adolescents. The instrument incorporates 5 items on social support (parental, peer, siblings, and teacher support), 4 on role modelling (parents, friends), 6 on social norms (perceived prevalence, importance, and acceptance of PA), and 2 on digital platform use and social influence on PA.

Conclusion: The newly developed instrument is part of the examination battery in the EU-funded INDEEP project (<https://www.indeep-project.eu/>). The ultimate aim of the INDEEP project is the provision of standardized instruments and operating procedures measuring intra- and interpersonal, biological, social, environmental, and policy factors influencing PA in adolescents. The instruments are being piloted in early 2026, with results expected in time for the congress presentation.

SYMPOSIUM

S.3.45-2

Understanding the Contexts of Adolescents' Physical Activity across Europe: Insights from the INDEEP Project

M. Kastrinou¹, S. Compennolle¹, B. Chaix², L. Cardoso da Silva, D. Van Dyck¹

¹Ghent University, Department of Movement and Sports Sciences, Ghent, Belgium, ²Institute National de la Santé et de la Recherche Médicale, INSERM, Paris, France

S.3.45 Children and families: Building on a decade of evidence with the INDEEP project: Standard Instruments for measuring physical activity behaviours and their determinants in European youth

Auditorium, May 30, 2026, 8:00 AM - 9:00 AM

Purpose: To conduct a systematic review synthesizing studies that use Global Positioning System (GPS), Geographic Information System (GIS), and accelerometry to identify the physical contexts in which adolescents are physically active. Additionally, to design a geo-based Ecological Momentary Assessment (EMA) study to examine these contexts in real life, drawing on findings from the review and complementary evidence.

Methods: A systematic review was conducted following international standards and registered in PROSPERO to identify studies combining GPS, GIS, and accelerometry to objectively assess locations of physical activity (PA) among adolescents. Study screening and quality appraisal were performed using standardized tools, and results were synthesized narratively due to methodological heterogeneity. Based on the review findings, a multi-country study protocol was developed using the *Eco-Emo Tracker*, a smartphone application integrating GPS tracking with EMA surveys tailored to the locations where adolescents are active. Participants will use the app and wear two activity monitors (ActiGraph and SENS) for seven consecutive days. The protocol will be pilot tested in 300 adolescents (aged 12–14 years; 60 per country) from Belgium, the Netherlands, Norway, Portugal, and Germany in early 2026.

Results: Across 35 studies from 12 countries, school and home emerged as primary contributors to adolescents' moderate-to-vigorous PA, with additional activity observed in streets, greenspaces, and sports facilities. The geo-based EMA tool operationalizes these insights by providing an interactive interface that displays GPS-tracked routes linked with contextual information. Participants annotate their locations and trips each evening by answering *Where were you?*, *Were you alone or with others?*, and *What mode of transportation did you use?* Data from the app and activity monitors will be integrated to generate a dynamic representation of time, location, and levels of PA, providing a detailed overview of adolescents' PA behaviours shortly after they occur. At the conference, results from the systematic review and preliminary findings from the INDEEP pilot study will be presented.

Conclusion: Grounded in systematic review evidence, this geo-based EMA tool offers a novel, context-informed approach to understanding adolescent PA across Europe. The findings will inform adaptable, context-specific strategies to promote active lifestyles among adolescents.

S.3.45-3

Accelerometer-based Youth Physical Activity Measurement with Machine Learning: Systematic Review Findings, Validation Cohort Development, and Application to INDEEP

J. Ma¹, H. Coughlin^{2,3}, A. Donnelly^{2,3}, K. Dowd⁴, P. Van De Ven^{5,3}, E. Kolle⁶, B.H. Hansen¹

¹University of Agder, Department of Sport Science and Physical Education, Kristiansand, Norway, ²University of Limerick, Department of Physical Education and Sport Science, Limerick, Ireland, ³University of Limerick, Health Research Institute, Limerick, Ireland, ⁴Technological University of the Shannon, Department of Sport and Health Sciences, Athlone, Ireland, ⁵University of Limerick, Department of Electronic & Computer Engineering, Limerick, Ireland, ⁶Norwegian School of Sport Sciences, Department of Sports Medicine, Oslo, Norway

S.3.45 Children and families: Building on a decade of evidence with the INDEEP project: Standard Instruments for measuring physical activity behaviours and their determinants in European youth

Auditorium, May 30, 2026, 8:00 AM - 9:00 AM

Purpose: To identify opportunities and limitations in applying machine learning (ML) to accelerometer-based physical activity (PA) measurement among children and adolescents through a systematic review and to translate these insights into developing and validating algorithms on an independent, richly labelled cohort, which will be applied to

the INDEEP and general youth datasets.

Methods: A comprehensive literature search was conducted, targeting studies using supervised ML for accelerometer-based PA measurement in 5-19-year-old children and adolescents. Data extraction covered participant characteristics, accelerometer configurations, study settings, preprocessing approaches, ML architectures, validation strategies, and performance metrics. A validation protocol was designed based on the findings from the systematic review to address critical gaps.

Results: Among the 31 studies identified, most used structured protocols, and few had freelifing evaluations. Common accelerometer placements were hip/waist and wrist, and random forests and artificial neural networks were the predominant models. There were 3 to 10 classes in PA type and intensity classification algorithms, among which most accuracies exceeded 70%. For energy expenditure prediction algorithms, the root mean square error (RMSE) typically ranged from 1.2 to 2.0 METs. Few studies tested models on fully independent cohorts, highlighting generalisability gaps. To address these gaps, the planned validation will span structured, semistructured, and freelifing phases, thereby increasing ecological validity. The first two phases will be performed under indirect calorimetry and direct researcher observation for ground truth, while the freelifing phase will last one day with at least 10 hours of continuous downward-facing video for groundtruth labelling. In addition, the validation will be conducted in both Ireland and Norway to support external validation. The bestperforming model will then be applied to the INDEEP and potentially other youth accelerometry datasets to enable harmonised PA assessment at scale.

Conclusion: ML-based accelerometry in youth shows strong technical promise but remains limited by protocol heterogeneity and a lack of free-living validation. The subsequent validation study will address these gaps and provide accurate and transferable PA measurement, which aligns with INDEEP's mission to deliver harmonised, scalable, and context-sensitive European evidence to support frameworks and tools that help adolescents meet WHO PA recommendations.

S.3.46-1

How Park Characteristics and Urban Contexts Are Associated with Visitor Profiles and Activity Levels: Insights from Parks in Cuenca, an Andean City of Ecuador

M.J. Molina^{1,2}, S. Escandon², A. Ochoa², D. Van Dyck¹, B. Deforche^{3,4}

¹Ghent University, Department of Movement and Sports Sciences, Ghent, Belgium, ²University of Cuenca, Bioscience Department, Cuenca, Ecuador, ³Ghent University, Department of Public Health and Primary Care, Ghent, Belgium, ⁴Vrije Universiteit Brussel, Department of Movement and Sport Sciences, Brussel, Belgium

S.3.46 Policies and environments: Public green spaces as health-promoting environments across continents: integrating observational evidence, lived experiences and methodological innovation

Room 1, May 30, 2026, 8:00 AM - 9:00 AM

Purpose: Public parks play a vital role in promoting physical activity (PA), social interaction, and well-being, yet little is known about how park use varies across urban and peri-urban contexts in low- and middle-income countries (LMICs), where disparities in infrastructure and accessibility may shape health inequities. This study aimed (1) to describe park characteristics, the number of park users, visitor profiles, and park-based PA, and (2) to examine how time-related factors were associated with visitor numbers and activity levels, analyzed separately for urban and peri-urban parks.

Methods: A cross-sectional study was conducted in 20 parks in Cuenca. Urban parks (n = 12) were selected proportionally by size, and all peri-urban parks in Cuenca (n = 8) were included. Park characteristics were assessed using the EAPRS tool, and in a subsample of 10 parks (selected based on visitation and perceived safety), visitor profiles and PA levels were observed using SOPARC. Observations were conducted over seven consecutive days across morning, noon, afternoon, and evening periods. Analyses included descriptive statistics (aim 1) and multilevel mixed-effects models stratified by urban and peri-urban location (aim 2).

Results: Users were predominantly male and adults, and sedentary behavior was the most common activity. In urban parks, visitor numbers and sedentary users were higher on weekend days than on weekdays, and reached their highest levels in the evening (total: $\beta = 4.256$, $p < 0.001$; sedentary: $\beta = 3.015$, $p < 0.001$), followed by the afternoon (total: $\beta = 3.882$, $p < 0.001$; sedentary: $\beta = 2.921$, $p < 0.001$) and midday (total: $\beta = 1.204$, $p < 0.05$; sedentary: $\beta = 1.272$, $p < 0.001$). In peri-urban parks, visitor numbers and sedentary users were higher on weekends, and a significant increase in overall visitors was observed only in the evening ($\beta = 1.063$, $p < 0.05$).

Conclusion: Findings reveal context-specific patterns in park use and sedentary behavior, highlighting the need to

SYMPOSIUM

promote more active engagement in these settings. These insights can inform future interventions and policies aimed at creating public park environments that better support active behaviors.

S.3.46-2

Designing Urban Green Spaces for Active Ageing: Perspectives from Older Adults in Indian Megacities

D. Adlakha¹, M. Krishna²

¹TU Delft, Delft, Netherlands, ²Foundation for Research and Advocacy in Mental Health, Mysore, India

S.3.46 Policies and environments: Public green spaces as health-promoting environments across continents: integrating observational evidence, lived experiences and methodological innovation

Room 1, May 30, 2026, 8:00 AM - 9:00 AM

Purpose: Urban green spaces (UGS) are increasingly recognised as vital for promoting physical activity, social engagement, and mental well-being among older adults. In rapidly urbanizing countries like India, where the ageing population is growing, understanding how UGS influences the health of older adults is crucial. This study explores the perceptions and experiences of older adults regarding UGS in two Indian megacities.

Methods: A qualitative study was conducted in Mumbai and Bengaluru to capture in-depth insights from older adults. Semi-structured interviews (n=60) were conducted with participants aged 60 and above from diverse socio-economic neighborhoods. Thematic analysis was used to identify key patterns and themes related to accessibility, usability, safety, and the contribution of UGS to physical and social well-being.

Results: Older adults valued well-maintained UGS featuring shaded walking paths, seating, and open areas for exercise and social interaction. Such spaces facilitated regular physical activity, reduced social isolation, and fostered community engagement. Conversely, poor pedestrian infrastructure, safety concerns, and limited amenities in low-income neighborhoods restricted UGS use. Participants highlighted the need for inclusive design, culturally appropriate programming, and active community involvement in planning and maintaining UGS to ensure they meet the needs of older adults.

Conclusion: UGS are vital infrastructure for supporting active ageing in Indian megacities. Urban planning and policy should prioritize the development of accessible, safe, and inclusive green spaces tailored to older adults' needs. Equitable resource allocation and community participation are critical to maximizing the health and social benefits of UGS, ensuring all older adults—regardless of socio-economic status—can access spaces that support physical activity, social connection, and overall well-being.

S.3.46-3

A Virtual Walk in the Park: Opportunities and Challenges of Virtual Reality in Public Health Research with Older Adults

A. Van Puyvelde¹, N. Jacobs², J. Van Cauwenberg³, D. Van Dyck¹, B. Deforche^{2,4}

¹Ghent University, Department of Movement and Sports Sciences, Ghent, Belgium, ²Ghent University, Department of Public Health and Primary Care, Ghent, Belgium, ³Université Libre de Bruxelles, School of Public Health, Brussels, Belgium, ⁴Vrije Universiteit Brussel, Department of Movement and Sport Sciences, Brussel, Belgium

S.3.46 Policies and environments: Public green spaces as health-promoting environments across continents: integrating observational evidence, lived experiences and methodological innovation

Room 1, May 30, 2026, 8:00 AM - 9:00 AM

Purpose: Parks are vital for promoting healthy ageing, yet their renewal involves significant time, cost, and irreversible changes. Virtual reality (VR) offers a promising tool to evaluate design options prior to the implementation of environmental changes. This study examined the feasibility and engagement of VR as a participatory method to use with older adults from low-income neighbourhoods.

Methods: A qualitative study was conducted with 16 older adults from low-income neighbourhoods in Ghent, Belgium. Participants walked through two virtual designs of an urban park using an omnidirectional VR treadmill. The "Think Aloud" method was used to capture participants' real-time reflections during the VR walk. Additionally,

paper-based questionnaires on demographics, VR sickness, and VR presence were administered and subsequently orally discussed in more detail with each participant. Descriptive statistics were analysed in IBM SPSS, and qualitative data were transcribed verbatim and analysed using inductive qualitative content analysis in MAXQDA.

Results: Participants had a mean age of 72 years (SD=5.91); most were female, had low educational attainment, and reported (very) good perceived physical, mental, and social health. On average, participants spent 22 minutes and 33 seconds (SD=11.70 minutes; min=5.08 minutes; max=45.45 minutes) walking in the VR environments. However, 50% of the participants experienced moderate to severe motion sickness. Walking on the omnidirectional treadmill was perceived as unnatural and tiring by participants. However, participants also indicated that the VR images were realistic and immersive, that they enjoyed the experiment and that they considered VR a more effective tool for visualising environmental changes compared to traditional formats such as floor plans, 2D images, or 3D maquettes.

Conclusion: Although VR is promising as a pre-implementation evaluation method for urban design in public health research, future studies should consider alternative VR setups to enhance comfort and accessibility for older adults, and to prevent motion sickness and physical strain.

S.3.47-1

Why Do We Sit so Much? A Sensor-triggered Event-based Ecological Momentary Assessment Study of Habit and Reward during Prolonged Sedentary Behavior in Older Adults

S. Compernelle^{1,2}, L. Van de Velde¹, B. Gardner³, G. Cardon¹

¹Ghent University, Ghent, Belgium, ²Research Foundation Flanders (FWO), Brussels, Belgium, ³University of Surrey, Guildford, United Kingdom

S.3.47 Cancer prevention and management: Beyond intention: capturing automatic processes in physical activity and sedentary behavior through innovative methods

Room 2, May 30, 2026, 8:00 AM - 9:00 AM

Purpose: Sedentary behavior (SB) poses significant physical and mental health risks, particularly for older adults who spend much of their day sitting. Despite awareness of these risks, SB remains high, suggesting that automatic rather than reflective processes drive this behavior. While reflective processes have been widely studied, automatic processes—including habits and reward-driven behavior—are rarely examined. This study aimed to examine how habit strength and reward value contribute to SB in daily life, and assessed automatic and reflective motivation of prolonged SB.

Methods: We conducted a 14-day intensive longitudinal study with 105 older adults. Participants wore a Fitbit, an ActivPAL, and used a smartphone ecological momentary assessment (EMA) app. Event-based EMA questionnaires were triggered after 30 consecutive minutes of SB, up to six times per day, assessing activity type, perceived reward, and habit strength. At the end of the study, participants self-reported automatic and reflective motivation toward prolonged SB. Descriptive statistics characterized prolonged bouts, linear mixed models tested reward-habit associations, and structural equation modeling identified key determinants.

Results: Prolonged sedentary activities were generally perceived as rewarding ($M = 9.55$, $SD = 1.6$; scale 0–18), with social interactions ($M = 10.8$, $SD = 1.1$) and job-related tasks ($M = 10.3$, $SD = 1.9$) rated as most rewarding. Habit strength for sedentary behavior was relatively high ($M = 5.6$, $SD = 0.7$; scale 1–7). Higher perceived reward was associated with stronger habits ($B = 0.01$, $p = 0.01$). Structural equation modeling further showed that automatic motivation was positively related to prolonged sedentary behavior ($B = 0.30$, $p < 0.01$), whereas reflective motivation was not ($B = 0.13$, $p = 0.23$).

Conclusion: Combining innovative sensor-triggered EMA with self-reported measures of automatic motivation enabled the capture of real-world processes underlying sedentary behavior. Among older adults, prolonged SB appears primarily driven by automatic, reward-based processes, resulting in strong and resistant habits. Interventions should therefore focus on disrupting automatic cues and promoting value-based alternatives that retain the rewarding aspects of sedentary activities while encouraging regular interruptions.

SYMPOSIUM

S.3.47-2

Feeling Movement Differently? A Multimodal Exploration of Affective Responses during Physical Activity in Young Adults with and without Intellectual Disabilities

L. Maenhout^{1,2}, M. Bigliassi³, B. Cheval⁴, G. Pourtois⁵, D. Van Dyck¹

¹Ghent University, Department of Movement and Sports Sciences, Ghent, Belgium, ²Research Foundation Flanders (FWO), Brussels, Belgium, ³Florida International University, Department of Teaching and Learning, Miami, United States, ⁴Ecole Normale Supérieure Rennes, Department of Sport Sciences and Physical Education, Bruz, France, ⁵Ghent University, Department of Experimental Clinical and Health Psychology, Ghent, Belgium

S.3.47 Cancer prevention and management: Beyond intention: capturing automatic processes in physical activity and sedentary behavior through innovative methods

Room 2, May 30, 2026, 8:00 AM - 9:00 AM

Purpose: Dual-process theories propose that behavior stems from the interplay of two systems: a fast, automatic, emotion-based (affective) system and a slower, deliberate, reasoning-based (cognitive) system. While affective experiences during physical activity (PA) are increasingly recognized as key drivers of PA behavior in the general population, this aspect has received little attention among individuals with intellectual disabilities (ID). The limited evidence shows mixed findings, with some studies suggesting reduced pleasure, underscoring the need to better understand how individuals with ID experience PA. Because affect is an abstract and often difficult-to-express construct—particularly for those with communication challenges—novel methods are needed to capture affective responses more accurately. This study investigates automatic affective responses to PA in young adults with and without ID using a multimodal approach and explores how these responses differ across activity intensities.

Methods: Participants aged 18–30 years—half with ID and half without—will complete a 15-minute cycling protocol on a cycle ergometer in a controlled laboratory setting, consisting of three 5-minute phases (light, moderate, and high intensity). Intensity will be individually calibrated using the heart rate reserve method to ensure comparable physiological load. Affective responses will be assessed through a multimodal approach combining:

- (1) electroencephalography (EEG) to measure neural correlates of affect;
- (2) AI-based facial expression analysis to detect real-time affective cues via a smartphone camera; and
- (3) self-reported affect using the Feeling Scale.

A semi-structured interview will follow to contextualize and enrich participants' experiences.

Results: This exploratory study will provide insights into how individuals with ID experience PA at different intensities and whether these affective patterns diverge from those of peers without ID. We hypothesize that affective responses will be comparable at low intensity but increasingly distinct at higher intensities, where greater demands on emotion regulation and attentional control may challenge individuals with ID. Data collection will commence in December 2025, with preliminary results showcased during the symposium. Results from the ongoing facial expression validation at FIU will also be presented.

Conclusion: The focus will be on how automatic affective responses are captured using a multimodal, minimally intrusive approach, advancing inclusive methods for understanding affective responses during PA.

S.3.48-1

Improve Equity: Using Participatory Methods to Cocreate Policy Solutions that Reduce Obesity-related Health Inequity in Vulnerable Neighborhoods

J. Pronk¹, M. García Sierra², A. Kis³, A. Luszczynska⁴, S. Sakarya⁵, P. van Empelen^{1,6}, The Improve Equity Team

¹The Netherlands Organization of Applied Scientific Research (TNO), Health & Work, Leiden, Netherlands, ²Foundation for the Promotion of Health and Biomedical Research of the Valencian Community (Fisabio), Valencia, Spain, ³HafenCity University Hamburg, Hamburg, Germany, ⁴SWPS University, Wrocław, Poland, ⁵Koç University Istanbul, Istanbul, Turkey, ⁶Leiden University, Leiden, Netherlands

S.3.48 Participatory Research in Health Promotion: Participatory approaches in health equity: insights from three European projects under the scope of ERA4Health partnership-Health Equity

Room 3, May 30, 2026, 8:00 AM - 9:00 AM

Purpose: This study examined how citizens from vulnerable (low-socioeconomic) neighborhoods can be directly involved in local policy planning to reduce obesity-related health inequities. The main research question is: Can participatory cocreation strategies effectively inform systemic policy interventions across diverse European contexts? The innovative aspect of this study is the integration of citizen-driven cocreation with advanced participatory modeling methods to design, prioritize, and tailor multilevel policy interventions to the local context.

Methods: Vulnerable neighborhoods were selected as living labs in five European countries (Netherlands, Germany, Poland, Spain, Turkey). To facilitate active citizen involvement, we established stakeholder communities (50% citizens, 25% local professionals, and 25% policymakers) and developed a three-phase cocreation workshop approach with participatory methods (i.e., the Improve Equity Approach). First, we used asset mapping to identify community strengths (e.g., people, services, physical places) and create visual maps of local assets and gaps. Second, we used system modeling to develop a model of multilevel factors contributing to obesity and integrated the local input (phase 1) to enable the generation of tailored interventions. Finally, we used digital (twin) simulation modeling to prioritize interventions (phase 2) through visualizations and simulations of their potential impact. The participation process in all workshops was evaluated (i.e., process evaluation).

Results: Communities were established in all countries and are in different stages of implementation. Some living labs had initial difficulties with recruiting citizens. Intermediate reports across living labs indicate high citizen engagement and a positive, productive atmosphere. Participants felt respected and motivated. Workshop goals were rated as very clear and methods used were positively evaluated. Overall, participants—specifically citizens and professionals—valued being included in policy intervention development through small-group discussions. However, perceived potential impact on neighborhood improvement was mixed (range: neutral to strongly agree). Full results, including cross-country differences, are presented at the symposium.

Conclusion: The Improve Equity Approach demonstrated feasibility and acceptability of participatory, systemic policy intervention cocreation in vulnerable neighborhoods. It combines citizen input with advanced modeling tools to offer an innovative framework for addressing obesity-related health inequities. Intermediate reports suggest the approach can support obesity-related equity improvement in vulnerable neighborhood through cocreation, although sustaining citizen engagement remains challenging.

S.3.48-2

Insights in Mechanisms Driving Outdoor in Children: A Multi-country Perspective

R. Wink^{1,2}, L. Klaufus^{1,2}, M. Chin A Paw^{1,2}, T. Altenburg^{1,2}

¹Amsterdam University Medical Centers, Public and Occupational Health, Amsterdam, Netherlands, ²Amsterdam Public Health Research Institute, Health Behaviors and Chronic Diseases, Amsterdam, Netherlands

S.3.48 Participatory Research in Health Promotion: Participatory approaches in health equity: insights from three European projects under the scope of ERA4Health partnership-Health Equity

Room 3, May 30, 2026, 8:00 AM - 9:00 AM

Purpose: Globally, an increasing number of children does not meet current guidelines for physical activity. In the B-Challenged project, actions are co-created together with children themselves and a network of adult actors to improve outdoor play. In this presentation, a comparison of mechanisms driving outdoor play and co-created action ideas amongst the participating countries in the project will be discussed.

Methods: In five European countries (Denmark, Germany, Poland, The Netherlands, and Spain), facilitators organized participatory sessions with action teams of children aged 9-12 years and adult actors. The number of participants ranges from 21 children in Germany to 54 children and 15 adults in Denmark. In several countries, the recruitment of adult actors is still ongoing. In the first phase, action teams and adult actors engaged in storytelling activities identifying what outdoor play activities children engage in and why, and what potential barriers to outdoor play are. Based on this, researchers identified mechanisms driving outdoor play, visualised in Causal Loop Diagrams (CLDs). In the next phase, action teams selected points for change (i.e., leverage points) and brainstormed actions that could make a big difference to a lot of children. To maximize impact, facilitators prompted the action teams to think about actions at different system levels, based on the Action Scales Model.

Results: The CLDs showing mechanisms driving outdoor play are compared, showing the overlap and differences in the mechanisms driving these behaviours in various European contexts. Preliminary results from the Danish and Dutch context show that social connectedness (i.e., having friends to play with) is an important driver for outdoor play in both The Netherlands and Denmark, whereas homework was only mentioned as a barrier to outdoor play in the

SYMPOSIUM

Dutch context. Similarly, action ideas are compared amongst each other.

Conclusion: This presentation discusses the mechanisms driving outdoor play from a multi-country perspective. Comparing the CLDs from each local context and the subsequently developed action ideas will show which mechanisms and action ideas are relevant in a larger European context, and which mechanisms and actions apply to the specific local contexts.

S.3.48-3

Challenges in Applying Participatory Action Research with Adolescents in Schools – The Connection Project

B. Teixeira^{1,2,3}, C. Carvalho^{1,3}, M.P. Santos^{4,5,6}, E. Ramos^{1,6,7}, C. Lopes^{7,1,3}

¹EPIUnit ITR, Institute of Public Health, University of Porto, Porto, Portugal, ²Faculty of Nutrition and Food Sciences, University of Porto, Porto, Portugal, ³ITR- Laboratory for Integrative and Translational Research in Population Health, Porto, Portugal, ⁴Faculty of Sport, University of Porto, Porto, Portugal, ⁵Research Centre in Physical Activity, Health and Leisure (CIAFEL), Porto, Portugal, ⁶ITR- Laboratory for Integrative and Translational Research in Population Health, PortoPOR, Portugal, ⁷Faculty of Medicine of the University of Porto, Department of Public Health and Forensic Sciences and Medical Education, Porto, Portugal

S.3.48 Participatory Research in Health Promotion: Participatory approaches in health equity: insights from three European projects under the scope of ERA4Health partnership-Health Equity

Room 3, May 30, 2026, 8:00 AM - 9:00 AM

Purpose: The CONNECTION project aims to promote health equity by improving dietary habits and physical activity (PA) among adolescents living in socioeconomically disadvantaged contexts through co-created interventions. This study focuses on the Portuguese experience, examining methodological challenges and opportunities in applying Participatory Action Research (PAR) with adolescents in the school context. The innovative aspect lies in adapting PAR principles to engage young people as co-researchers and co-designers of health-promoting interventions, while addressing ethical, practical, and contextual constraints inherent to these environments.

Methods: In the Porto metropolitan area, a Participatory Action Research (PAR) approach was implemented with three Action Teams across two public schools from disadvantage areas (addressing diet and PA), among adolescents aged 12–17 years old (n ≈ 60). Across seven participatory sessions, data were generated by youth through *mapping*, *photovoice*, and *storyboard* activities, complemented by 25 interviews and one focus group with teachers, school staff, caregivers, and municipal representatives. The process emphasized co-creation, reflection, and joint decision-making. A grounded theory-informed thematic analysis identified methodological and relational challenges during implementation.

Results: Key challenges included managing time within sessions, sustaining adolescents' motivation, and balancing autonomy with structure. Institutional barriers, such as limited time, staff availability, and turnover also hindered continuity. Differences between the two schools reflected variations in stakeholder engagement, as higher involvement facilitated collaborative discussion and refinement of strategies, while lower engagement constrained co-creation and feasibility. Stakeholders' motivation, availability, and capacity influence which actions can be realistically implemented. Ensuring that results led to concrete changes and keeping adolescents engaged across sessions were additional barriers. Despite these difficulties, the process strengthened trust, dialogue, and ownership among adolescents and adult stakeholders.

Conclusion: Applying PAR in schools proved demanding yet transformative. Success required strong institutional commitment, flexible facilitation, and adequate time for real impact. While engagement and sustainability remain challenging, findings show that adolescents can meaningfully shape health-promoting interventions. Lessons learned advance participatory approaches in behavioral diet and physical activity research, underscoring both the value and complexity of empowering youth in vulnerable conditions as active change agents.

S.3.49-1**Maintaining Early Childhood Education Settings as Screen-free Zones: Exploring the Impact of Screen Use on Early Childhood Mental Health****S. Phillips¹**¹*Western University, London, Ontario, Canada***S.3.49 Implementation and scalability: Are Screens Enhancing or Hindering Positive Movement and Nutrition Behaviours in Early Childcare Environments?****Room 4, May 30, 2026, 8:00 AM - 9:00 AM**

Purpose: Early childhood is a formative period of development where key health behaviours and habits are established. Increasing evidence links screen use to mental health indicators throughout childhood, which has garnered increasing attention from researchers, educators, parents, and healthcare professionals. This presentation will explore screen use and other sedentary behaviours on a range of early life mental health indicators.

Methods: A systematic review was conducted to examine associations between screen use and other sedentary behaviours on a range of early life mental health indicators. This review distinguished between screen use/engagement and other sedentary behaviour to explore their distinct effects on mental health indicators of young children.

Results: Findings indicate that the use of screens during early childhood is associated with poorer mental health indicators. While some contexts or reasons for screen use may be less harmful, this research does not support screen use in early childhood education settings. This work also highlights that sedentary time and other sedentary activities may have varying associations with early childhood mental health indicators, emphasising the importance of evaluating these behaviours independently in the context of early childhood education.

Conclusion: Limiting screen use in early childhood may be an advantageous method to prevent adverse mental health outcomes. Keeping early childhood education settings as screen-free zones may help reduce the risk of harm of screen use on young children's health. These settings offer an ideal health promoting space for young children, including prioritisation of other sedentary behaviour activities associated with positive health outcomes, play, physical activity, and socialisation with peers and educators. This presentation will emphasise the importance of maintaining early childhood education environments as screen-free spaces, to support the health and wellbeing of young children from the earliest years.

S.3.49-2**Empowering Healthy Habits: In Favour of Screens to Promote Positive Movement and Nutrition Behaviours for Young Children****G. Thomas¹**¹*The University of Queensland, Health and Wellbeing Centre for Research Innovation, Brisbane, Australia***S.3.49 Implementation and scalability: Are Screens Enhancing or Hindering Positive Movement and Nutrition Behaviours in Early Childcare Environments?****Room 4, May 30, 2026, 8:00 AM - 9:00 AM**

Purpose: Screens are a prominent part of children's lives, and their role in early education is evolving. Often seen as sources of sedentary behaviour, screens can also engage young children in movement and nutrition education. Interactive apps, videos, and digital games can teach physical activity skills, promote active play, and enhance understanding of healthy eating. By using screens strategically, educators can leverage their appeal to motivate children to move more and make better food choices. This presentation will explore how screens can be integrated into early childcare settings to support positive movement behaviours and healthy eating habits.

Methods: A rapid review was conducted to examine existing research on the use of screens in early learning settings, focusing on studies that evaluated screen-based interventions aimed at promoting physical activity and healthy eating. Additionally, original data from pilot programs utilizing app-based and interactive digital content were reviewed, highlighting how screens can effectively engage children in active learning and movement-based activities.

Results: Findings suggest that screens, when used intentionally and as part of a broader curriculum, can be valuable tools for fostering engagement in physical activity and reinforcing healthy eating habits among young children. Programs incorporating movement-based games, interactive nutrition lessons, and digital storytelling have shown to encourage active play, enhance motor skills, and improve children's understanding of healthy food choices. Moreover,

SYMPOSIUM

screens can serve as educational platforms that introduce variety and novelty, making lessons on physical activity and nutrition more appealing and accessible for young learners. These positive outcomes demonstrate that, with appropriate content and screen time management, digital tools can play a supportive role in promoting healthier behaviours in early childcare settings.

Conclusion: The integration of screens into early childcare environments offers opportunities to innovate how movement and nutrition are taught to young children. By harnessing the interactive and engaging nature of digital technology, early learning programs can complement traditional physical activity and nutrition education. The findings suggest that developing guidelines on effective screen use, which balance educational content with active play, can advance practices in behavioural nutrition and physical activity within early childhood education.

S.3.51-1

Navigating from Theory to Practice: Lessons from Implementing a City Wide Systems Approach to Urban Health in Amsterdam

C. Dijkstra¹, G. Muru¹, F. van Nassau¹, N. van der Poel², C. Renders², A. Verhoeff³

¹Amsterdam UMC, Public and Occupational Health, Amsterdam, Netherlands, ²Vrije Universiteit Amsterdam, Health Sciences, Amsterdam, Netherlands, ³GGD Amsterdam, Healthy Living, Amsterdam, Netherlands

S.3.51 Systems Science: From theory to practice: implementing systems approaches to complex health challenges
Room 6, May 30, 2026, 8:00 AM - 9:00 AM

Purpose: Implementing systems approaches in public health practice is widely advocated but remains challenging. In Amsterdam, the Netherlands, an city wide systems approach was developed to address complex health challenges, such as obesity, mental health, and substance use, through area-based collaboration. This study explores how the approach was implemented, how professionals experienced the process, and what mechanisms created tensions between the system's ambitions and the realities of practice. The study contributes to understanding why implementing systems approaches is difficult and how system-level change unfolds in institutional contexts not yet designed for it.

Methods: A qualitative process evaluation was conducted using document analysis, semi-structured interviews, participant observation, and Ripple Effect Mapping workshops. An interpretive, iterative thematic analysis identified patterns in how professionals navigated tensions between the theoretical principles of systems thinking and the operational logics of public health organizations.

Results: The systems approach strengthened collaboration between the public health department ("Healthy Living") and district administrations, building new interprofessional connections, shared understanding, and early integrative actions. Yet progress was non-linear and shaped by underlying mechanisms across five domains. Adaptive governance revealed constant negotiation between structure and flexibility, as evolving contexts demanded ongoing role alignment. Institutional silos limited cross-domain collaboration, with thematic programs and fragmented mandates clashing with integrative ambitions. Language and meaning emerged as barriers, the term "systems approach" was perceived as abstract, requiring continuous translation into shared, practical language. The theory-practice gap became visible when conceptual tools (e.g., iceberg model, system maps) inspired insight but proved difficult to operationalize for practitioners seeking concrete action. Finally, temporal tensions reflected the slow pace of systemic change, where relational outcomes, trust, learning, and shared understanding, were vital yet often undervalued.

Conclusion: Implementing a systems approach exposed productive tensions between institutional order and emergent collaboration. These tensions are not failures but essential drivers of change. They prompt reflection, challenge routines, and foster collective learning. Recognizing and working with these tensions, rather than against it, is key to embedding systems thinking in public health and enabling structural, equitable responses to complex urban health challenges.

S.3.51-2

Building, Refining and Applying a Dynamic Theory of Change to Support a Systems-based Evaluation of a Stakeholder-led Intervention in Birmingham, UK

A. Sawyer¹, K.P. Adeosun², R. Loopstra², M. White¹

¹University of Cambridge, IMS Epidemiology Unit, Cambridge, United Kingdom, ²University of Liverpool, Department of Public Health, Policy and Systems, Liverpool, United Kingdom

S.3.51 Systems Science: From theory to practice: implementing systems approaches to complex health challenges
Room 6, May 30, 2026, 8:00 AM - 9:00 AM

Purpose: Systems thinking conceptualises interventions as events in complex adaptive systems. Consequently, interventions can be theorised as interacting with adaptive causal mechanisms generating outcomes. This paper reports the development and application of a 'dynamic' theory of change (ToC) to underpin a realist-informed, systems-based evaluation of the health and environmental impacts of a surplus food redistribution hub serving the community food sector.

Methods: The study is part of the Mandala Consortium: a 5-year project exploring the urban food system in Birmingham, UK. Group Model Building techniques were used with 16 stakeholders to develop a causal loop diagram (CLD) visualising the mechanisms sustaining low provision of healthy, fresh food in the community food sector (e.g. food aid). Leverage point identification, action ideation and prioritisation activities informed workshops with stakeholders to co-develop a surplus food redistribution hub located in the city's wholesale market. Using documentation and workshop notes, the sector-wide CLD was systematically converted into a 'dynamic' ToC incorporating feedback loops to theorise: (1) variations in intervention design to permit planned adaptations over time and (2) supporting and limiting influences of the wider system.

The ToC was refined through analysis of realist-informed interviews with stakeholders during intervention implementation. Hypotheses derived from the ToC using context-mechanism-outcome configurations will be tested using qualitative and quantitative data on the recovery of food waste, market traders' attitudes and practices around food redistribution and uptake of redistributed food in the community food sector.

Results: The dynamic ToC included: 22 nodes representing intervention inputs (5), activities (5), outputs (1), short-term (5) and long-term (3) outcomes and moderating influences (3); and 47 directed connections. From these, we identified >20 distinct reinforcing and balancing feedback loops which could support or suppress intervention effectiveness over time.

Challenges in refining and applying the dynamic ToC to inform evaluation included: working with real-world actors reliant on short-term funding to capture intervention adaptations; prioritising hypotheses for evaluation; identifying longitudinal data sources; integrating uncertainty in evaluation planning.

Conclusion: Detailing the steps taken to build, refine and apply a dynamic ToC supports methodological development for systems-based evaluation. Reported challenges illustrate the complexities of evaluating action in complex adaptive systems.

S.3.51-3

The Delivery of a Participatory System Dynamics Approach in Local Obesity Prevention in Amsterdam, the Netherlands: Walking the Broader Path

J. O'Mara¹, W. Waterlander¹, K. Stronks¹

¹AmsterdamUMC, Public and Occupational Health, Amsterdam, Netherlands

S.3.51 Systems Science: From theory to practice: implementing systems approaches to complex health challenges
Room 6, May 30, 2026, 8:00 AM - 9:00 AM

Purpose: Increasingly, programs are applying methods rooted in (participatory) system dynamics (SD) to understand and address the root causes of complex public health problems, such as childhood obesity. However, the novelty and intricacy of implementing such approaches has left researchers and professionals 'muddling through' often resulting in a narrow conceptualization and implementation, which is fundamentally at odds with the call for a broader path that truly embraces complexity. This study aimed to reflect and provide further guidance on the process of delivering

SYMPOSIUM

a participatory SD approach by identifying ‘points of friction’ that emerged while trying to ‘walk the broad path’.

Methods: We conducted a qualitative process evaluation of the LIKE project – a participatory SD project for obesity prevention among youth in Amsterdam, the Netherlands. Data was collected from three sources: (1) Ripple Effects Mapping (REM) a qualitative participatory method aimed at identifying intended and unintended consequences of actions, (2) interviews with stakeholders and (3) an impact consensus process. We used inductive and deductive thematic analysis, supplemented with insights from two central LIKE consortium members, to identify recurring themes and categorize them into points of friction.

Results: We identified four central ‘points of friction’: (1) embracing vs. reducing complexity, (2) collaborative and cross-sectoral working vs. working in expertise silos, (3) working adaptively vs. project-based work, and (4) broad and adaptive skillset vs. topical expertise. For each friction we explain what we did, what went well, what did not go well and the resulting friction. For example, despite efforts to work adaptively through flexible budgets and engaging the funders in learning spaces, friction arose from a mismatch between this flexibility and the more static goals of delivering a project within a timeline of 5-years.

Conclusion: Participatory SD approaches are aimed at addressing complex problems. However, friction arises when these approaches run into existing paradigms, structures and ways of working. We provide reflections from real-world experience in trying to ‘walk the broad path’ and weave these into existing theory to propose a practical framework for delivering a participatory SD approach.

S.3.52-1

Improving Food Is Medicine Access and Impacts: Screening and Enrollment Insights from Multiple Research Studies

E. Calloway¹, C. Long¹, B. Houghtaling¹, E. Short¹, V. Zigmont¹, E. Duffy¹, D. Brucker², H.J. Kim², A. Floyd Clark¹, C. Milburn Atkinson¹, E. Mitchell¹, S. Palmer¹, G. Talavera¹, G. Stott¹, L. Flournoy¹, M. Isack¹, A.L. Yaroch¹

¹Center for Nutrition and Health Impact, Omaha, United States, ²University of New Hampshire, Institute on Disability, College of Health and Human Services, Durham, United States

S.3.52 Motivation and behavior change: Fitting Food is Medicine to Context: Implementation Lessons from Programs in the U.S. and Israel

Room 7, May 30, 2026, 8:00 AM - 9:00 AM

Purpose: Food is Medicine (FiM) programs use a “screen-and-refer” approach within healthcare-community partnerships to address food insecurity (FI), nutrition insecurity (NI), and diet-related disease. Despite global FiM advancements, limited implementation research has examined screening and enrollment. The purpose of this presentation is to describe findings across multiple studies assessing FiM screening and enrollment processes to inform best practices.

Methods: Study 1 is a mixed-methods study including participant interviews (n=35) and surveys (n=1,490) from a national FiM initiative, which included assessment of participant screening experiences and examination of enrollment characteristics. Study 2 is a qualitative investigation of patients’ (n=10) experiences with FI/NI screening items. Study 3 is a qualitative examination of the FI experience of people with intellectual and developmental disabilities (IDD) (n=22) to inform screener development. Study 4 is a qualitative study of FiM implementer interviews (n=15) from another national initiative, which included questions about enrollment and screening. All studies took place in the USA.

Results: In studies 1 & 2, FiM participant interviewees emphasized the need for comfort and trusting relationships with staff conducting the screening. Additionally, Study 2 showed that participants interpreted screening questions about FI (“access to enough food”) differently than NI (“access to healthy food”). Study 3 found that groups experienced FI differently. Participants with IDD described unique aspects of their FI experience, such as sensory/texture needs and cooking struggles, not captured by existing screeners. In Study 4, FiM implementers emphasized careful consideration of enrollment criteria to ensure participants fit well and were motivated to engage. Study 1 also showed that participants in FiM programs with stricter enrollment criteria (diet-related condition + FI) compared to looser criteria (only FI) showed increases in fruit/vegetable intake and decreases in ER visits, hospitalizations, and forgoing medication (all ≥14% improvement, p<0.05).

Conclusion: Findings from these studies augment our understanding of how to screen and enroll participations to maximize FiM access and impacts. Facilitating participant trust and comfort are key overall. Screening questions chosen and tailoring to sub-populations can affect who gets enrolled. Enrollment criteria decisions can also impact participants’ engagement and outcomes.

S.3.52-2

Potential Unintended Consequences of a Fresh-only Produce Prescription Program Policy in the United States

B. Houghtaling¹, N. Zhang^{2,3}, A. Yaroch¹, C. Milburn Atkinson¹, **C. Byker Shanks¹**

¹Center for Nutrition & Health Impact, Omaha, United States, ²Cincinnati Children's Hospital Medical Center, Division of Biostatistics & Epidemiology, Cincinnati, United States, ³University of Cincinnati College of Medicine, Department of Pediatrics, Cincinnati, United States

S.3.52 Motivation and behavior change: Fitting Food is Medicine to Context: Implementation Lessons from Programs in the U.S. and Israel

Room 7, May 30, 2026, 8:00 AM - 9:00 AM

Purpose: Policy is a key contextual factor that influences program design and implementation. In the United States (USA), produce prescription programs (PPRs), a type of Food is Medicine (FiM) intervention, engage the healthcare sector to screen eligible patients (low income, diet-related chronic disease risk) and prescribe free/reduced cost fruits and vegetables (FVs). A key federal policy for PPR restricts eligible FVs to fresh. This presentation will describe potential unintended consequences of a fresh-only policy for PPRs.

Methods: The USA 2018 Farm Bill established PPRs under the Gus Schumacher Nutrition Incentive Program (GusNIP) and designated a fresh-only policy. GusNIP also established the Nutrition Incentive Program Training, Technical Assistance, Evaluation, and Information Center (NTAE) for technical assistance and evaluation support. First, key literature on fresh FV accessibility in the USA was reviewed. Second, examples on limitations of a fresh-only policy were sourced from NTAE administrative data. Third, a nationally representative secondary data analysis of the most recent National Household Food Acquisition and Purchase Survey (FoodAPS) was carried out using regression modeling ($\alpha=0.05$) to explore the relationship between PPR eligibility and FV purchasing (fresh, frozen, canned, and dried FVs), including how multi-level factors shape the relationship.

Results: Key literature in the USA shows FV accessibility is influenced by several multi-level factors that limit fresh FV accessibility and utilization among populations with low income. NTAE administrative data found that while GusNIP grantees implementing PPRs can petition for exemptions to the federal fresh-only policy, this process can be burdensome and intimidating. Last, results of the secondary data analysis that classified FoodAPS households as eligible ($n=2,079$) or ineligible ($n=2,288$) for PPR found that while household eligibility for PPR was not related to the amount or variety of FVs purchased, various multi-level factors moderated the relationship. For example, racial/ethnic identity, farmers market access, and geographic location differentially impacted fresh, frozen, and canned FV purchases among PPR eligible households ($p<0.05$).

Conclusion: PPR policies restricting eligible FVs to only fresh may not fit local population needs. Allowing other forms of FVs could better support PPR goals to improve FV purchasing and intake. The US-centric approach could guide PPR decisions in international contexts.

S.3.52 Motivation and behavior change: Fitting Food is Medicine to Context: Implementation Lessons from Programs in the U.S. and Israel

Room 7, May 30, 2026, 8:00 AM - 9:00 AM

SYMPOSIUM

Purpose: Produce Prescription (PPR) programs have become increasingly common in the USA, yet persistent challenges remain before they can become mainstream —how to define eligible patients, finance interventions sustainably, and integrate agriculture–health systems? This Israeli–USA collaboration, aims to address these questions in Israel’s first randomized PPR effectiveness trial. The purpose is twofold:

- (1) test feasibility and effectiveness of PPR in a managed care system with universal health coverage, and
- (2) generate comparative evidence to identify which elements of PPR are universal versus context-specific—to inform optimization of studies everywhere for medical, social, and economic impact.

Methods: The trial will be implemented in Meuhedet HMO diabetes clinics in collaboration with Sheba Medical Center, the Hebrew University of Jerusalem, the Israel Ministry of Health, Leket Israel (national food-rescue organization), and Eshel Chabad, which administers the national food-assistance program. Adults with type 2 diabetes and nutrition insecurity will be randomized to receive a weekly PPR paired with nutrition education or standard care. Outcomes include:

- (1) clinical efficacy
- (2) economic impact; and
- (3) feasibility and implementation.

The design aligns with GusNIP standards in the USA to enable binational comparison, while adapting to the unique Israeli context of universal healthcare, integrated EMR systems, absence of SNAP/WIC, reliance on non-profits for food provision, and diverse dietary and cultural norms.

Results: Complex design considerations will be discussed along with the local Israeli context, highlighting how universal PPR challenges and past USA experience have informed local design to enable international comparison and generalizability. Design components include screening of patients for food insecurity, patient dignity, delivery of produce in the clinical setting, personalizing prescription, patient adherence, integrating governmental, health, welfare and agricultural actors.

Conclusion: This international, multi-stakeholder trial will contribute more than efficacy data; it offers a model for context-sensitive design for PPR implementation—identifying universal principles of “food is medicine” and how they might be adapted to specific health system financing, food supply structure, and cultural eating patterns. This study intends to advance global learning on how PPR can be tailored and scaled to maximize metabolic, social, and economic value.

Unhealthy Food Outlets Density around Schools in Ten Cities across Europe: An OBCT Study

L. Carmona Rosado¹, J. Díez¹, M. Raju², R. Valiente¹, N. Patel², M. Franco^{3,4}, J. Lakerveld²

¹Universidad de Alcalá, Public Health and Epidemiology Research Group, School of Medicine and Health Sciences, Alcalá de Henares, Spain, ²Amsterdam Public Health Research Institute, Amsterdam UMC, Vrije Universiteit Amsterdam, Department of Epidemiology and Data Science, Amsterdam, Netherlands, ³Adaptation Lab, BC3 Basque Centre for Climate Change, Leioa, Spain, ⁴Ikerbasque, Bilbaospas, Spain

S.3.53 Policies and environments: From Schools to Early Care: Comparative Approaches to Building Healthier Food Environments for Children

Room 8, May 30, 2026, 8:00 AM - 9:00 AM

Purpose: Obesogenic food environments around schools promote unhealthy eating behaviors and contribute to childhood obesity. This study aimed to describe the spatial distribution and density of unhealthy food outlets surrounding primary and secondary schools in ten European cities.

Methods: We conducted a descriptive ecological study in Amsterdam, Madrid, Berlin, Budapest, Helsinki, Lisbon, London, Oslo, Vienna, and Warsaw. We used Geographic Information Systems to geolocate all schools (N = 7,338) and unhealthy food outlets (N= 21,640), defined as those selling any unhealthy foods or non-alcoholic drinks for consumption on-site or elsewhere. We obtained data on schools from local administrative datasets, and on unhealthy food outlets from Google Maps, for June 2025. We counted the number of unhealthy food outlets within 5-minute walking distance from schools, representing approximately 400 m street network buffers. We used QGIS and Python for geospatial analyses and RStudio for statistical analyses. We report descriptive results, median and interquartile range (IQR), globally and by city. In addition, we show these results by primary and secondary schools.

Results: Overall, schools in European cities had a median of 4 [IQR = 10] unhealthy food outlets within a 5-minute walking distance from schools. Among the cities, Vienna had the highest density of unhealthy food outlets (median

=11, IQR = 20), followed by Warsaw (median= 10, IQR = 15) and Madrid (median = 9, IQR = 16). In contrast, cities with the least unhealthy school food environments were Helsinki (median = 1, IQR = 3), and Oslo (median= 1, IQR =5). We also observed higher median values for secondary schools, except for London and Lisbon.

Conclusion: The distribution and density of unhealthy food outlets around schools varies between cities, with cities like Vienna, Warsaw and Madrid showing a worrisome high density of such outlets. These findings serve as a starting point for gaining a better understanding of school food environments and, ultimately, for future research and health policy development.

S.3.53-2

School Food Interventions and Child Nutrition in Europe: Insights from a Scoping Review

J. Diez¹, I. Vidal¹, M. Franco², P. Dominguez-Salas¹, N. Cohen³

¹Universidad de Alcalá, Alcalá de Henares, Spain, ²Basque Center for Climate Change Research, Leioa, Spain, ³City University of New York, Department of Health Policy and Management, CUNY Urban Food Policy Institute, New York City, United States

S.3.53 Policies and environments: From Schools to Early Care: Comparative Approaches to Building Healthier Food Environments for Children

Room 8, May 30, 2026, 8:00 AM - 9:00 AM

Purpose: School settings are key for promoting healthier diets among youth; however, evidence on the effectiveness of school food interventions in Europe remains fragmented. Our aim was to map and synthesize recent evidence on school food interventions and assess their effects on nutritional outcomes among European youth. In addition, we explored how these interventions addressed equity-related findings.

Methods: Following the PRISMA-ScR guidelines, we conducted a scoping review. We launched our search strategy in PubMed and Scopus and retrieved original articles published between January 2020 and February 2025. Eligible studies included children and adolescents (aged 0–19 years) attending schools in Europe, involved a school food intervention, and assessed a diet- or anthropometric-related outcome. Titles and abstracts, and then full texts, were reviewed independently by two researchers. One researcher completed data extraction of eligible studies organizing findings by intervention type, outcomes, and impact on health equity. We registered the protocol in Open Science Framework (OSF.IO/T8KXV).

Results: Our search strategy yielded 454 articles and our screening process resulted in 26 studies. Most interventions were implemented in the Netherlands (n=7), Italy (n=4), and Poland (n=4). Out of the 16 educational interventions, 12 reported positive effects on dietary behaviors and four on weight-related outcomes. Food provision interventions (n=5), like free healthy school lunches or fruit distribution schemes, also showed positive effects on fruits and vegetable intake and nutritional knowledge. Multicomponent interventions (n=5), such as whole-school approaches, also showed consistent and sustainable positive effects on dietary behaviors and reductions in body mass index. Few studies evaluated the equity-related impact of their interventions.

Conclusion: While school food interventions show consistent positive effects on dietary behaviors, their impact on weight-related outcomes remains inconsistent. We identified persistent gaps in adolescent engagement, equity assessment, and long-term sustainability. Future interventions should promote universal access to healthy, sustainable school meals, prioritize long-term program evaluation and equity monitoring. Strengthening evidence-based, context-sensitive school food interventions is critical to achieving healthier and more equitable diets for all European children.

S.3.53-3

Assessing Farm to Early Care and Education (ECE) as an Innovative Public Health Strategy: Parent Insights on ECE Nutrition and Local Food Access

M. Knapp¹, J. McNally², S. Fleurinor², E. Munoz-Miller²

¹Xavier University of Louisiana, Public Health Sciences, New Orleans, United States, ²Food Policy Council, New Orleans, United States

SYMPOSIUM

S.3.53 Policies and environments: From Schools to Early Care: Comparative Approaches to Building Healthier Food Environments for Children

Room 8, May 30, 2026, 8:00 AM - 9:00 AM

Purpose: Many U.S. children ages five and under spend a large part of their day in early care and education (ECE) settings. ECEs can be critical environments for shaping dietary behaviors and promoting health. Farm to ECE programs, which enhance the nutritional quality of meals through local food procurement, provide experiential food and garden-based education, and connect families with local farms and produce, represent an innovative approach to improving child nutrition while supporting community-based food systems. Few studies have rigorously examined parent perceptions, key determinants of program sustainability and home-based behavior change. As part of a larger evaluation, we assessed parent perspectives on Farm to ECE programming, explored potential transfer of nutrition knowledge and behaviors from the classroom to the home, and identified opportunities to enhance family engagement with local food systems.

Methods: Baseline surveys were completed by 312 parents from eight participating ECE centers. Measures included perceptions of center food offerings and nutrition programming, knowledge and use of community food access resources, and demographic characteristics. Descriptive statistics were calculated to summarize parent characteristics and perceptions.

Results: Among respondents, 95% identified as Black or African American, and the majority were single mothers; one-third experienced household food insecurity. Although less than half (47%) of participants were familiar with Farm to ECE programming, parents supported its key activities: most agreed that centers should serve fresh, local fruits and vegetables (90%) and limit prepackaged, processed foods (77%). Most parents supported nutrition education within centers (86%) and believed that exposure to healthier options at ECEs could positively influence how they feed their children at home (81%). Awareness and utilization of local food access resources were low (11%) but the desire to learn more about resources from centers was high (90%).

Conclusion: Findings demonstrate parent support for Farm to ECE programming and its potential to influence home food environments and expand knowledge and use of local food access resources. Strengthening the connections between centers, families, communities through Farm to ECE programming offers a promising approach to improve nutrition and food security among young children and their families and support local food systems.

S.3.54-1

Introducing Resistance Training Into Primary Schools: Co-designing Project SCHOOL

J. Radnor¹, J. Oliver², R. Lloyd², S. Kennedy³, M. Stemberge²

¹Cardiff Metropolitan University, Sport and Health Science, Cardiff, United Kingdom, ²Cardiff Metropolitan University, School of Sport and Health Science, Cardiff, United Kingdom, ³Western Sydney University, School of Health Sciences, Sydney, Australia

S.3.54 Participatory Research in Health Promotion: What Is Important to Co-Create an Intervention in School Contexts? Insights of Three Different Co-Creation Process in Europe

Room 9, May 30, 2026, 8:00 AM - 9:00 AM

Purpose: Physical inactivity remains a major issue among UK children, with fewer than half meeting recommended activity levels [1]. A “proficiency barrier” in motor skills may limit participation, underpinned by low muscular strength, poor movement competency, and reduced confidence [2,3]. Schools offer ideal settings to address this, yet fewer than 2% of Welsh primary schools use resistance training as a mode of physical activity [4]. This study aimed to co-design a resistance training curriculum for primary schools and assess its feasibility for school delivery.

Methods: A working group was formed including the principal investigator and four primary teachers in South Wales, UK. Key stage 2 children also contributed by sharing preferred activities. The co-design process involved: 1) an online planning meeting; 2) a teacher training and curriculum development day; 3) delivery of a preliminary session; 4) feedback from staff and pupils; and 5) reflection meeting to refine the curriculum. The pilot trial consisted of each teacher delivering the curriculum over four weeks. Feasibility was assessed using four domains (acceptability, implementation, adaptability, and practicality).

Results: Three teachers attended 100% of co-design sessions, with one withdrawing. Following stage 3, teachers suggested delivering sessions in-place of PE, shortening sessions to under 1-hour, and ensuring games were adaptable for space and equipment. Pupils mostly enjoyed the games element of the session (64% ranked as top 2 activities), while challenges were less preferred (44%). Gymnastics were polarising, with 30% rating them as favourite, but 47%

as least favourite. Pupils found movement cards and videos helpful (95% and 83%, respectively) but wanted guidance on exercise progressions. These insights formed curriculum refinements prior to the 4-week delivery.

The curriculum reached 78 pupils and was delivered with high fidelity (>75% of planned sessions delivered) and acceptability (97% reported “good” or “excellent”). Pupils reported perceived improvements in movement skills (61%) and muscular strength (55%), though fewer noted increases in confidence (18%). Teachers observed enhanced enjoyment and motivation compared to normal PE lessons.

Conclusion: Engaging teachers and pupils in curriculum co-design produced a feasible, engaging resistance training programme. A randomised controlled trial is now required to assess its preliminary effectiveness.

S.3.54-2

A Feasibility Study of a Co-creation Approach for Developing Didactic Resources to Promote Active Commuting in Children: The IDEA-Kids Study

P. Chillón¹, A. Ramírez-Osuna¹, D. Rodríguez-Sánchez¹, N. Zurita-Corvalán¹, E.G. Bengoechea², F.J. Huertas-Delgado³

¹University of Granada, Department of Physical Education and Sports, Faculty of Sport Sciences, Sport and Health University Research Institute (iMUDS), Granada, Spain, ²University of Limerick, Department of Physical Education and Sport Sciences, Physical Activity for Health Research Centre, Health Research Institute, Limerick, Ireland, ³University of Granada, “La Inmaculada” Teacher Training Centre, Granada, Spain

S.3.54 Participatory Research in Health Promotion: What Is Important to Co-Create an Intervention in School Contexts? Insights of Three Different Co-Creation Process in Europe

Room 9, May 30, 2026, 8:00 AM - 9:00 AM

Purpose: Active commuting, such as walking and cycling, improves children’s physical activity and well-being. Previous studies suggest that school-based interventions can contribute to changes in commuting behaviours, particularly when led by teachers who interact daily with students. The Spanish’s recent educational legislation supports active commuting objectives. Consequently, this study aimed to evaluate the implementation of a participatory co-creation process involving teachers and students in developing didactic resources to foster active commuting among primary school children.

Methods: At baseline, descriptive data about participants and context were collected to understand the participants and the study setting. Participants were 6 teachers (i.e., generalist, special educational needs specialist, and a School Board member) and 4 students from 5th or 6th grade, selected by convenience from one Andalusian school and ensuring gender balance. The co-creation process included five structured online and on-site workshops over four weeks, using participatory methodologies. Implementation was evaluated through several variables: attendance and engagement, fidelity of delivery, satisfaction, perceived difficulties and enablers, and teachers’ motivation and confidence to use educational materials promoting active commuting. Data were gathered through a process evaluation questionnaire, semi-structured interviews, fidelity checklists, and pre-post teacher evaluation questionnaires.

Results: Attendance and engagement were high, as most participants attended at least four of the five workshops and actively contributed to collaborative tasks. Fidelity of delivery, assessed through fidelity checklists, showed that all workshops were implemented as planned, with only minor scheduling adaptations. Satisfaction with the process was high among participants. Perceived difficulties and enablers mainly related to time management and discussion rotation as barriers, while collaborative learning and teacher-student interaction emerged as enablers. Teachers’ motivation and confidence to apply active commuting content in their teaching increased after the co-creation process. The process produced one didactic resource: the Learning Situation “¿Caminante se hace camino? ¡Únete al camino de San Miguel!”, integrating multiple curricular areas through cooperative, problem-based, and service-learning methodologies.

Conclusion: The co-creation process was feasible and well received. Despite some participant dropout, it fostered meaningful collaboration between teachers and students and demonstrated the potential of participatory approaches to promote active commuting within the school curriculum.

SYMPOSIUM

S.3.54-3

Co-creating a Digital Behavioural Intervention to Improve Youth Well-being: The YEAH! Co-creation Protocol

G. Longworth¹, S. Chastin¹

¹Glasgow Caledonian University, Glasgow, United Kingdom

S.3.54 Participatory Research in Health Promotion: What Is Important to Co-Create an Intervention in School Contexts? Insights of Three Different Co-Creation Process in Europe

Room 9, May 30, 2026, 8:00 AM - 9:00 AM

Purpose: This study presents an innovative large-scale co-creation protocol to develop a digital behavioural intervention supporting healthier lifestyles among children and adolescents. Embedded within YEAH!, a Horizon Europe project across seven countries, the protocol combines a standardised procedure, which will undergo local co-adaptation, ensuring both comparability and contextual relevance. It involves seven sites, around 100 co-creators, more than 40 co-creation sessions, and five trained facilitation agencies. A parallel randomised controlled trial will assess the co-created intervention's impact.

Methods: The co-creation approach is grounded in empowerment theory and critical realism, structured through the PRODUCES framework and evaluated with the recently published PROSECO evaluative co-creation framework. Co-creation will take place in the United Kingdom, France, the Netherlands, Denmark, Belgium, Greece, and Romania with children (8–10 years), adolescents (14–16 years), and adults (parents, teachers, youth and health professionals). Qualitative data will be generated through participatory activities, transcripts, and facilitator reflections and analysed thematically. Mixed methods will assess process quality, inclusiveness, and behavioural alignment.

Results: Findings will address the standard co-creation protocol designed, the procedure of the local adaptation, include useful and practical co-creation outputs, and describe how co-created content aligns with behavioural outcomes. The evaluation will describe useful, replicable metrics for an in-depth analysis of the co-creation process, including recommendations for quantitative analyses (baseline and post-co-creation measures) and qualitative analysis, presenting easy-to-use templates for researchers and practitioners.

Conclusion: This study provides insights, useful recommendations and practical outputs on how to apply large-scale, structured co-creation to behavioural nutrition and physical activity interventions. By embedding youth and stakeholder input across multiple countries, the protocol aims to support the replication of co-created digital interventions, advancing, this way, evidence-based co-creation practice in behavioural research.

S.3.55-1

Understanding and Optimising the Potential of Meal Kits as an Innovative Strategy to Promote Healthy Eating and Food Literacy

K. Fraser¹, P. Love², B. Johnson³, K.J Campbell², A. Spence²

¹Deakin University, Faculty of Health, School of Exercise and Nutrition Sciences, Melbourne, Australia, ²Deakin University, Institute for Physical Activity and Nutrition, School of Exercise and Nutrition Sciences, Melbourne, Australia, ³Flinders University, Caring Futures Institute, College of Nursing and Health Sciences, Adelaide, Australia

S.3.55 Socio-economic inequalities: Meal boxes as an innovative strategy to promote healthy and equitable food practices in families: from potential to practice

Multipurpose Room, May 30, 2026, 8:00 AM - 9:00 AM

Purpose: Nutrition interventions aim to improve family diet quality, particularly among vulnerable/low-income populations. These vary in approach, delivery format and strategies to support healthy eating and build food literacy (i.e. food-related knowledge, skills and behaviours). Meal kits (i.e. boxes of pre-portioned ingredients and recipes) are emerging as an innovative strategy to support healthy eating within the home environment. However, despite growing interest in meal kits, there is limited understanding of the mechanisms through which they may influence behaviour, or how their potential can be optimised. This research explored how and why commercial Australian meal kit services influence food literacy and identified opportunities for enhancing their behaviour change potential.

Methods: A one-week subscription was purchased for all Australian meal kit services (n=9) to access websites, meal kits and recipe databases. The Behaviour Change Technique Taxonomy (BCTTv1) and Theoretical Domains Framework (TDF) were systematically applied to meal kit content to assess their theoretical potential for promoting food literacy-

related behaviour change. Twenty-five parents of children (2-5 years) were interviewed to explore how families use commercial meal kits. Interview transcripts were coded using inductive thematic analysis then mapped deductively to a food literacy framework to identify if and how food literacy is supported.

Results: Twelve unique behaviour change techniques (BCTs) were identified within the meal kit component (i.e. ingredients and recipes), mapping to nine of the 14 TDF domains and targeting food literacy-related capability, opportunity and motivation. This suggests that the delivery of a meal kit may theoretically support food literacy development, though their impact may be limited without intentional design. Qualitative interviews revealed that commercial meal kits primarily support food literacy domains regarding 'planning and managing' and 'preparing', with less support of 'selecting' and 'eating'. This suggests that families may benefit from tailored support to maximise behaviour change potential of meal kits.

Conclusion: This research provides a theoretical understanding of the potential of meal kits as an innovative strategy to influence food literacy-related behaviours and improve family dietary quality. It offers practical recommendations to optimise the potential of meal kits through intentional design using behaviour change and food literacy frameworks.

S.3.55-2

Meal Boxes as an Innovative Intervention Strategy to Enable Healthy Food Choices and a Healthier Home Food Environment among Low-SES Families

H. Hoepman¹, A. Van Kerckhove¹, B. Deforche¹, W. Van Lippevelde¹

¹Ghent University, Ghent, Belgium

S.3.55 Socio-economic inequalities: Meal boxes as an innovative strategy to promote healthy and equitable food practices in families: from potential to practice

Multipurpose Room, May 30, 2026, 8:00 AM - 9:00 AM

Purpose: Families from a lower socioeconomic status (SES) often face barriers to cooking at home and their **food parenting practices** are less supportive of a healthy lifestyle compared to families with a higher SES. **Meal boxes** have the potential to help overcome barriers (e.g., time scarcity, lack of meal preparation knowledge) to cook at home and eat together. **Yet, in their current format they are not affordable or accessible for low-SES families.**

This study aims **to examine the needs, preferences, and acceptability of meal boxes among low-SES families.** To our knowledge, few studies have investigated their potential for low-SES families.

Methods: **Focus groups** were conducted with **low-SES parents of 6–12-year-olds in Belgium** to explore, for example, preferred meal offer, and willingness to pay for meal boxes. A subsample of these families **tested meal boxes** from different suppliers for one week. Participants ordered the meal box during a **Think Aloud interview**, capturing their decision-making processes and interaction with the interface. A **follow-up individual interview** assessed acceptability of the offer and potential impact on food parenting practices. This **stepwise approach** enabled broader discussions during the focus groups while providing in-depth insights on meal box usage in the individual interviews. All interviews were audiotaped and transcribed. A qualitative thematic analysis was conducted using MAXQDA.

Results: Preliminary results indicate that price is a main barrier for low-SES families to use meal boxes, although some perceived them as financially beneficial by reducing impulsive purchases. Participants appreciated discovering new recipes, and several reported that children became more involved in cooking and were therefore less picky. However, cultural preferences, limited flexibility, and concerns about portion sizes reduced acceptance.

Conclusion: Future strategies should focus on affordability, a diverse offer, and room for alterations. This needs assessment will inform the **co-development of healthy meal boxes** with commercial suppliers to better meet the needs of low-SES families. The adapted meal boxes will be evaluated in an **intervention study** assessing their effectiveness in improving healthy food choices. As such, this research aims to contribute to behavioral nutrition by addressing dietary inequalities and potentially suggesting sustainable strategies to improve health.

S.3.55-3

Can Recipe-boxes Improve Dietary Quality and Food Agency? Analysis of the Feasibility and Acceptability of a Pilot Randomised Controlled Trial in Households with School-aged Children

N. Cooke¹, J. Prabhu², J. Adams¹, M. White¹

¹IMS Epidemiology Unit, University of Cambridge, School of Clinical Medicine, Cambridge, United Kingdom, ²University of Cambridge, Judge Business School, Cambridge, United Kingdom

S.3.55 Socio-economic inequalities: Meal boxes as an innovative strategy to promote healthy and equitable food practices in families: from potential to practice

Multipurpose Room, May 30, 2026, 8:00 AM - 9:00 AM

Purpose: Recipe box subscriptions are a promising intervention to improve dietary quality by enabling the preparation of meals at home, which is associated with higher dietary quality. Partnering with a Recipe Box Company, we conducted an unblinded pilot and feasibility randomised waitlist-controlled trial of a discounted recipe box subscription. The subscription is discounted as commercial subscriptions are unaffordable for many. We aimed to test the feasibility and acceptability of the trial design and procedures for participants and researchers.

Methods: We recruited primary food providers in households with school-aged children, in Birmingham, UK, via five channels: social media, schools, employers, community organisations, and referrals from customers of the Company. Upon consenting, participants completed online questionnaires and 24-hour dietary recalls. The intervention consisted of a 6-week recipe box subscription, discounted by 60% in week 1 and 50% in weeks 2 to 6, with the option to continue ordering at a 20% discount in weeks 7-10. Control participants were offered the same intervention 10 weeks post-randomisation. Subsamples of participants from both groups were invited for qualitative interviews at baseline and during weeks 7-9.

Results: We randomised n = 165 participants into intervention (n = 84) or waitlist control (n = 81) groups. Data was collected from n = 128 at 6 weeks and n = 119 at 10 weeks. Data cleaning and preparation are in progress and analysis will be completed by March 2026. We will present findings on the acceptability and feasibility of recruitment methods and enrolment procedures, the recipe box subscription, and allocation to both groups, from mixed methods analyses, including thematic analyses of semi-structured interviews.

Conclusion: This is the first study to evaluate the feasibility and acceptability of a commercial recipe box intervention. This platform offers participants choice and flexibility and could support rapid scale-up. Our findings will inform progression to an effectiveness study, as well as offer the potential for future trials of recipe-box interventions on prescription for key clinical groups (e.g. people living with pre-diabetes or obesity).

S.3.56-1

Food Is the Best Medicine (FBM) for Food-insecure Postpartum Women: Findings from a Multi-arm Randomized Study

A. van den Berg¹, A. Nielsen¹, E. Polinard², V. Threadgould³, C. Reyes¹, A. Falzone⁴, A. Abel⁵, A. Fischweicher⁵, J. Chevalier⁶, N. Ranjit¹, D. Hoelscher¹

¹UTHealth Houston School of Public Health, Health Promotion and Behavioral Sciences, Austin, United States, ²Ascension Seton Medical Center, Austin, United States, ³Ascension Seton Foundation, Austin, United States, ⁴UTHealth Houston School of Public Health, Epidemiology, Austin, United States, ⁵Farmshare Austin, Austin, United States, ⁶CooksNook, Austin, United States

S.3.56 Socio-economic inequalities: Food as Medicine in Maternal Health: Advancing Nutrition Equity Across the Perinatal Continuum

Multipurpose Room, May 30, 2026, 10:00 AM - 11:00 AM

Purpose: For women experiencing food insecurity, the postpartum period after childbirth poses especially significant health challenges, including increased risk of inadequate nutrition, postpartum depression, and lower breastfeeding rates. Food is the Best Medicine (FBM) was developed to alleviate postpartum stress among food-insecure mothers by providing food assistance and behavioral support. The purpose of this presentation is to present results from a randomized controlled trial comparing three versions of the FBM intervention, each providing

8 weeks of home-delivered food boxes containing prepared meals, meal kits, organic produce, and staple foods: (1) FBM-Standard, which provided only the food boxes; (2) FBM-CHW, which included the food boxes plus two home visits from community health workers (CHWs) who assisted families in goal setting, community resources, home cooking, and enrollment in assistance programs; and (3) FBM-Virtual, which included food boxes plus access to a study-created website offering nutrition education, recipes, and community resource information.

Methods: 150 postpartum women were randomly assigned to one of the three intervention arms: FBM-Standard (n=45), FBM-CHW (n=49), and FBM-Virtual (n=56). Data were collected at baseline (T0), and immediately post-intervention (T1). Primary outcomes included food security, fruit and vegetable (F&V) and whole grain consumption, postpartum depression, food preparation practices, and financial stress. Differences in change over time between treatment groups were assessed using regression models with interaction terms between time and treatment group. Linear regression was used for continuous outcomes and logistic regression for binary outcomes. P-value was set at 0.05.

Results: Participants were primarily Hispanic (71%), low income (84% with household income of less than \$25,000), and had limited formal education (37% less than high school). Baseline socio-demographic and outcome data showed no significant differences among the 3 groups, except income level. Results demonstrated significant improvements in food security ($p < .001$) and vegetable and whole grain consumption ($p < 0.05$) from T0 to T1 among all three groups. No significant differences among the three groups were found.

Conclusion: Results indicate that different versions of FBM programs can improve food security and diet quality among food-insecure postpartum women. More research is warranted to determine the most meaningful way of incorporating CHW support into FIM interventions.

S.3.56-2

Randomized Controlled Trial Assessing the Impact of Technology-based Engagement Strategies to Improve Adoption of Medically-tailored Retail Produce Prescriptions

S. Sharma¹, R. Ridberg², N. Tice¹, A. Shyevitch³, J. Fernelius⁴, J.-M. Yamal⁵, R.-J. Chuang¹

S.3.56 Socio-economic inequalities: Food as Medicine in Maternal Health: Advancing Nutrition Equity Across the Perinatal Continuum

Multipurpose Room, May 30, 2026, 10:00 AM - 11:00 AM

Purpose: Produce Prescription (PRx) are increasingly part of an individual's treatment plan but evidence demonstrates funds for healthy foods are often underutilized. Delays in the first months of the program – especially enrollment, activation, and first transactions effectively reduce program length and potential impact. Fresh Connect, a PRx product of the non-profit organization About Fresh, Inc., consists of a pre-paid, programmable debit card and a cloud-based cardholder success platform. Active cardholders redeemed an average of 65-73% of their \$100-\$120 monthly benefits. It remains unclear the obstacles in the way of higher redemption rates. Our study question was - Does high-touch cardholder engagement, specifically weekly text messaging, increase PRx benefits utilization in Medicaid members with high-risk pregnancy in Houston, TX?

Methods: We randomized 103 study participants 1:1 to receive enhanced engagement communication using text messaging (intervention group) from Fresh Connect or usual care Fresh Connect cardholder engagement. All women receive the \$100/month benefits starting enrollment (<20 weeks gestation) for 3 months to use for purchasing fresh fruits/veg at grocery retail (no roll over). Three constructs were operationalized in the weekly enhanced text messaging - loss aversion, positive reinforcement and endowment framing. The primary outcomes measured include: (1) number of days from enrollment to first shopping transaction, (2) number of shopping transactions per month, (3) prescription dollar spend per month, and (4) proportion of benefits redemption per month. We will assess changes in food security, nutrition security and fruit and vegetable consumption from baseline to 3 months across both study arms.

Results: We have completed enrollment and baseline data collection as of November 2025. Final analysis of the RCT will be complete by March 2026 which will be presented at ISBNPA 2026. At baseline, for the 103 participants, the average age was 30 years, with racial distribution of 31% Black, 43% White and ethnically 56% were Hispanic. Median gestational age was 13 weeks at the time of enrollment. Overall activation rate for the About Fresh card was 72% and

SYMPOSIUM

redemption rate was 92%.

Conclusion: As PRx program designs have matured there are increased opportunities for improved program implementation outcomes which will be demonstrated in our study.

S.3.56-3

Designing Inclusive and User-centered Nutrition Interventions for Gestational Diabetes Prevention

K. Hollis-Hansen¹, S. van den Berg², N. Ranjit², J.-M. Yamal³, N. Tice⁴, A. Nielsen², S. Sharma⁴

¹Tufts University, Food is Medicine Institute, Boston, United States, ²UT Health Houston, Health Promotion & Behavioral Sciences, Austin, United States, ³UT Health Houston, Biostatistics, Austin, United States, ⁴UT Health Houston, Epidemiology, Houston, United States

S.3.56 Socio-economic inequalities: Food as Medicine in Maternal Health: Advancing Nutrition Equity Across the Perinatal Continuum

Multipurpose Room, May 30, 2026, 10:00 AM - 11:00 AM

Purpose: Gestational diabetes mellitus (GDM), the most common medical complication of pregnancy, poses significant risks to maternal and infant health, including hypertensive disorders, cesarean delivery, and long-term development of type 2 diabetes and cardiovascular disease. GDM also has intergenerational consequences, increasing children's risk for macrosomia, metabolic disorders, and diabetes. With GDM prevalence rising, innovative prevention strategies are urgently needed, particularly for populations disproportionately affected, such as women living with lower income in rural communities and racially and ethnically minoritized groups.

Methods: This user-centered design (UCD) pilot study aims to develop a comprehensive protocol for a future large-scale multisite trial, the Medically-tailored nutrition intervention to Achieve Nutrition security and improve Gestational Outcomes (MANGO) study. The target population includes Medicaid-eligible women at-risk for GDM. Exclusion criteria include pre-existing diabetes, hemoglobin A1c ≥ 7 , or current insulin/metformin use. Eligible women are provided a bi-weekly home-delivered Food is Medicine (FIM) box. The content of each box varies but includes a combination of medically tailored groceries (MTG), produce prescriptions (PRx), and nutritious meal kits. Digital nutrition and support from dietitians are available to all participants as desired. Baseline and follow-up questionnaires as well as bi-weekly satisfaction surveys, and qualitative interviews will be used to identify preferred FIM box contents, adherence, usability, perceived effectiveness, cultural appropriateness, program satisfaction, and future opportunities for program improvement.

Results: Three community sites, 1) a safety-net health center serving Hispanic and/or Latino(a) women in Austin, Texas, 2) a safety-net health center serving predominantly African American or Black and white pregnant women in Massachusetts, and 3) a health system in Maine that predominantly serves pregnant women living in rural communities are approved to begin data collection and collection will be completed by March of 2026.

Conclusion: This presentation informs on how UCD design principles can be used to develop patient-centered interventions. The results of this study will be used to design a full-scale RCT for a major funding agency, contributing to the evidence base for scalable, equity-focused nutrition interventions in prenatal care.

Participation in an Online Nutrition Education Program Did Not Improve Physical Function in Community-dwelling Older Adults

Z. Yin¹, V. Sherma², E. Sosa¹, M. He¹, M. Martinez², T. Zhang³, S. Ullevig²

¹University of Texas at San Antonio, Public Health, San Antonio, United States, ²University of Texas at San Antonio, Nutrition and Dietetics Program, San Antonio, United States, ³University of the Pacific, Health and Exercise Sciences, Stockton, United States

Purpose: Decline in physical function (PF) is predictive of disability, quality of life, and mortality in older adults. This study investigated the effect of an online nutrition education program on PF in older adults in a clustered randomized controlled trial. The study hypothesis was that the participants in the online nutrition education program had a higher PF level than the participants in the control condition.

Methods: Study participants were community-dwelling adults aged 60+ years enrolled in 14 congregate meals program sites in South Texas, the United States of America (USA). The program sites were randomly assigned to a 6-month online nutrition education intervention or control treatment. The nutrition education program focused on digital literacy and evidence-based nutrition knowledge and practices. Data for this study were collected at the baseline and posttest assessment of the 6-month intervention. PF was assessed by the Short Physical Performance Battery (SPPB) consisted of the chair-stand test, gait speed test, and balance test. Other measures included the Dietary Screener Questionnaire (DSQ), the body mass index (BMI), and a demographic and health history survey. A linear mixed model was used to examine the difference in SPPB total score between the treatment groups at the 6-month posttest, controlling for the nesting effect by the program sites, baseline DSQ score, baseline BMI, and demographic variables.

Results: The participants (n=352, mean age= 72.1 (SD 6.55) were 78% females; 13% Black, 60% Latino; 19% White, 9% others; 48% with ≤high school education; 50% with household income ≤US\$20,000/year. Mean SPPB total score was 7.42 (2.26) with 7.92 (2.17) for males and 7.29 (2.27) for females at baseline. Results of mixed model analysis showed a marginally significant improvement in SPPB total scores over time ($\beta = 0.26$, 95% CI [-0.01, 0.53], $p = 0.059$). There was no significant difference between treatment groups ($\beta = 0.07$, 95% CI [-1.19, 1.33], n.s.), and the interaction between treatment groups and time was not significant ($\beta = -0.08$, 95% CI [-0.48, 0.34], n.s.), suggesting both treatment groups improved.

Conclusion: An evidence-based nutrition education program without environmental and policy modification did not improve PF in older community-dwelling adults.

I-P-A.04

Characterizing 24-hour Movement Behaviors among Low-income Mexican-American Adults with Uncontrolled Type 2 Diabetes: Preliminary Results from the Salud y Vida Accelerometry Study

C. Pfladderer¹, M. Kapfhammer¹, K. Reininger², J. Lopez³, L. Bennett³, J. McCormick³, B. Reininger³

¹University of Texas Health Science Center Houston, Austin, United States, ²University of Texas at Austin, Austin, United States, ³University of Texas Health Science Center Houston, Brownsville, United States

Purpose: The purpose of this study was to characterize the baseline 24-hour movement behavior profiles (steps, light physical activity [LPA], moderate physical activity [MPA], vigorous physical activity [VPA], inactivity, and sleep duration) of low-income Mexican-American adults with uncontrolled type 2 diabetes who enrolled in the Salud y Vida intervention to improve HbA1c control. This population is understudied in 24-hour movement behavior research.

Methods: Within this 18-month repeated measure intervention study that examines clinical, behavioral, and multi-omic markers, participants were instructed at baseline to wear an accelerometer (Axivity AX3) on their non-dominant wrist for 24 hours/day across a 10-day wear period. Accelerometry data were processed using the GGIR package in R using validated cut-points and algorithms to determine intensity thresholds and sleep duration. A valid wear day was defined as a minimum of 16 hours. Descriptive means and standard deviations were calculated for all device-assessed movement behavior variables, including steps, LPA, MPA, VPA, inactivity, and sleep duration.

Results: A total of 44 participants (54.8 ± 9.1 years, 82% female, 98% Hispanic/Latino, 91% with household income of \$29,999 or less) were included in the analytical sample. On average, participants had 7 ± 2 days of valid accelerometry data and 4 ± 6% of non-wear time over the course of the measurement period. When averaging movement behaviors

A. AGEING

across the 10-day baseline wear period, participants accrued $6,393 \pm 1497$ steps/day, 156 ± 81 minutes/day of LPA, 32 ± 31 minutes/day of MPA, 0.06 ± 0.20 minutes/day of VPA, 14 ± 2 hours/day of inactivity, and 6 ± 2 hours/night of sleep.

Conclusion: Preliminary evidence suggests the 24-hour movement behavior profile of low-income Mexican-American adults with uncontrolled Type 2 diabetes who participated in the Salud y Vida accelerometry study is characterized by a moderate amount of steps, LPA, and MPA, a high amount of inactivity, and a low amount of VPA and sleep. Programs/interventions designed for this population should focus on shifting movement to higher intensities, replacing inactivity with activity, and improving sleep duration.

I-P-A.05

Comparing Food Insecurity and Nutrition Insecurity Prevalence among Older Adults Participating in Meals on Wheels and the Connection with Diet Quality

K. Gans¹, I. Costa da Silva¹, M. Grady², K. Thomas³, G. Oladeji¹, M. Noonan¹, B. Tyler¹, S. DeFelice², M. Hussein², A. Lusi², K. Ramos-Morales², C. Caspi¹

¹University of Connecticut, Storrs, United States, ²Meals on Wheels of Rhode Island, Providence, United States, ³Johns Hopkins School of Nursing, Baltimore, United States

Purpose: Food insecurity (FI) and nutrition insecurity (NI) are related but distinct concepts. FI is the lack of consistent access to enough food, while NI also includes having consistent access to foods that promote health and prevent diet-related diseases. Measuring NI is newer and more complex but has less evidence when compared to FI measures. A new Nutrition Security Screener (NSS) has recently been validated, but there is a need to measure its performance in population subgroups including older adults, who may experience different food access barriers than younger adults.

Methods: Older adults (≥ 60 years) participating in the Meals+ study at Meals on Wheels of Rhode Island completed baseline measures including FI (6-item Household Food Security Scale -HFSS), and NI (2-item NSS), which also assesses the prevalence of 13 barriers to NI. We compared the prevalence of NI and FI in this population and assessed diet quality scores using the 25-item Dietary Screening Tool (DST).

Results: Recruitment is ongoing; as of 11/07/2025, 100 participants (61.7% female, average age 71.9 ± 7.3 years) completed both HFSS and NSS. Overall, we observed a high prevalence of both FI (59.0%) and NI (72.0%). We observed concordance between FI and NI status in 65.0% of participants, with 11.0% classified as FI only and 24.0% NI only. The most common barriers for those facing NI were mobility/physical limitations to prepare healthier meals (84.0%), lack of transportation (77.8%), and price of healthy food (74.0%). Participants classified as FI and NI had a mean DST score of 50.7 ± 12.6 , with 75.0% at high nutritional risk, compared to a mean DST score of 63.9 ± 11.9 , with 29.4% at high nutritional risk among those without FI or NI. *Note: Recruitment continues through 2026, so more data will be added before the conference presentation.*

Conclusion: In a study among older adults, FI and NI measures had good concordance, with NI higher than FI, as expected. Participants with FI and NI had lower diet quality when compared with FI or NI only groups. Some barriers to nutrition security for older adults differed from younger populations, highlighting the need to tailor nutrition interventions for this population.

I-P-A.06

Evaluating the Effectiveness of an Mhealth Application to Promote Home-based Exercise in Adults Aged 65 and Older: A Single Group Study Protocol

K. Quadflieg¹, J. Robijns¹, K. Daniels¹

¹PXL University of Applied Sciences and Arts, Healthcare, Hasselt, Belgium

Purpose: With the global population aging rapidly, older adults face increased risks of physical and cognitive decline. Despite the well-documented benefits of physical activity (PA), many older adults fail to meet PA guidelines. Mobile health (mHealth) applications offer promising tools to promote PA, but engagement remains a challenge. The MIA (More in Action) app was co-created with older adults using the Behavior Change Wheel framework to enhance usability, relevance, and sustained engagement. A feasibility study indicated promising usability and satisfaction, supporting further evaluation. This study aims to evaluate the effectiveness of MIA in promoting PA among older adults.

A. AGEING

Methods: A prospective single-group trial will evaluate the MIA app over an eight-week period. The primary outcome is moderate-to-vigorous physical activity (MVPA) measured using Garmin wearable devices. Secondary outcomes include self-reported PA, well-being, user satisfaction, clinical assessments (physical and cognitive functioning), and daily step count. A total of forty participants will be recruited. Eligible participants are ≥ 65 years, medically stable, with no significant cognitive or physical limitations, Dutch-speaking, and with smartphone or computer access. Exclusion criteria include engaging in an already active lifestyle (>150 min MVPA per week), participation in other exercise programs or trials, or conditions compromising safety or study validity. Changes from baseline to post-intervention will be analysed using paired-samples t-tests or non-parametric tests. Statistical significance will be set at $p < 0.05$, analyzed with IBM SPSS Statistics.

The innovation of this study lies in evaluating the effectiveness of a co-created, theory-driven mHealth intervention for older adults. By combining objective activity tracking with self-reported and clinical outcomes, it offers a comprehensive assessment of intervention impact. The findings will contribute to the growing evidence on mHealth effectiveness and will inform whether a co-created, theory-based app can support sustained PA in aging populations.

Results: Recruitment for the study commenced on October 7th, 2025. Data collection is ongoing.

Conclusion: This study will generate evidence on the potential of co-created, theory-driven mHealth interventions to promote PA in older adults. It will guide strategies to enhance engagement, inform future digital health design, and advance behavioral PA research and evidence-based practice.

I-P-A.07

ENERGY Study Protocol: Efficacy of a Program Combining Exercise, Nutrition, and Psychological Support in Patients Aged ≥ 70 Years Enrolled in Early-phase Clinical Trials

B. Fournier¹, F. Scotté², M. Frélaud³, P. Funk-Debles⁴, J.-B. Le Provost², G. Martinez⁵, R. Mongondry¹, K. Ouali⁵, A. Pages⁶, G. Paillard-Brunet⁴, B. Raynard², P. Roux⁴, C. Russo⁷, C. Terret⁷, O. Pérol¹, C. Baldini⁵

¹Centre Léon Bérard, Département Prévention Cancer Environnement, Lyon, France, ²Gustave Roussy, Département Interdisciplinaire d'Organisation du Parcours Patient, Villejuif, France, ³Gustave Roussy, Département de Médecine Oncologique, Villejuif, France, ⁴Centre Léon Bérard, Département Interdisciplinaire de Soins de Support en Oncologie, Lyon, France, ⁵Gustave Roussy, Département d'Innovation Thérapeutique et d'Essais Précoces, Villejuif, France, ⁶Gustave Roussy, Direction de la Recherche Clinique, Villejuif, France, ⁷Centre Léon Bérard, Département de Cancérologie Médicale, Lyon, France

Purpose: The primary objective of the ENERGY study is to evaluate whether a multimodal intervention combining exercise, nutritional management, and psychological support can improve inclusion and retention rates of cancer patients aged ≥ 70 years in early-phase (phase I) clinical trials. We hypothesize that improving physical function, nutritional status, and psychological resilience will enhance eligibility for and adherence to experimental treatments. This study is innovative in its patient-centered approach, integrating three complementary interventions within early-phase oncology to promote more equitable access to and benefit from phase I trials for older adults who remain largely underrepresented.

Methods: The ENERGY trial consists of two sequential phases. The first is a pilot study assessing the feasibility of the multimodal intervention in 10 patients. The second phase is an open-label, randomized (1:1), multicenter controlled trial comparing the intervention group with standard care across 10 French centers accredited for early-phase oncology trials. A total of 196 patients aged ≥ 70 years, treated for cancer and enrolled in a phase I clinical trial, will be included. Participants will undergo physical, nutritional, and psychological assessments at baseline and at 1, 2, and 3 months. The intervention group will receive a 3-month combined program of exercise, nutritional management, and psychological support, the specific modalities of which will be refined through input from former patients and caregivers during the pilot phase. The control group will receive standard care. Statistical analyses will assess whether the multimodal program improves inclusion and retention in our study population, as well as its effects on physical capacities, physical activity level and motivation, nutritional status, body composition, mood, quality of life, toxicities, healthcare use, and—within the intervention group—program adherence and fidelity, population reach, and barriers, facilitators, and satisfaction among patients, caregivers, and professionals.

Results: As recruitment has not yet started, this presentation will focus on the study protocol.

Conclusion: By integrating exercise, nutrition, and psychological support, the ENERGY project could redefine phase I care pathways and improve both the inclusion of older adults with cancer and their ability to benefit optimally from experimental treatments.

A. AGEING

I-P-A.09

Mental Fatigue Impairs Physical Performance in Healthy Active Women Aged over 65 Years

J. Díaz-García¹, A. Rubio-Morales¹, R. Ayuso-Moreno¹, T. García-Calvo¹

¹Faculty of Sport Sciences, University of Extremadura, Caceres, Spain

Purpose: The main study purpose was to evaluate the effects of 20 min. sustained cognitive activity on the physical performance of healthy active women aged over 65 years. Mental fatigue has been shown to impair physical performance across the lifespan, however recent evidence suggests that these detrimental effects may be exacerbated with aging. To our knowledge, this is the first study to investigate the effects of mental fatigue in this specific population. Our findings may improve understanding of how everyday mental fatigue impacts training performance and associated health benefits in older women, a population for whom physical activity plays a key role for health.

Methods: Forty healthy - physically active (confirmed by International Physical Activity Questionnaire) women aged over 65 years participated in a randomized crossover design. After a familiarization session, participants completed two testing sessions in a randomized counterbalanced order where their physical performance (6-minute walk, 30-second sit-to-stand, handgrip strength, and Timed Up and Go) were tested before and after two different experimental conditions: (1) **Fresh** – 20 min. watching a neutral documentary, or (2) **Mental Fatigue** – 20 min. engaging the Time Load Dual Back Task (TLDB). Performance outcomes were compared between conditions to determine the effects of mental fatigue.

Results: Subjective fatigue ratings and cognitive performance (TLDB) confirmed successful induction of mental fatigue. Handgrip strength and Timed Up and Go performance were not affected by mental fatigue. In contrast, the number of repetitions in the 30-second sit-to-stand test ($p = 0.03$) and the distance covered during the 6-minute walk test ($p = 0.01$) were significantly reduced under the mental fatigue condition, with no changes observed in the Fresh condition. These impairments were accompanied by significantly higher ratings of perceived physical exertion ($p = 0.01$) in the mental fatigue session.

Conclusion: Mental fatigue induced by sustained cognitive activity negatively affects strength-endurance and endurance performance in healthy-physically active women aged over 65 years, while maximal strength and short-duration agility remain preserved. These findings suggest that mental fatigue may compromise training outcomes and, subsequently, attenuate the health-associated benefits of exercise in this population. These findings highlighting the importance of considering mental fatigue in older women.

I-P-A.10

Study Design for Realworld Assessment of Physical Activity, Behaviour, and Heat-related Strain in Older Adults during Heatwaves

G. Bourgois¹, J.G. Bourgois¹, G. Cardon¹

¹Ghent University, Department of Movement & Sports Sciences, Ghent, Belgium

Purpose: Background: Older adults are disproportionately vulnerable to heat-related morbidity, yet little is known about how they behave and adapt their daily routines during heatwaves in their natural environments. Existing laboratory studies provide mechanistic insight into thermoregulatory strain, but they cannot capture the environmental, behavioural and psychosocial factors that shape real-world heat exposure. In daily life, individual heat vulnerability results from an interaction between intrinsic biological factors, physical activity patterns, sleep, indoor/outdoor microclimates, and behavioural responses. Understanding these interactions is essential as heatwaves are projected to become longer, hotter, and more frequent, posing direct challenges to healthy aging, active lifestyles and climate resilience.

Purpose: This ecological study aims to determine how older adults perceive and respond to heat in their daily lives, with a specific focus on changes in physical activity behaviour, sleep, psychological wellbeing, and self-selected heatmitigation strategies during heatwaves.

Methods: A prospective, withinsubject observational study will be conducted across two periods: a “control” phase (April–May) and a Belgian heatwave phase (i.e., ≥ 5 consecutive days $>25^{\circ}\text{C}$, including ≥ 3 consecutive days $>30^{\circ}\text{C}$). One hundred older adults (balanced by sex) will complete both periods. Participants will use wearable sensors for continuous monitoring of heart rate, physical activity patterns and sleep. Environmental data loggers in the living room and bedroom will assess indoor heat exposure, in combination with outdoor weather stations. With use of

A. AGEING

digital questionnaires thermal perception, mitigation behaviours (e.g., hydration, activity timing, shade use) and psychological state will be evaluated. Linear mixed-effects models will be used to assess differences between conditions and to quantify associations between physical activity, behavioural factors, environmental conditions, and heat-related strain.

Results: Expected Outcomes: We hypothesize that heatwave exposure will reduce daily physical activity, alter activity timing, impair sleep, and increase perceived and physiological strain. Indoor temperatures are expected to influence heat strain and correlate strongly with behavioural adaptations. This research will provide actionable evidence for policymakers and health agencies. It will identify behavioural and environmental conditions that support heat resilience in older adults, informing targeted interventions that safeguard physical activity, autonomy, and wellbeing in a warming climate.

Conclusion: /

I-P-A.11

Dietary Intake and Nutritional Biomarker Status in Relation to Appetite Loss and Physical Activity in Older Adults

A. Turesson¹, P. De Souto Barreto^{2,3}, M. Nydahl¹, A. Koochek¹

¹Uppsala University, Food Studies, Nutrition and Dietetics, Uppsala, Sweden, ²Toulouse University Hospital (CHU Toulouse), Institute On Aging, Toulouse, France, ³University of Toulouse, CERPOP UMR 1295, INSERM, UPS, Toulouse, France

Purpose: Although appetite loss is associated with malnutrition, differences in dietary intake and nutritional biomarker status between older adults with and without appetite loss remain unclear. The potential moderating role of physical activity has also been insufficiently studied.

This study aims to examine differences and associations between appetite loss, dietary intake, and nutritional biomarker status (e.g., serum vitamins and minerals) in older adults. A secondary aim is to determine whether physical activity modifies these associations.

We hypothesize that older adults with appetite loss will have lower energy and nutrient intakes and poorer nutritional status than those without appetite loss. We further expect that higher physical activity levels will attenuate the negative association between appetite loss and nutrient status. The study is ongoing and preliminary findings will be presented at the conference.

Methods: This cross-sectional study will utilize data from the Swedish aging cohorts H70 (n ≈1000) and SNAC-K (n ≈3000). Participants aged ≥65 years with available data on appetite, physical activity, dietary intake, nutritional biomarker status, and relevant covariates will be included. Descriptive statistics and multivariable regression models will be assessed. Appetite status at baseline (poor vs. normal appetite) is the exposure, and dietary intake and nutritional biomarker status are the primary outcomes. Models will be adjusted for key covariates, including socioeconomic factors, smoking status, cognition, diseases, living situation, age, sex, civil status, body composition, and total energy intake (for nutrient intake).

Results: Analyses will examine (1) differences in dietary intake and nutritional biomarker status (i.e., serum vitamin and minerals) between older adults with and without appetite loss, (2) associations between appetite loss, dietary intake and nutritional biomarker status, and (3) the potential modifying effect of physical activity on these associations.

Conclusion: This study will contribute to understanding how appetite loss influences dietary intake and nutritional biomarker status in older adults, and whether physical activity may modify these effects. Furthermore, this study may provide new insights into appetite loss among older adults and inform targeted interventions and public health strategies to support appetite, promote healthy aging, and improve nutritional outcomes.

I-P-A.12

Knowledge, Perceptions, and Behaviours towards Muscle Strengthening Activities in Community Dwelling Older Adults: A Data2Action Survey Study

O. Soontjens¹, D. Van Dyck¹, S. Chastin^{1,2}, G. Cardon¹

¹Ghent University, Movement and Sports Sciences, Ghent, Belgium, ²Glasgow Caledonian University, Allied Health Professions, Glasgow, United Kingdom

A. AGEING

Purpose: Muscle-strengthening activities (MSA) provide important health benefits for older adults. Despite WHO recommendations to perform MSA on two or more days per week, adherence is strikingly low, and MSA remains underrepresented in research and practice in comparison to aerobic physical activity. Limited understanding of what constitutes MSA and its associated guidelines has been identified as a potential barrier. Within the scope of the EU MSCA Data2Action doctoral network (101169037), this study examines community dwelling older adults' awareness and understanding of MSA and its guidelines, how they interpret what constitutes MSA, and how these perceptions and knowledge are related to their muscle-strengthening behaviour.

Methods: Belgian adults aged ≥ 65 years without diagnosed cognitive or physical impairment are included in this cross-sectional survey (33 items). The target number of respondents is 1,000 (February-May 2026). Measures include sociodemographic characteristics, innovative items assessing awareness, knowledge, and perceptions of MSA and its guidelines, activity-classification tasks, and validated items assessing self-reported muscle-strengthening behaviour. Motivators, barriers, and open-ended responses are also collected to contextualise behavioural engagement. A pilot study was conducted to ensure questionnaire reliability and coherence among participants. Descriptive statistics summarised pilot responses, and associations between knowledge accuracy and behaviour were examined. Planned analyses will further explore associations between knowledge, perceptions, and behaviour.

Results: Preliminary pilot findings showed high perceived importance of muscle health (97%) and belief in MSA benefits (93%). However, only 48% felt confident identifying MSA. Misclassification was common (66% identifying walking and 71% cycling as MSA). Although overall misinterpretation was evident, older adults participating in MSA (Yes /No) demonstrated significantly greater classification accuracy than non-participants (mean = 4.05 vs 1.75, $p = .011$). Knowledge of the official guidelines was also limited, with 42% believing MSA should be performed daily. Despite this inaccuracy, 71% reported that the presented WHO guidelines were clear.

Conclusion: Perceived clarity of MSA guidelines does not necessarily reflect accurate understanding. However, better conceptual understanding of MSA is associated with engagement in muscle-strengthening behaviour. Improving how MSA recommendations are communicated and understood may be key to supporting healthy ageing. Further findings from the main study will be presented at the conference.

I-P-A.13

Goal-setting and Walking in Older Persons with Multimorbidity: A Longitudinal Investigation

S. Harvey¹, I. Coklar-Okutkan², F. Teixeira², J. Dinsmore², J. Doyle¹

¹Dundalk Institute of Technology, NetwellCASALA, School of Health and Science, Dundalk, Ireland, ²Trinity College Dublin, Trinity Centre for Practice and Healthcare Innovation, School of Nursing and Midwifery, Dublin, Ireland

Purpose: Older persons with multimorbidity (PwMs) live with two or more chronic health conditions. Key to the management of multimorbidity is physical activity engagement. Previous research indicates that physical activity engagement, including walking, is associated with better health outcomes (e.g., physical and cognitive function) and reduced mortality in older adults in general and older PwMs especially. Previous research also suggests that goal-setting facilitates greater physical activity engagement in adults and older adults in general, albeit research has yet to explore this relationship in older PwMs. Thus, the objective of this study was to explore the relationship between goal-setting, implemented via an innovative digital health platform called ProACT, and walking in older PwMs.

Methods: The ProACT platform comprised health-related measuring devices (e.g., a weight scale, blood pressure monitor, and smartwatch) and an app (e.g., where one could monitor their symptom trends), designed to support older PwMs to manage their conditions. This platform was tested during an effectiveness-implementation hybrid trial with older PwMs in Ireland during a six-month period. A range of data was collected from 146 participants, including their step count per week and whether or not they set a steps goal.

Results: Multilevel negative binomial regression analysis revealed that those who set a goal walked significantly more during their first week of trial participation than those who did not ($\beta = 0.40$ [95% CI: 0.03, 0.78]). The former group retained their advantage throughout their trial periods, albeit their step count declined to a (non-statistically significant) greater extent ($\beta = -0.04$ [95% CI: -0.10, 0.01]).

Conclusion: These findings demonstrate that goal-setting via digital health technology may help older PwMs to walk more and thus better manage their conditions. Future research is needed to explore how goal-setting may facilitate sustained physical activity engagement over time. This study was conducted during the SEURO project (<https://seuro2020.eu>), funded by the EU's Horizon 2020 research and innovation programme under Grant Agreement number 945449. The lead author is also supported by CREATE-DkIT, which is co-funded by the Government of Ireland and the European Union through the ERDF Southern, Eastern & Midland Regional Programme 2021-27.

I-P-A.14

Self-reported Physical Activity and its Relationship with Sleep Quality and Mental Fatigability in Healthy Middle-aged Adults from Rural Areas: A Cross-sectional Study

J. Diaz-Garcia¹, D. Lobo-Triviño¹, I. Ramírez-Bravo², J.J. Pulido-González³

¹Faculty of Sport Sciences, University of Extremadura, Caceres, Spain, ²Universidad Europea de Madrid, Department of Sports Sciences, Faculty of Medicine, Health and Sports, Villaviciosa de Odón (Madrid), Spain, ³Faculty of Education and Psychology, Badajoz, Spain

Purpose: The study aimed to compare subjective sleep quality and perceived mental fatigability across different levels of self-reported physical activity, as classified by International Physical Activity Questionnaire (IPAQ) scores, in healthy middle-aged adults from rural areas. We hypothesized that individuals with higher physical activity levels would report better subjective sleep quality and lower perceived mental fatigability. These findings may help to clarify whether meeting physical activity recommendations is sufficient to benefit sleep and mental fatigability, or where more structured exercise programs are necessary in this population.

Methods: A cross-sectional survey design was employed: 359 healthy adults aged over 65 years from Extremadura participated in the study. Data were collected in a single assessment using validated self-report questionnaires. Physical activity levels were assessed using the IPAQ, and participants were classified as sedentary (n = 118), moderately active (n = 137), or active (n = 104) accordingly. Subjective sleep quality was evaluated using the Pittsburgh Sleep Quality Index (PSQI), and perceived mental fatigability was assessed using the mental fatigability subscale of the Pittsburgh Fatigability Scale. Sleep quality and mental fatigability outcomes were compared across physical activity groups to examine group differences associated with activity level.

Results: Significant between-group differences were observed for sleep-related variables ($p = 0.01$). Physically active participants reported significantly greater sleep duration and better subjective sleep quality compared with sedentary ($p = 0.01$) and moderately active groups ($p = 0.04$). In contrast, no significant differences were found between physical activity groups for perceived mental fatigability ($p = .36$). These findings indicate that higher levels of self-reported physical activity are associated with improved sleep quality, whereas mental fatigability may not be sufficiently influenced by habitual physical activity alone.

Conclusion: While being physically active appears to be sufficient to improve sleep in older adults from rural areas, more targeted interventions may be required to reduce perceived mental fatigability. Structured-individualized exercise programs or cognitive-based interventions, such as Brain endurance Training, may represent effective strategies to address mental fatigability. Given the limited availability of active aging programs in Extremadura and the association between mental fatigability and adverse health outcomes (e.g., falls), this issue warrants greater attention in public health policies.

I-P-A.15

Promoting Active Ageing through Social Prescribing: Insights from Flemish Healthcare Professionals

A. Botha¹, G. Cardon¹, D. Van Dyck¹, L. Maenhout¹, S. Chastin², S. Stegen¹

¹Ghent University, Department of Movement and Sports Sciences, Faculty of Medicine and Health Sciences, Gent, Belgium, ²Glasgow Caledonian University, Department of Allied Health Professions, Glasgow, United Kingdom

Purpose: Social prescribing is increasingly recognised as a promising approach to improve wellbeing and support active ageing among adults aged 65 and older. In Flanders, however, little is known about the behavioural factors that shape healthcare professionals' engagement in social prescribing, nor how digital tools may support this process. The study introduces a COMB-informed survey to examine the capability, opportunity, and motivation of first-line healthcare professionals to deliver social prescribing. The study additionally explores how professionals evaluate the usability and perceived potential of De Verenigingspil, a digital platform designed to facilitate referrals to community-based social initiatives for older adults.

Methods: A cross-sectional online survey will be administered to firstline healthcare professionals, including general practitioners, nurses, physiotherapists, pharmacists, social workers and movement coaches participating in monthly training sessions. The survey draws on validated components from ISABE, TDF, HABS, NoMAD, the Theoretical Framework of Acceptability, and the System Usability Scale (SUS). Items are organised according to the COMB model.

A. AGEING

Usability of De Verenigingspil is evaluated through SUS scoring and additional questions on perceived usefulness, relevance for older adults, and anticipated influence on future social prescribing behaviour. Open-ended questions capture barriers, enablers, and suggestions for platform improvement. Data will be analysed descriptively, with thematic mapping of barriers/enablers to COMB domains. SUS scores will be interpreted using established thresholds. Findings will be visualised in a COMB behavioural determinant map.

Results: Findings will describe participant characteristics and summarise levels of capability, motivation, and opportunity for social prescribing among healthcare professionals. Usability findings for De Verenigingspil will be reported using SUS scoring and perceived usefulness. A COM-B behavioural map will highlight key barriers and enablers, informing recommendations for future implementation and scale-up.

Conclusion: This presentation will provide foundational insight into behavioural determinants influencing social prescribing for older adults in Flanders, while informing optimisation and implementation potential of De Verenigingspil as a practice-support tool.

II-P-A.01

Walk On!: Implementation Considerations for a Community-based Walking Program for Older Adults with Mobility Impairments

T. Oniffrey¹, J. Hughes², J. Moore², E. Chmelo¹, B. Nicklas³

¹Atrium Health Wake Forest Baptist, Internal Medicine/Geriatric Medicine, Winston-Salem, United States, ²Wake Forest University School of Medicine, Department of Implementation Science, Winston-Salem, United States, ³Wake Forest University School of Medicine, Department of Internal Medicine, Section on Gerontology and Geriatric Medicine, Winston-Salem, United States

Purpose: Mobility impairments (conditions that limit a person's coordination, stability, balance, or ability to ambulate) among older adults are associated with decreased independence and increased health risks. Evidence-based, scalable interventions are needed to address these challenges in community settings. The purpose of this presentation is to describe the development, implementation, and outcomes of *Walk On!*, a community-based program designed for older adults with mobility limitations.

Methods: *Walk On!* was developed at Wake Forest University School of Medicine and expanded across multiple markets within the Advocate Health System, located in the southeastern United States. Guided by the Exploration, Preparation, Implementation, and Sustainment (EPIS) framework, the program was designed to require minimal resources and staffing. Implementation strategies focused on acceptability, appropriateness, and sustainability. The program emphasizes feasibility, affordability, and adaptability across diverse settings in the United States. Program sessions focus on long-distance walking, taking place in community-based organizations for one-hour per day, two days/week, over a 12-week timeframe. Evaluation included measures of functional improvement and participant satisfaction.

Results: Across multiple sites, *Walk On!* demonstrated significant improvements in physical functioning among participants and consistently high satisfaction ratings. The program was perceived as effective, acceptable, and appropriate for older adults with mobility impairments, as rated by participants and staff employed or volunteering at the local sites. Current efforts are focused on expanding implementation into rural and underserved communities, and scaling across the six states served by the Advocate Health System.

Conclusion: *Walk On!* represents a potentially scalable, low-cost intervention that improves mobility and quality of life for older adults. Its success highlights the value of implementation science frameworks in guiding dissemination and sustainment of community-based health programs.

II-P-A.02

Sedentary Time, Executive Function, and Spatial Ability in Older Adults: A Quasi-experimental Study

J. Copeland¹, D. Aguilar Ramirez², C. Gonzalez^{1,2}

¹University of Lethbridge, Kinesiology & Phys. Ed., Lethbridge, Canada, ²University of Lethbridge, Neuroscience, Lethbridge, Canada

Purpose: Although sedentary time (ST) has been linked to poorer cognitive outcomes in older adults, experimental evidence remains limited. This study tested whether an induced increase in ST leads to measurable changes in

A. AGEING

executive and visuospatial abilities and evaluated the feasibility of this protocol in an older population.

Methods: Using a quasi-experimental design, older adults completed either two weeks of their usual activities (Group 1: $N=18$; 44% men; 68.2 ± 5.5 years) or one week of usual activity followed by one week of increased ST (Group 2: $N=11$; 27% men; 67.6 ± 7.8 years). Each week, participants wore an activPAL™ inclinometer to quantify ST and completed a Stroop test (executive function), a paper-based Mental Rotation Test (MRT), and three hands-on visuospatial tasks: one visual search and two rotation tasks differing in spatial demand. Changes in cognition and movement were analyzed using mixed ANOVAs, and Pearson's r assessed correlations between cognitive and movement measures.

Results: Group 2 increased daily ST by 59 ± 57 minutes ($p < .05$), although only 8 of 11 participants achieved this and only 3 of 11 met the step target (<3000 per day) for Week 2. They performed worse on the visual search task than Group 1 ($p = .035$). No significant group $\times$ time interaction emerged for any cognitive measure, but there was a trend for poorer visuospatial performance in Group 2 after Week 2 ($p = .086$). Among all participants, across weeks, higher ST correlated with lower spatial task performance ($r = .459$, $p < .02$). After Week 2, higher ST was associated with slower visual search ($r = .540$, $p < .01$) and fewer sit-to-stand transitions were associated with poorer Stroop performance ($r = .512$, $p < .01$).

Conclusion: Although there was no significant difference in cognitive ability after a week of increased ST, trends suggest visuospatial abilities may be sensitive to movement behavior. Because executive and spatial functions support independence in aging, identifying behavioral risk factors is essential. Experimental evidence can clarify the dose and type of sedentary behavior most detrimental to cognition in older adults, but there are challenges with adherence to this protocol.

II-P-A.03

Digitally-supported Geriatric Rehabilitation at Home: Perspectives of Older Adults and Healthcare Professionals on Nutrition and Physical Activity Rehabilitation Interventions

E.N. Klaassen^{1,2,3}, N. van der Spek^{2,3}, S.M. de Droog⁴, A.H. Hengelaar^{5,6}, J.D. Schoufour^{1,2}, M.S. Holstege^{7,8,9}, M. van der Schaaf^{2,10,11}, P.J. Weijs^{1,2,12}, B. Visser^{2,3,13}, D. Bossen²

¹Amsterdam University of Applied Sciences, Department of Nutrition and Dietetics, Faculty of Health, Sport and Physical Activity, Amsterdam, Netherlands, ²Amsterdam University of Applied Sciences, Centre of Expertise Urban Vitality, Faculty of Health, Sport and Physical Activity, Amsterdam, Netherlands, ³Amsterdam Movement Sciences, Ageing and Vitality, Amsterdam, Netherlands, ⁴Amsterdam University of Applied Sciences, Digital Life, Amsterdam, Netherlands, ⁵Leiden University, Department Public Health and Primary Care, Leiden University Medical Centre, Leiden, Netherlands, ⁶Amsterdam University of Applied Sciences, Department of Occupational Therapy, Faculty of Health, Sport and Physical Activity, Amsterdam, Netherlands, ⁷GRZPLUS, Department of Research GRZPLUS; Omring and Zorgcirkel, Hoorn, Netherlands, ⁸Omring, Department of Research Omring, Hoorn, Netherlands, ⁹InHolland University of Applied Sciences, Research group geriatric rehabilitation, Centre of Expertise Prevention in Health and Social Care, Faculty of Health, Sports and Social work, Amsterdam, Netherlands, ¹⁰Amsterdam University of Applied Sciences, Department of Physiotherapy, Faculty of Health, Sport and Physical Activity, Amsterdam, Netherlands, ¹¹Amsterdam UMC location University of Amsterdam, Department of Rehabilitation Medicine, Amsterdam, Netherlands, ¹²Vrije Universiteit Amsterdam, Department of Nutrition and Dietetics, Amsterdam University Medical Centers, Amsterdam Movement Sciences, Amsterdam, Netherlands, ¹³Vrije Universiteit Amsterdam, Department of Human Movement Sciences, Faculty of Behavioural and Movement Sciences, Amsterdam Movement Sciences Research Institute, Amsterdam, Netherlands

Purpose: Healthy lifestyle behaviors, including adequate nutrition and regular physical activity, are essential for recovery following geriatric rehabilitation (GR). However, after discharge and returning home, many older adults struggle to maintain these behaviors leading to physical and functional decline. Blended care – combining face-to-face and digital support – may support self-management and continuity of rehabilitation, yet its implementation in everyday practice remains underexplored. As part of the BITE-IT project, this study explores the experiences and needs of older adults and healthcare professionals (HCPs) to guide the development of a blended care intervention for home-based rehabilitation.

Methods: Semi-structured interviews were conducted with older adults (≥ 60 years, $n=16$) who returned home after recent discharge from inpatient GR. Furthermore, three focus groups were held with HCPs ($n=16$) from primary care and GR settings. Data were thematically analyzed in MAXQDA using a primarily inductive approach.

Results: Older adults described **returning home after GR as challenging**. Many experienced fatigue, reduced energy, and difficulties adapting to daily routines, often leading to dependence on support for ADL-activities. The transition required participants to **take more responsibility for their recovery** demanding more **self-management**.

A. AGEING

Motivation and **social support** played a key role in their confidence and persistence. **Awareness** of the importance of **adequate nutrition and protein intake** in supporting recovery **was limited**, and the expertise of dietitians was insufficiently integrated within post-discharge care. **Digital tools were generally viewed positively** by patients actively engaged in their recovery. **Loss of personal contact with HCPs and practical barriers were expressed as concerns**, highlighting the need for personalized guidance and support.

HCPs explained that **interdisciplinary collaboration is frequently fragmented**, with dietitians often insufficiently involved. They highlighted the potential of a shared electronic health record to improve coordination. **Blended care was considered promising** but most effective when patients' and HCPs' abilities, digital literacy, and preferences were considered. HCPs identified **professional support and integration into existing workflows** as key elements for successful use.

Conclusion: Blended care has the potential to enhance home-based GR by supporting motivation, self-management, interprofessional collaboration, and increase awareness of nutrition and protein intake. Its success depends on personalized, simple, and well-integrated approaches that complement face-to-face care.

II-P-A.04

Sedentary Time and Prevention of Obesity and Weight Gain in Adults: A Systematic Review with Meta-analysis

U. Ekelund¹, M. Adriano Sanchez-Lastra², P.T. Katzmarzyk³, S.A. Prince⁴, J. Tarp¹, on behalf of the OBCT Consortium
¹Norwegian School of Sports Sciences, Oslo, Norway, ²University of Vigo, Pontevedra, Spain, ³Pennington Biomedical Research Center, Louisiana, United States, ⁴Public Health Agency of Canada, Ottawa, Canada

Purpose: Determine the prospective association between sedentary time and prevention of weight gain and obesity among adults through a systematic review and meta-analysis.

Methods: A systematic search was conducted in PubMed, EBSCO CINAHL, and SPORTDiscus from inception until September 29, 2024. Eligible prospective studies included general population ostensibly healthy adults aged 18 – 65 years at baseline, had minimum 2 years follow-up, a sample size of ≥200 participants, and measured any form of sedentary time. The primary outcome was incident obesity and secondary outcomes included weight change, adiposity, and body composition. Incident obesity was combined with studies on incidence of weight gain (variously defined) due to few studies. Eligible studies were identified through a combination of human and computer-assisted screening. Two reviewers independently extracted the data. Estimates from individual studies were synthesised using random-effects meta-analysis where possible. This review is registered with PROSPERO (CRD42024596491).

Results: Forty-three unique publications from 26 cohorts were included. The most frequently reported outcomes were body mass index (n=21 publications, hereof 6 on incident obesity), body weight (n=14), and waist circumference (n=9). TV viewing and total sitting/sedentary time were the most frequent exposures, reported in 20 and 11 publications, respectively. Four cohorts, including 9935 cases, 81,662 participants, and an average follow-up of 6.3 years, were included in a meta-analysis of leisure time sitting and incident obesity weight gain. For each additional hour of leisure sitting above baseline (1 hour and 15 minutes/day), the risk of obesity increased by 3% (RR: 1.03, 95%CI: 1.01, 1.05) with some evidence of a non-linear dose-response pattern (p=0.04). Based on a meta-analysis of 5 studies with an average of 7.7 years of follow-up, a 1-hour increase in daily sedentary time from baseline to follow-up (i.e., modelling change in sedentary time) was associated with a 0.01 (95%CI, 0.00, 0.02) kg higher gain in body weight/year. Heterogeneity in exposure and outcome definitions challenge pooled analyses which leaves uncertainty in reported effect-sizes.

Conclusion: Higher sedentary time, and increasing sedentary time over time, is associated with a slight increased risk of obesity and weight gain. The effect of sedentary time on weight gain, if causal, appears small compared to other health outcomes.

II-P-A.05

Long-term Physical Activity and Risk of Obesity in Australian Women Using Target Trial Emulation: An OBCT Study

J. Tarp¹, M.A. Sanchez-Lastra², K.E. Dalene³, M. Luo⁴, B. Nguyen⁴, G. Iven Mielke⁵, U. Ekelund¹, D. Ding⁴, P. Clare⁴, on behalf of the OBCT Consortium

¹Norwegian School of Sports Sciences, Oslo, Norway, ²University of Vigo, Pontevedra, Spain, ³Norwegian Institute of Public Health, Oslo, Norway, ⁴The University of Sydney, Sydney, Australia, ⁵The University of Queensland, Brisbane, Australia

A. AGEING

Purpose: Determine the causal effect of long-term adherence to the WHO-recommended level of physical activity throughout middle-age on the incidence of obesity using target trial emulation.

Methods: This study emulated a target trial using observational data from the Australian Longitudinal Study on Women's Health collected at triennial surveys between 1996 and 2022. The target trial would assess the effect of randomizing women to either meeting or not meeting the WHO-recommended level of physical activity over an 18-year period on the 21-year incidence of obesity. Targeted maximum likelihood estimation controlling for time-constant and time-varying confounders was used to emulate the target trial, assuming conditional exchangeability, positivity, consistency, and no interference. Participants were Australian women with a body mass index between 18.5 and $< 30 \text{ kg/m}^2$ and a physical function score above the 5th percentile. The exposure was 18-years of consistent adherence to the physical activity recommendation, defined as engaging in ≥ 150 minutes of moderate-to-vigorous physical activity per week, versus consistent non-adherence to the recommendation. Physical activity was self-reported. The outcome was the 21-year incidence of obesity (self-reported body mass index $\geq 30 \text{ kg/m}^2$).

Results: 4,779 women aged 47 to 52 years at study entry were included. The cumulative incidence of obesity was 9.9% (99.5% CI: 8.6%, 11.1%) in the scenario with 18-year adherence to the recommendation and 15.1% (99.5% CI: 12.8%, 17.4%) with consistent non-adherence (risk ratio: 1.5 [99.5% CI: 1.2, 1.9], risk difference: 5.3 %-point [99.5% CI: 2.3%, 8.3%]). Meeting the recommendation in one to seven surveys reduced obesity risk in a linear dose-response manner. Sensitivity analyses suggested robustness to unmeasured confounding.

Conclusion: Long-term adherence to the recommended ≥ 150 minutes of moderate-to-vigorous physical activity per week reduced the risk of obesity in middle-aged women. The risk of obesity decreased linearly as adherence increased. These findings underscore the importance of sustained physical activity promotion for long-term obesity prevention and public health strategies.

II-P-A.06

A Family History of Depression and Physical Activity in Older Adults: Associations with Current Depressive Symptoms in the German National Cohort (NAKO)

F. Herbolzheimer¹, J. Konzok², H. Baurecht³, K. Steindorf¹

¹German Cancer Research Center, Division of Physical Activity, Cancer Prevention and Survivorship, Heidelberg, Germany,

²University of Regensburg, Institute of Psychology, Regensburg, Germany, ³University of Regensburg, Department of Epidemiology and Preventive Medicine, Regensburg, Germany

Purpose: Depressive symptoms are particularly prevalent among individuals with a family history of depression. The present study aimed to investigate the association between accelerometer-assessed physical activity and depressive symptoms in older adults, with a specific focus on the role of parental history of depression.

Methods: Analyses were conducted on a subsample of 16,161 older adults (aged 60–74 years; mean age = 64.8 years; 49.3% female) from the German National Cohort (NAKO) who provided valid accelerometer data and complete questionnaire information. The outcome variable, current depressive symptoms, was assessed using the Patient Health Questionnaire-9 (PHQ-9). Parental history of depression was obtained through self-report, and physical activity was objectively measured with an ActiGraph accelerometer, processed using the Mean Amplitude Deviation algorithm. Generalized linear models were used to examine main and moderation effects, adjusting for sex, body mass index, social network size, education, and employment status.

Results:

Participants with a parental history of depression (11.4%) reported significantly higher depressive symptom scores compared to those without such a history ($M_{\text{family history}} = 4.19$; 95% CI [4.01, 4.36] vs. $M_{\text{No family history}} = 3.14$; 95% CI [3.09, 3.19]; $p < 0.001$). In multivariable linear models, higher levels of physical activity were associated with lower depressive symptom scores ($\beta = -0.042$, $p < 0.001$). This corresponds to a reduction of 0.24 points in symptom score for every 10-unit increase of physical activity. Importantly, physically active older adults with a parental history of depression exhibited significantly fewer depressive symptoms than their less active counterparts ($\beta = -.058$, $p = 0.024$), indicating a potential moderating effect of physical activity.

Conclusion:

These findings suggest that higher levels of physical activity are associated with reduced depressive symptoms in older adults at elevated familial risk. Promoting physical activity may therefore serve as a promising preventive strategy for mitigating depressive symptoms in this vulnerable population.

II-P-A.07

The Optimal Combination of Physical and Cognitive Activity in Older Adults to Promote Cognitive Functioning: Preliminary Results of the CONSCIOUS Study

L. Leenknecht^{1,2}, J. van Uffelen¹, G. Cardon², J. Latomme², S. Chastin^{3,2}

¹KU Leuven, Department of Movement Sciences, Leuven, Belgium, ²University of Ghent, Department of Movement and Sports Sciences, Ghent, Belgium, ³Glasgow Caledonian University, Department of Allied Health Professions, Glasgow, United Kingdom

Purpose: Although life expectancy has increased due to medical advances, there has not been a corresponding rise in healthy life expectancy without cognitive decline. Evidence supports the effectiveness of combining physical and cognitive activity (PA + CA) to promote healthy cognitive ageing, yet the optimal balance between these components remains unclear. This insight is crucial for optimizing interventions targeting prevention of cognitive decline, particularly considering today's ageing society. Therefore, this study aims to identify which combination of PA intensity and CA difficulty yields the greatest cognitive benefits in healthy, community-dwelling older adults.

Methods: Sixty-eight older adults aged 65+ with varying levels of cardiorespiratory fitness will be invited to participate in a familiarization session to determine two PA intensity levels (light and moderate) and two CA difficulty levels (easy and challenging). PA intensity will be defined by heart-rate zones calculated based on the percentage of the heart-rate reserve. CA difficulty will be determined based on subjective ratings and objective performance of participants. Following this, participants will be invited to complete all four PA + CA combinations (light/moderate PA x easy/challenging CA) in a controlled laboratory setting where they walk on a treadmill at a given intensity while performing cognitive tasks at a certain difficulty. Immediately before and after each combination inhibition, cognitive flexibility, and complex attention will be assessed.

Results: Preliminary findings presented at the conference will compare the acute effects of the four combinations on all cognitive outcomes. Additionally, feasibility and enjoyment ratings obtained after each combination will be used to evaluate task acceptability and participant engagement.

Conclusion: This study is the first to experimentally manipulate both PA intensity and CA difficulty in a controlled setting to identify the optimal PA + CA "dose" for immediate cognitive enhancement. The findings will contribute to a clearer understanding of how simultaneous PA and CA can be tailored to maximize short-term cognitive benefits in older adults, thereby advancing the scientific basis for future applied research on brain health promotion.

II-P-A.08

Selective Effects of Resistance Exercise on Cognitive Function in Older Adults

I. Martin-Fuentes¹, B. Fernandez-Gamez¹, P. Solis-Urra^{2,1,3}, A. Coca-Pulido¹, C. Molina-Hidalgo², M. Olvera-Rojas¹, E.A. Bakker^{4,1}, D. Bellón¹, A. Sclafani¹, J. Mora-Gonzalez¹, J. ¹University of Granada, Sport and Health University Research Institute, Department of Physical Education and Sports, Granada, Spain, ²AdventHealth Research Institute, Neuroscience, Orlando, United States, ³Universidad Andres Bello, Faculty of Education and Social Sciences, Viña del Mar, Chile, ⁴Radboud University Medical Center, Department of Primary and Community Care, Nijmegen, Netherlands, ⁵Hospital Universitario Virgen de las Nieves, Servicio de Medicina Nuclear, Granada, Spain, ⁶Instituto de Investigación Biosanitaria ibs., Granada, Spain, ⁷University of British Columbia, Department of Physical Therapy, Vancouver, Canada, ⁸Vancouver Coastal Health Research Institute, Centre for Aging SMART at Vancouver Coastal Health, Vancouver, Canada, ⁹Vancouver Coastal Health Research Institute, Djavad Mowafaghian Centre for Brain Health, Vancouver, Canada, ¹⁰Instituto de Salud Carlos III, Centro de Investigación Biomédica en Red Fisiopatología de la Obesidad y Nutrición (CIBERObn), Madrid, Spain, ¹¹University of Jyväskylä, Faculty of Sport and Health Sciences, Jyväskylä, Finland

Purpose: Physical exercise is a promising non-pharmaceutical strategy to delay cognitive decline in aging. However, the limited understanding of the mechanisms by which exercise impacts cognition and the poor description of exercise programs in late adulthood hinder its implementation as a therapeutic or preventive approach for Alzheimer's Disease (AD) cognitive decline, especially resistance training. Few studies with well-characterized samples and comprehensive cognitive assessments have attempted to understand the moderator role of key demographics/clinical variables on the effect of resistance exercise on cognition, as well as to identify the brain mechanisms underlying these cognitive benefits. This study aims to uncover the effects of a 24-week resistance exercise intervention on cognitive performance,

A. AGEING

considering key moderators of the effect.

Methods: The AGUEDA trial is a single-site, two-arm, single-blinded, randomized controlled trial (RCT) involving 90 cognitively normal older adults from Spain, (65-80 years). We will share promising findings on the impact of exercise on cognitive subdomains such as attentional/inhibitory control, episodic memory, processing speed, visuospatial memory and working memory, with a focus on optimizing the effect based on moderation analysis. Demographics and key clinical characteristics such as sex, age, education level, number of comorbidities, apolipoprotein E carrier, Amyloid burden, baseline cognitive performance of each cognitive outcome and subjective cognitive decline are explored as potential moderators of the exercise's impact on cognition. In addition, we discuss the brain pathways with a particular focus on hippocampus- linking exercise to cognitive resilience in aging.

Results: Resistance exercise improve the attention/inhibitory control, but no other cognitive domains benefits were identified compared to control. Remarkably, we were able to identify greater benefits for older individuals with lower education levels, and those with high subject cognitive decline. Hippocampus did not appear to mediate the effects of exercise on cognition. High adherence was observed, with and no serious adverse events occurred.

Conclusion: This research demonstrates the selective potential of resistance exercise as a powerful tool in the new era of precision interventions targeting specific AD-related cognitive decline. It also provides valuable insights into optimizing benefits based on patient characteristics, necessitating a thorough exploration of the underlying mechanisms linking exercise to cognition during aging.

II-P-A.09

Individual and Combined Associations of Physical Activity and Cognitive Function with All-cause Mortality in Older Ages: A Prospective Analysis of the German National Cohort (NAKO)

D. Georges^{1,2,3}, E. Rakuša^{2,4}, G. Doblhammer^{2,4}

¹German Center for Child and Adolescent Health (DZKJ), partner site Greifswald/Rostock, Rostock, Germany, ²University of Rostock, Faculty of Economic and Social Sciences, Rostock, Germany, ³Rostock University Medical Center, Rostock, Germany, ⁴German Center for Neurodegenerative Diseases, Bonn, Germany

Purpose: Low physical activity (PA) and poor cognitive function are associated with higher mortality risks. However, little is known about their interaction, including whether PA may moderate cognition-related mortality risks. This study examines the combined associations of PA and cognition with all-cause mortality, with attention to sex differences.

Methods: Using data from the German National Cohort (NAKO) and its mortality follow-up, we analyzed mortality risk based on:

- baseline low vs. sufficient PA (assessed via the global physical activity questionnaire using a threshold of < vs. ≥ 600 MET-minutes/week),
- baseline low vs. medium vs. high semantic memory (SM) and executive function/processing speed (EF/PS), assessed through factor analyses of a neurocognitive test battery, and
- their interaction on mortality in individuals aged 65+ up to 10 years of follow-up (N=28,892).

Cox models were estimated both in the total sample and stratified by sex, adjusting for relevant confounders and reporting both distinct and combined associations.

Results: During follow-up, 1,605 individuals (5.6%) died: 1,097 men (7.5%) and 508 women (3.6%). Compared to individuals with low cognitive function, those with high SM (Hazard Ratio (HR)=0.83 [95%CI: 0.67–1.02]), as well as high EF/PS (HR=0.66 [0.53–0.83]) and medium EF/PS (HR=0.68 [0.60–0.78]) had lower mortality risks. PA was associated with a 29% decreased mortality risk (HR=0.71 [0.62–0.82]) compared to low PA. PA moderated the elevated risk from low cognition, especially with regard to EF/PS. The associations did not differ between men and women.

Conclusion: Maintaining cognitive function and PA in older age is relevant for reducing mortality risk in both men and women. PA may offset risks linked to low cognition in both sexes, though mechanisms require further study.

II-P-A.10

Pilot Randomized Control Trial of Two Novel Food Prescriptions Interventions for Older Adults Experiencing Food Insecurity

L. Leone¹, A. Lally¹, R. Paluch², J. Stoll³, J. Tirabassi³

¹University at Buffalo, Community Health and Health Behavior, Buffalo, NY, United States, ²University at Buffalo, Pediatrics, Buffalo, NY, United States, ³University at Buffalo, Family Medicine, Buffalo, NY, United States

Purpose: Food prescriptions are an increasingly popular approach for addressing food security and improving health outcomes (i.e., Food is Medicine), but they are underused. For this pilot, we worked with a Community Advisory Board of older adults to design two novel food prescription programs that could overcome barriers to food prescription usage.

Methods: Participants aged 65+ experiencing food insecurity (N=67) were recruited from primary care clinics and randomized to one of three arms for 12 weeks: 1.) home-delivered produce prescription intervention (n=22); 2.) home delivered meal kit intervention (all ingredients and recipes to make three meals) (n=23) and 3.) standard for care control (SOCC) produce prescription redeemed at a mobile market at their clinic or other convenient location (n=22). Intervention arm participants received a default food delivery but could customize or skip their delivery if they chose. All arms included the same quantity of fruits and vegetables (F&Vs), cooking equipment, and educational materials. Phone surveys at baseline and 12 weeks were used to collect data on F&V intake, nutrition/food security, and health status.

Results: Nutrition security improved in both intervention arms compared to SOCC mobile market arm ($p<0.005$). Food security also improved significantly ($p=0.006$) in the meal kit arm (-1.83 SD 2.35) compared to the SOCC (0.41 SD 2.21). F&V consumption increased by 0.7 times/day in both intervention arms compared to 0.2 times/day in the SOCC, but this difference was not statistically significant. Both intervention arms reported eating more leafy greens and salsa than SOCC ($p<0.05$). Self-reported health ratings were also higher in the intervention groups vs. the SOCC ($p<0.05$).

Conclusion: Delivered food prescriptions helped older adults improve nutrition security, likely by eliminating barriers to accessing fresh F&V. While we hypothesized that the meal kits would help participants prepare and eat more F&Vs, we did not see differences in F&V intake vs. the produce-only prescriptions. Improvements in food security among those who received meal kits may be due to the higher overall quantity of food received.

II-P-A.12

Associations between Field-based Physical Function Tests and Life's Essential 8 in Individuals with Coronary Artery Disease: A Cross-sectional Analysis from the Heart-Brain Trial

E.J. Barranco-Moreno¹, S. Vidal-Almela¹, L. Sánchez-Aranda¹, R.M. Alonso-Cuenca², R. García-Orta^{3,4}, E. Moreno-Escobar^{2,4}, A. Sclafani¹, J. Sanchez-Martinez¹, M. Olvera-Rojas¹, A. Toval¹, F.B. Ortega^{1,5,6}

¹University of Granada, Department of Physical and Sports Education, Sport and Health University Research Institute (iMUDS), Faculty of Sport Sciences, Granada, Spain, ²San Cecilio Clinical University Hospital, Cardiology Service, Granada, Spain, ³Virgen de Las Nieves University Hospital, Cardiology Service, Granada, Spain, ⁴Instituto de Investigación Biosanitaria, ibs.Granada, Granada, Spain, ⁵Instituto de Salud Carlos III, CIBER de Fisiopatología de la Obesidad y Nutrición (CIBEROBN), Madrid, Spain, ⁶University of Jyväskylä, Faculty of Sport and Health Sciences, Jyväskylä, Finland

Purpose: Many coronary artery disease (CAD) deaths may be prevented by addressing modifiable cardiovascular disease risk factors. In this context, the American Heart Association created the Life's Essential 8 (LE8) framework to quantify cardiovascular health (CVH) based on eight health behaviors and factors. Further, physical function is also clinically relevant, although it is unclear which field-based physical function tests most closely align with CVH as defined by LE8. We aimed to identify which field-based physical function tests are most strongly associated with the LE8 score in individuals with CAD.

Methods: This cross-sectional analysis from the Heart-Brain trial included individuals with stable CAD. Participants completed field-based physical function tests including the 6-minute walk test (6MWT), 30-second sit-to-stand (30s-STs), timed up and go, 2-minute step test, handgrip strength, and arm-curl test. LE8 components were assessed to derive a 0-100 score: physical activity and sleep (accelerometry), diet (MEDAS questionnaire), nicotine exposure (self-reported), glucose and lipids (fasting blood samples), body mass index (anthropometric measurements) and

A. AGEING

blood pressure (sphygmomanometer). Linear regression models were adjusted for age, sex, and education.

Results: 102 individuals were evaluated (21 females, 62.3±6.6 years). Descriptive characteristics of the study sample were (mean±SD): LE8 score, 66.6±8.6 pts; 6MWT, 566±71.9 m; 30s-STs, 16.7±4.3 repetitions; timed up and go, 4.8±0.7 s; 2-minute step test, 89.7±21.9 repetitions; handgrip strength, 37.1±8.4 kg; and arm-curl test, 19.8±4.1 repetitions. The 6MWT ($\beta_{std}=0.47$; $p<0.001$) and 2-minute step test ($\beta_{std}=0.23$; $p=0.02$) showed significant positive associations with the LE8 score. No significant associations were observed for 30s-STs ($\beta_{std}=0.16$; $p=0.14$), arm-curl score ($\beta_{std}=0.04$; $p=0.72$), handgrip strength ($\beta_{std}=-0.10$; $p=0.51$), or timed up and go ($\beta_{std}=-0.12$; $p=0.26$).

Conclusion: The 6MWT showed the strongest association with the LE8 score, while the 2-minute step test showed a weaker yet significant association. These findings support the 6MWT as a low-cost, feasible marker of CVH for routine clinical practice in adults with stable CAD.

II-P-A.13

Effects of A 24-week Resistance Exercise Intervention on White Matter Hyperintensity: Findings from the AGUEDA Trial

J. Fernández-Ortega¹, I. Martín-Fuentes¹, P. Solís-Urra^{1,2,3}, J. Sanchez-Martinez¹, B. Fernandez-Gamez¹, K.I. Erickson^{2,4}, F.B. Ortega^{1,5}, I. Esteban-Cornejo^{1,5,6}

¹Department of Physical Education and Sports, Faculty of Sport Sciences, Sport and Health University Research Institute (iMUDS), University of Granada, Granada, Spain, ²AdventHealth Research Institute, Neuroscience Institute, Orlando, FL, United States, ³Faculty of Education and Social Sciences, Andrés Bello University, Viña del Marchile, Chile, ⁴Department of Psychology, University of Pittsburgh, Pittsburgh, United States, ⁵Centro de Investigación Biomédica en Red Fisiopatología de la Obesidad y Nutrición (CIBERObn), Instituto de Salud Carlos III, Madrid, Spain, ⁶Instituto de Investigación Biosanitaria ibs. GRANADA, Granada, Spain

Purpose: We examined whether a 24-week resistance exercise (RE) intervention modifies global White Matter Hyperintensity (WMH) burden and whether change in global WMH associates with change in attentional control. This study is innovative because it links longitudinal WMH progression to cognitive change and tests whether exercise modifies this connection.

Methods: Brain MRI sequences were acquired on a 3T Siemens Magnetom TIM Trio scanner (T1-weighted and 3D FLAIR sequences). The UBO-Detector pipeline was used to quantify global WMH volume. Attentional control z-score was derived from cognitive tests. As part of the AGUEDA trial, participants were randomly allocated to the Resistance Exercise group or to a usual-activities control group. The Resistance Exercise group performed 180 minutes/week of supervised training, while the control group maintained usual activities.. An intention-to-treat analysis was applied on WMH using constrained linear mixed models and post-intervention between-group contrasts. Linear regression models examined whether change scores in WMH were correlated with changes in attentional control.

Results: Analyses included 80 participants (mean age 71.4 ± 3.9 years, 54.4% women). No significant between-group differences were observed in global WMH (SMD= 0.08, 95% CI -0.13 to 0.28; $p = 0.457$). The association between change in WMH and change in attentional control was not significant in the whole sample ($\beta = 0.20$, 95% CI -0.17 to 0.56; $p = 0.288$), the control group ($\beta = 0.05$, 95% CI -0.51 to 0.60; $p = 0.865$) or the exercise group ($\beta = 0.31$, 95% CI -0.15 to 0.77; $p = 0.186$).

Conclusion: RE intervention did not change global WMH burden over 24 weeks. In parallel, changes in WMH were not linked to changes in attentional control. It is possible that longer intervention periods are required to detect structural changes in WMH, particularly in cognitively healthy older adults with relatively low baseline WMH burden.

II-P-A.14

Mapping of National Surveys on Physical Activity, Sedentary Behavior among Older Adults in South America

J. Caldas dos Santos¹, J.C. do Nascimento Melo², R.H. de Oliveira Araújo³, L. Santos Castro¹, M. Bethania Marchetti¹, I. Fernanda de Freitas Cunha¹, P. Yukari Sewo Sampaio⁴, J. Brazo Sayavera⁵, R. Aurélio Carvalho Sampaio⁶, D. Rodrigues Pereira da Silva⁶

¹Federal University of Sergipe, Postgraduate Program in Health Sciences, Sergipe, Brazil, ²State University of Londrina, Postgraduate Program in Health Sciences, Paraná, Brazil, ³Klaipeda University, Health Research and Innovation Science Centre, Faculty of Health Sciences, Klaipeda University, Klaipeda, Lithuania, ⁴Federal University of Sergipe, Department

A. AGEING

of Occupational Therapy, Lagarto, Brazil, ⁵Pablo de Olavide University, Doctoral School of Physical Activity and Sport Sciences, Seville, Spain, ⁶Federal University of Sergipe, Department of Physical Education, Sergipe, Brazil

Purpose: Surveillance of physical activity (PA) and sedentary behavior (SB) is essential to monitor the health behaviors of the older population and inform public policies. In South America, despite the existence of national surveys, how these data are structured and whether they are comparable remains unclear. This study aimed to map national surveys conducted in South America that included information on PA and SB among individuals 60 years of age or older.

Methods: A mapping study was conducted across the 12 South American countries through searches of official websites of Ministries of Health and National Institutes of Statistics, as well as international repositories, including the World Health Organization, Pan American Health Organization, and the STEPwise Approach to Noncommunicable Disease RiskFactor Surveillance. For this study, only surveys with nationally representative samples with information on PA and/or SB among individuals aged ≥ 60 years were included, considering their different editions and methodologies.

Results: A total of 53 national surveys were identified. Twenty surveys of older adults from eight countries (Argentina, Brazil, Chile, Colombia, Ecuador, Paraguay, Peru, and Uruguay) were included. PA was assessed in all surveys, whereas SB was not all surveys evaluated. All surveys used only self-report methods. Heterogeneity was observed in PA instruments: 60% ($n = 12$) used country-specific questionnaires, whereas 40% adopted international protocols (International Physical Activity Questionnaire [IPAQ] or Global Physical Activity Questionnaire [GPAQ]). Only 30% ($n = 6$) assessed multiple domains of PA. SB was predominantly measured through total sitting time (57%), while 43% focused on screen time.

Conclusion:

National surveys in South America show significant heterogeneity in assessment methods, with no objective, device-based measurements. Improving the standardization of protocols across life domains is essential to provide high-quality evidence to address sedentary lifestyles in the region's aging population.

II-P-A.15

Cardiorespiratory Fitness Outcomes in Older African Americans: The Reducing African Americans' Alzheimer's Disease Risk Through Exercise (RAATE) Study

R. Newton¹, R. Beyl¹, K. Drews¹, C. Hebert¹, N. Johannsen², O. Carmichael¹

¹Pennington Biomedical, Baton Rouge, United States, ²Louisiana State University, Baton Rouge, United States

Purpose: Older African Americans engage in low levels of physical activity, which increases risk for dementia. Few physical activity interventions have been conducted in older African Americans. The purpose of this study is to determine engagement in, and the effect of, a physical activity intervention targeting older African Americans.

Methods: There were 129 sedentary, cognitively healthy, older African Americans randomized to a 52-week physical activity (PA) or successful aging (SA) group. PA participants met twice weekly for supervised exercise and SA participants met weekly for education and light exercise. Participants completed a treadmill cardiorespiratory fitness test and changes in cardiorespiratory fitness (estimated maximal and submaximal outcomes) between baseline and week 52 were compared between PA and SA groups using repeated measures ANOVA models, in intention to treat (ITT) and completers analyses.

Results: A total of 126 individuals (mean age 67.8 ± 5.3 years; 77% female; 65% college degree or more; 44% married) were randomized (61/65 PA/SA) and included in the ITT analysis. Attendance in PA and SA group sessions was 86.9% and 86.3%, respectively. The PA group had a marginally significant increase in maximal METS ($p = 0.071$) compared to the SA group, driven by greater PA group improvements in treadmill incline ($p = 0.001$). Both groups improved submaximal METS (80%APHRmax; p values < 0.033). There were no between group differences in absolute or relative peak VO_2 (p values > 0.227), submaximal VO_2 ($p = 0.130$), estimated maximal VO_2 ($p = 0.231$), estimated submaximal VO_2 ($p = 0.480$), or maximum heart rate ($p = 0.563$). The results were similar in the completers analysis ($n = 113$).

Conclusion: Participants in the physical activity group showed improvements work rate and both groups improved submaximal fitness. Most outcomes were in the expected direction (improvements in the PA group and no change in the SA group) for non-significant findings. The RAATE study is one of few to show cardiorespiratory fitness changes in older African Americans after one year. It will be important to determine if physical activity changes are associated with a reduction in dementia risk factors.

B. MOTIVATION AND BEHAVIOR CHANGE

I-P-B.01

Exploring Concepts and Existing Research on Protein Literacy: A Scoping Review

S. Boudrey¹, H. Begum², K. Santos², A. Hawley¹, E. Børshheim³, E.C. Diaz Fuentes³, J.C. Robinson¹, J.I. Baum¹

¹University of Arkansas Division of Agriculture, Fayetteville, United States, ²University of Arkansas, Fayetteville, United States, ³University of Arkansas for Medical Sciences, Little Rock, United States

Purpose: Public and scientific interest in dietary protein continues to grow, yet many individuals remain unaware of their daily protein needs. Given the increase in attention to protein intake in both public health messaging and consumer trends, there is a developing need to examine the concept of protein literacy and how it influences dietary behaviors. The purpose of this scoping review is to synthesize published research on protein literacy including assessment tools, educational sessions, and developed frameworks.

Methods: Our scoping review followed the Arksey and O'Malley framework, complied with the Joanna Briggs Institute (JBI) guidance for data extraction, and was registered in the Open Science Framework. We searched CINAHL, PubMed, Web of Science, ProQuest, CDC Stacks, and CENTRAL up until May 2025. Studies were included if they presented a protein literacy model, framework, assessment tool, intervention, or program.

Results: Nineteen studies met the inclusion criteria for this scoping review. Sixteen included an assessment tool measuring dietary protein knowledge, perceived attitudes, and nutritional importance. The tools most often assessed factual knowledge about protein intake and sources, while few addressed behavioral application or communication skills related to protein sources. Few assessment tools were developed using validated literacy framework (n=5) and none based on a protein literacy framework. Most instruments did not assess validity while approximately half reported reliability (n=10). Three studies gathered qualitative data through semi structured interviews or focus groups to explore perceptions of protein adequacy and understanding dietary guidance. Most studies focused on adult populations (n=14).

Conclusion: Findings reveal the inconsistency in defining and measuring protein literacy. Current approaches tend to isolate knowledge or attitudes without considering interactive or critical dimensions such as application in real-world settings. A comprehensive, theory-driven framework is needed to guide the development of validated assessment tools and educational programs that capture the multifaceted nature of protein literacy.

I-P-B.02

Developing a Conceptual Framework for Dietary Protein Literacy: A Thematic Analysis of Expert Interviews

S. Boudrey¹, R. Smith², A. Hawley¹, E. Børshheim³, E.C. Diaz Fuentes³, J.C. Robinson¹, J. Baum¹

¹University of Arkansas Division of Agriculture, Fayetteville, United States, ²University of Arkansas, Fayetteville, United States, ³University of Arkansas for Medical Sciences, Little Rock, United States

Purpose: Protein plays an important role in health and disease prevention, yet public understanding of appropriate intake, quality, and sources remains limited. This gap shows the need for a comprehensive protein literacy framework that defines how individuals demonstrate the ability to assess, interpret, and apply information about dietary protein. Developing such a framework is necessary to guide future education efforts, assessment development, and behavioral research in this area. The primary aim of the study is to gather feedback from experts on the development of a conceptual framework for protein literacy, grounded in Nutbeam's model of health literacy, which includes functional, interactive, and critical domains.

Methods: Semi-structured interviews are being conducted via zoom with experts, health professionals, and other stakeholders to gain insight into key concepts and perspectives surrounding dietary protein literacy. Interviews are audio recorded and transcribed verbatim. Braune and Clark's reflexive thematic analysis approach is being applied to systematically code the data and identify emerging patterns and key themes from the interviews. A primarily deductive analytical process is used to organize the themes according to the domains of functional, interactive, and critical literacy while also allowing for inductive insights to capture unique aspects of protein literacy that may exist beyond frameworks.

Results: Preliminary findings indicate consensus on various key elements to include in the emerging framework. The functional domain centers on foundational knowledge such as understanding protein sources, quality, and recommended intakes. Interactive protein literacy involves the ability to communicate protein related information

B. MOTIVATION AND BEHAVIOR CHANGE

and apply knowledge to make informed protein related decisions. The critical domain encompasses the ability to evaluate credibility of protein related information and make decisions aligned with health goals. Participants also emphasized the need for the framework to include cultural and contextual factors.

Conclusion: Analysis will inform the development of a comprehensive and theory-driven protein literacy framework that integrates the functional, interactive, and critical domains. This framework will provide a foundation for future assessment tool development, educational interventions, and research aimed at improving protein related knowledge and behaviors.

I-P-B.03

The Association of Physical Activity and Strength on Bone Health: Is Menopausal Age Modifying this Association? Evidence from NHANES 2013–2014

O. Ayoola¹, H. Sahni¹, M. York¹, J. Bravo¹, V. Jaisree Mohandas¹, O. Amaral de Andrade Leao¹

¹University of Illinois, Urbana-Champaign, Health and Kinesiology, Urbana, United States

Purpose: Osteoporosis disproportionately affects women as they transition through menopause, when hormonal changes accelerate bone loss. Physical activity (PA) and muscular strength are protective factors for bone health; however, the extent to which menopausal age modifies these associations remains unclear in nationally representative data. Our study examines the association between physical activity and grip strength with bone health, and to assess whether menopausal age modifies these relationships among adult women.

Methods: Data were drawn from the 2013–2014 National Health and Nutrition Examination Survey (NHANES) for women (n = 5,172) aged ≥ 20 years with complete information on osteoporosis status, grip strength, and PA. A survey-weighted logistic regression model estimated the odds of osteoporosis as a function of total minutes of PA, grip strength, and age group (“<40” & “≥40”), including interaction terms between menopausal group and both PA and grip strength. The model accounted for strata, clusters, and examination weights. It was also adjusted for race, education, and income, and age group was included as an interaction term. Odds ratios (ORs) and 95% confidence intervals (CIs) were calculated.

Results: Higher grip strength was associated with lower odds of osteoporosis (OR = 0.94, 95% CI: 0.92–0.97, *p* = 0.006) suggesting that each one-unit increase in grip strength reduced the likelihood of osteoporosis by about 6%. Total minutes of PA showed an inverse but non-significant association (OR = 0.99, 95% CI: 0.98–1.00, *p* = 0.11). No significant interactions were observed between age group and either PA or grip strength (*p* = 0.12 or 0.31) respectively.

Conclusion: Using nationally weighted data, higher muscular strength seemed to be independently protective against osteoporosis, whereas total PA volume and menopausal age did not significantly influence this relationship. These findings underscore the importance of raising awareness about the benefits of strength training, in conjunction with recommended exercise guidelines, and incorporating strength training into the exercise routines of women across all age groups.

Motivations and Experiences of Adults Using GLP-1 or Dual GLP-1/GIP Agonists for Obesity: Preliminary Findings from a Qualitative Study

I. D'Aout^{1,2,3}, M. Turcotte³, È.-F. Côté^{3,4}, S. Iceta^{5,6}, A.S. Alberga^{7,8}, C. Bégin^{3,4}, S. Desroches^{3,9}, J.-P. Drouin-Chartier^{3,10}, F. Lajeunesse-Trempe^{6,10}, T. Ben-Porat¹¹, M. Côté^{3,12}

¹Université Sherbrooke, Département de Psychologie, Sherbrooke, Canada, ²CISSS de Lanaudière, Département de Chirurgie Bariatrique, Joliette, Canada, ³Université Laval, Centre Nutrition, Santé et Société (NUTRISS), Institut sur la Nutrition et les Aliments Fonctionnels (INAF), Québec, Canada, ⁴Université Laval, École de Psychologie, Québec, Canada, ⁵Université Laval, Département de Psychiatrie et de Neurosciences, Québec, Canada, ⁶Centre de Recherche de l'IIUCPQ, Québec, Canada, ⁷Concordia University, Department of Health, Kinesiology, and Applied Physiology, Montreal, Canada, ⁸Institut de Recherche du Centre Universitaire de Santé McGill, Montréal, Canada, ⁹Université Laval, École de Nutrition, Québec, Canada, ¹⁰Université Laval, Faculté de Pharmacie, Québec, Canada, ¹¹University of Haifa, School of Public Health, Faculty of Social Welfare and Health Sciences, Haifa, Israel, ¹²Université Laval, Faculté des Sciences de l'Éducation, Québec, Canada

B. MOTIVATION AND BEHAVIOR CHANGE

Purpose: GLP-1 receptor agonists (GLP-1As) and dual GLP-1/GIP agonists (GLP-1/GIP-As) are transforming obesity management, yet very few studies have explored adults' experiences using or discontinuing these medications. This study explores adults' experiences using injectable GLP-1As or dual GLP-1/GIP-As for obesity management, focusing on motivational factors underlying treatment initiation and continuation, as well as facilitators and barriers influencing adherence or discontinuation.

Methods: Guided by Self-Determination Theory, this qualitative study used a comprehensive paradigm to explore participants' experiences. A purposeful sample of adults from the province of Québec (Canada) currently using ($n = 13$) or having discontinued ($n = 8$) injectable GLP-1As or GLP-1/GIP-As was recruited through a research volunteer mailing list from an obesity medicine clinic and the general population. Eligible participants completed sociodemographic and brief medical history questionnaires. Individual semi-structured interviews were conducted by the first author via Microsoft Teams and video-recorded. Transcripts were revised for accuracy and analyzed using NVivo 15. Thematic analysis combined inductive and deductive coding and was refined through iterative discussions with co-researchers during three analytic meetings while data was being collected.

Results: Preliminary findings suggest that motivations to initiate GLP-1As and GLP-1/GIP-As treatments were mostly linked to health concerns (e.g., preventing or improving obesity-related co-existing conditions), body image concerns, and repeated challenges with previous weight-management attempts. Barriers to medication initiation were mainly related to cost and potential side effects (e.g., nausea, diarrhea). Participants described perceived benefits such as appetite and satiety regulation, weight loss, enhanced body satisfaction, and greater physical capacity to engage in meaningful activities (e.g., sports). Perceived downsides included financial burden, side effects, and social discomfort (e.g., during shared meals in social settings due to loss of appetite). Participants identified eating habits and physical activity as the behaviors they were most motivated to improve or maintain in the future, with or without medication.

Conclusion: This is among the first qualitative studies to examine adults' motivations, facilitators, and barriers related to the use of GLP-1As and GLP-1/GIP-As medications to support obesity management. These findings highlight the need to consider motivational factors and patients' experiences when integrating pharmacological treatments in obesity care.

I-P-B.05

Moving beyond Appearance: Understanding the Relationship between Physical Activity, Embodiment and Positive Body Image in Men

C. Heath¹, S. Galway¹, K. Gammage²

¹Brock University, Applied Health Sciences, St. Catharines, Canada, ²Brock University, Kinesiology, St. Catharines, Canada

Purpose: The purpose of this study was to investigate whether physical activity predicts positive body image in men, and if this relationship is mediated by increases in embodiment and decreases in self-objectification, consistent with the Embodiment Model of Positive Body Image (Menzel & Levine, 2011).

Methods: A cross-sectional study was conducted with one hundred and forty-two men (18-85 years of age) living in North America. They completed demographic information and measures of physical activity, positive body image (i.e., functional values, functional-behavioural investment, and functional satisfaction), embodiment, and self-objectification online or in person. Three separate serial mediation analyses (one for each positive body image outcome) were conducted using PROCESS Model 6 (Hayes, 2016) and 5000 bootstrap samples, with embodiment and self-objectification as the mediators.

Results: Results of the mediation analysis for functional values showed no direct or indirect effects (all $ps > 0.05$). For functional-behavioural investment, there was a significant total effect, $\beta = 0.21$, $t(140) = 2.58$, $p = .01$, and a significant direct effect $\beta = 0.23$, $t(138) = 2.74$, $p = .01$, but no significant indirect effects, $ps > 0.05$. For functional satisfaction, there was also a significant total effect $\beta = 0.29$, $t(140) = 3.53$, $p < .001$, a significant direct effect $\beta = 0.29$, $t(138) = 3.59$, $p < .001$, but no significant indirect effects, $p > 0.05$.

Conclusion: Results show that physical activity participation can contribute to positive body image in men. Specifically, there were increases in functional-behavioural investment (engagement in physical activities, reflecting importance of body function) and functional satisfaction (positive evaluation of the body's abilities). However, contrary to hypotheses, these effects were not mediated through embodiment and self-objectification; rather, the effects appear to be direct. Findings show that physical activity may affect positive body image differently for men than women. Further research is needed to understand how physical activity can enhance positive body image in men.

B. MOTIVATION AND BEHAVIOR CHANGE

Interactive Behavioural Support Interventions in Osteoarthritis Care: A Scoping Review

M. Wildekamp^{1,2}, F. Hoekstra^{2,3}, E.P. McCarthy⁴, N.J van der Vegt⁴, I. van den Akker-Scheek¹, J. Vrijzen¹

¹University Medical Center Groningen, Department of Orthopaedics, Groningen, Netherlands, ²The University of British Columbia, Centre for Chronic Disease Prevention and Management, Kelowna, Canada, ³The University of British Columbia, Department of Medicine, Division of Social Medicine, Vancouver, Canada, ⁴University of Groningen, Department of Human Movement Sciences, Groningen, Netherlands

Purpose: Physical activity (PA) offers essential benefits for adults with osteoarthritis (OA), yet PA levels remain low. Interactive behavioural support, such as counselling, shows promise in promoting PA. However, evidence regarding its design, delivery, and effectiveness — particularly for adults with OA or total joint prostheses — is limited and has not been systematically described. This scoping review aims to map and characterise interactive behavioural support interventions in these populations, examining their design, setting, delivery mode, theoretical foundations, and use of behaviour change techniques (BCTs).

Methods: A systematic search was conducted in PubMed, Embase, CINAHL, PsycINFO, and Web of Science (last updated September 3rd, 2025). Studies were eligible when they (1) included adults (≥18 years) with OA or a total joint prosthesis, (2) described interventions including interactive support aiming to increase PA or related determinants, (3) reported PA levels, determinants or user experiences, and (4) were published in English. Data were extracted using a template informed by the Behaviour Change Intervention Ontology, and BCTs were independently coded by two researchers using the updated BCT taxonomy.

Results: Thirty-four studies were included, most conducted in countries with relatively well-resourced healthcare systems, such as North America, Australia, and Europe. The majority (n=31, 91%) focused on adults with knee or hip OA, while only three studies (9%) specifically targeted adults with total joint prostheses. Interventions varied in design, delivery, and theoretical basis, yet consistent features emerged. Behavioural support was typically delivered individually by physical therapists or nurses and included on average seven BCTs, such as goal setting, delivering support, and goal strategizing. Almost all interventions (n=32, 94%) also included additional components, such as exercise programs or education.

Conclusion: Interactive behavioural support is commonly integrated with other intervention components and delivered using theory-informed approaches with key BCTs. There is considerable variation in design, delivery, and reporting, with interventions for adults with joint prostheses remaining limited. Future research should clarify the added value of interactive support within multicomponent programs, especially for adults with prostheses, explore implementation across less-resourced settings, and develop evidence-based guidelines to improve consistency, quality, and applicability of such interventions.

I-P-B.07

Cooking up Confidence: Impact of a 10-week Programme on Food Literacy in UK Secondary Schools

C. Uche^{1,2}, C. Evans¹, C. Auma¹, R. Bluett³, M. Tu³, J. Cade¹

¹University of Leeds, Nutritional Epidemiology Group, School of Food Science and Nutrition, Leeds, United Kingdom, ²Michael Okpara University of Agriculture Umudike, Human Nutrition and Dietetics, Abia, Nigeria, ³Jamie Oliver Group, London, United Kingdom

Purpose: Cooking skills are part of England's Design and Technology curriculum. Strengthening cooking skills and confidence can improve food literacy in terms of young people's ability to make healthy, informed food choices. This study assessed changes in food literacy including food and nutrition knowledge, cooking confidence and food skills of school pupils following participation in the 10-week Jamie Oliver Ministry of Food (MoF) school programme in Years 7–9.

Methods: Secondary schools (n=12) participated in the MoF programme between September 2023 and April 2024, with schools in underprivileged areas oversampled. The programme comprised ten 50-minute lessons (eight weeks if shortened), each involving meal preparation using fresh produce. At baseline and follow-up, 215 pupils from 12 schools completed cooking confidence and food literacy questionnaires (scored out of 70). Changes in food literacy between baseline and follow-up were analysed using multilevel regression modelling to consider the clustering of

B. MOTIVATION AND BEHAVIOR CHANGE

pupils within schools.

Results: Baseline food literacy was low (mean score 43/70). Knowledge gaps included identifying vitamins, minerals, and seasonal produce. Most pupils (98%) agreed cooking is important, but confidence varied: 67% felt very or extremely confident, while 6% lacked confidence in cooking from raw ingredients. After the programme, overall food literacy increased significantly (mean difference 3.0 points; 95% CI 2.0–3.9; $p < 0.001$), driven by improvements in knowledge (mean +1.7 points; $p = 0.003$) and cooking confidence (+0.9 points; $p = 0.03$). Two-thirds of pupils rated the course highly in terms of enjoying the meal (>4 out of 5), and 75% of pupils reported cooking at home using the course recipe post-programme.

Conclusion: The 10-week cooking programme significantly improved pupils' food knowledge and cooking confidence, demonstrating a positive impact on food literacy. Schools should integrate structured cooking lessons, engage parents, and provide take-home resources to improve food literacy and cooking confidence.

I-P-B.08

The Relationship between Environmental and Sustainability-related Literacy and Health-related Behavior: A Systematic Review

L. Paulsen¹, H. Muth¹, J. Kallenbach^{2,3}, L. Reismann³, C. Jochem³, J. Bucksch¹

¹Heidelberg University of Education, Faculty of Natural and Sociological Sciences, Department of Prevention and Health Promotion, Heidelberg, Germany, ²MSH Medical School Hamburg, University of Applied Sciences and Medical University, Faculty of Human Sciences, Department of Education, Hamburg, Germany, ³University of Bayreuth, Faculty of Law, Business & Economics, Chair of Planetary & Public Health, Bayreuth, Germany

Purpose: As environmental challenges increasingly affect human health, it becomes essential to understand how individuals' environmental knowledge, attitudes, and competencies influence their health-related behaviors (e.g., whether climate awareness promotes healthier eating). However, the association of environmental or sustainability-related literacy on health-related behaviors remains underexplored. This systematic review, therefore, addresses this research gap by identifying and synthesizing studies that examine this relationship.

Methods: The systematic review was conducted following PRISMA guidelines and was registered in PROSPERO (Registration ID: CRD420251104050). A comprehensive literature search was performed across databases from different research areas (e.g., PubMed, Web of Science, GreenFile) to identify studies examining the relationship between environmental or sustainability-related literacy and health-related behaviors. The search strategy included variations of 'environmental literacy' (e.g., climate literacy, green literacy) and 'health behavior' (e.g., 'healthy lifestyle' and 'physically active'). Inclusion and exclusion criteria were predefined (e.g., inclusion criteria like individuals who are capable of making conscious decisions or empirical studies measuring health behaviors, such as physical activity, healthy eating, and substance use), and data were extracted and synthesized narratively. Study quality was assessed using the JBI checklist for analytical cross-sectional studies.

Results: The database search identified 9,346 records. After removing duplicates and screening according to the eligibility criteria, five studies published within the past six years were included in the narrative synthesis. These studies, originating from the USA as well as Asian and European countries, varied in design, measurement instruments, quality, and conceptualization of literacy. Although all studies reported a statistically significant positive association between environmental or sustainability-related literacy and health-related behaviors (e.g., general health behavior, smoking, diet), no firm conclusions could be drawn regarding the direction of influence from environmental or sustainability-related literacy to health-related behaviors.

Conclusion: Findings suggest that environmental or sustainability-related literacy is linked to healthier behaviors. However, due to the limited number of studies, the heterogeneous understanding and measurement of literacy and the unclear direction of influence based exclusively on cross-sectional studies, further research is needed to better understand causal relationships and underlying mechanisms.

I-P-B.09

Environmental Literacy and Its Association with Health Behaviours in German Adolescents

J. Bucksch¹, J. Möckel¹, A. Lehmann¹, L. Paulsen¹

¹Heidelberg University of Education, Prevention and Health Promotion, Heidelberg, Germany

B. MOTIVATION AND BEHAVIOR CHANGE

Purpose: Health is closely linked to environmental and climate protection issues. The mutual benefits of health and the environment are evident and hold potential for making health-related and environmentally relevant decisions in a co-benefit scenario. However, empirical relationships between environmental literacy and health-related behaviours have rarely been examined.

Methods: The Health Behaviour in School-aged Children (HBSC) study surveyed 15-year-old girls (n=967) and boys (n=837) in the 2022 survey round, assessing their environmental literacy for the first time in the German sample. Environmental literacy was self-reported using an 11-item scale comprising the subdimensions knowledge, action, and social aspects. The associations of environmental literacy with self-reported fruit and vegetable consumption, as well as daily physical activity, were examined using sex-specific logistic regressions while controlling for family affluence and school type.

Results: In boys, the action dimension of environmental literacy was significantly associated in the adjusted model with daily fruit (OR: 1.32 [95%-CI: 1.14-1.54]) and daily vegetable consumption (OR: 1.30 [95%-CI: 1.09-1.56]), as well as with meeting physical activity recommendation (OR: 1.32 [95%-CI: 1.23-1.54]). The social dimensions show similar results for daily fruit consumption and physical activity. In girls, we found significant associations between the knowledge (OR: 1.36 [95%-CI: 1.11-1.66]) and action dimension (OR: 1.23 [95%-CI: 1.04-1.46]) of environmental literacy and daily fruit consumption. The total score of environmental literacy was significantly associated with daily fruit consumption in both boys and girls, and with physical activity in boys only.

Conclusion: We found selected associations between different dimensions of environmental literacy and fruit and vegetable consumption, as well as with physical activity. The findings indicate co-benefits between sustainability and health behaviours, offering a new perspective for designing interventions. Promoting environmental literacy in education could simultaneously foster healthier behaviours among adolescents. The underlying mechanism explaining the association between environmental literacy and health behaviours should also be further investigated.

I-P-B.10

Motivational Interviewing Plus Cognitive Behavioral Therapy Interventions on Physical Activity among Adults: A Systematic Review and Meta-analysis

H.O. Fawole^{1,2,3}, D.F. Bolarin¹, F.O. Kolawole^{1,2}, A.O. Yakubu^{1,2}, G. Orah^{1,2}, B. Eromosele^{1,2}, O. Akinrolie^{2,4}

¹University of Benin, Physiotherapy, Benin, Nigeria, ²Emerging Researchers and Professionals in Ageing-African Network, Abuja, Nigeria, ³Coventry University, Physiotherapy, Coventry, United Kingdom, ⁴University of Calgary/Lifespan Brain Health Lab, Psychology, Calgary, Canada

Purpose: The World Health Organization (WHO) projects that global physical inactivity levels will rise to 35% by 2030, demonstrating that current efforts are insufficient to achieve the WHO's goal of a 15% reduction in physical inactivity within this period. This growing gap underscores the need for effective behavioral interventions that can enhance motivation and adherence to physical activity. Motivational interviewing (MI) and cognitive behavioral therapy (CBT) have emerged as promising strategies for addressing barriers to engaging in physical activity. Using both behavioral techniques could complement each other and maximize their potency. Therefore, this systematic review aimed to determine the effectiveness of MI + CBT in promoting physical activity among adults.

Methods: Cochrane library, Medline, PsycINFO, CINAHL, EMBASE and Web of Science core collections databases were searched from inception to 16th July, 2025. Eligible studies included randomized controlled trials (RCTs) which examined the effects of MI+CBT on physical activity (primary outcome), quality of life and self-efficacy (secondary outcomes) in adults (≥18 years). Risk of bias was assessed using the Cochrane RoB-2, and certainty of evidence with Grading of Recommendations, Assessment, Development and Evaluation. Pooled data was summarized with standardized mean difference (SMD) using a random-effects model.

Results: Of the 404 studies retrieved, only five RCTs were included in this review with a total sample size of 2,146 adults (age range 18-71 years; 75% male). The results showed that combined MI+CBT interventions had a non-significant effect on physical activity (SMD = -0.54, 95% CI [-0.07 – 1.16], I²=86%, p=0.08) and quality of life (SMD = -0.76, 95% CI [-1.51 – 3.03], I²=95%, p=0.51) with very low certainty of evidence. However, there was a moderate certainty of evidence supporting the beneficial effect of MI + CBT on self-efficacy (SMD = 0.33, 95% CI [0.09, 0.56], I² = 0%, p = 0.007).

Conclusion: Although MI + CBT intervention had no statistically significant improvement on physical activity and quality of life, but it demonstrated moderate evidence for the beneficial effects on self-efficacy among adults. Strengthening self-efficacy may therefore serve as a pivotal pathway for improving adherence and achieving meaningful increase in physical activity participation among adults.

B. MOTIVATION AND BEHAVIOR CHANGE

Are Pre-operative Exercise Interventions for Joint Arthroplasty Effective at Improving Peri-operative Outcomes: A Systematic Review and Meta-analysis of Randomized Controlled Trials

N. Hares¹, J. Sanders¹, D. Esliger¹, J. Thomas², B. Bourron¹, H. MacKinnon³, C. Madigan¹

¹Loughborough University, School of Sport, Exercise and Health Sciences, Leicestershire, United Kingdom, ²University of Leicester, Leicester Diabetes Centre, Leicestershire, United Kingdom, ³University Hospitals of Leicester, Fit4Surgery Prehabilitation Team, Leicestershire, United Kingdom

Purpose: Evidence on pre-operative physical activity before hip and knee arthroplasty is limited and heterogeneous, meanwhile intervention components and behavior change techniques remain underexplored. This review examined the effectiveness of pre-operative physical activity interventions on patient and surgical outcomes in elective hip and knee arthroplasty up to 12 weeks post-surgery.

Methods: A systematic search of 8 databases up to August 8, 2024 identified randomized controlled trials of physical activity interventions before total hip and knee arthroplasty. Quality of evidence was evaluated with Grading of Recommendations, Assessment, Development and Evaluation (GRADE) framework. Random-effects models were used for meta-analyses. The included interventions were described using the Template for Intervention Description and Replication (TIDieR) and behaviour change techniques (BCTs) were identified via the Behaviour Change Technique Taxonomy (BCTTv1).

Results: Forty trials were included. Significant mean differences in favour of the intervention groups were found at pre- and post-surgery in 4 outcomes: health-related quality of life (Knee pre-surgery SMD = -0.5, 95%CI: -0.1 to -0.1 and Hip and Knee post-surgery SMD = -0.4, 95%CI: -0.6 to -0.1), pain (Hip and Knee pre-surgery SMD = -0.4, 95%CI: -0.6 to -0.1 and Knee post-surgery SMD = -0.3, 95%CI: -0.6 to -0.1), function (Hip and Knee pre-surgery SMD = -0.5, 95%CI: -0.8 to -0.2 and Knee post-surgery SMD = -0.6, 95%CI: -1 to -0.2), and timed-up-and-go (Hip and Knee MD = -1.2, 95%CI: -2 to -0.3 and Hip and Knee MD = -1.3, 95%CI: -1.7 to -0.8). Half of the interventions reported over 75% of the TIDieR items, while behavior change techniques reporting was limited.

Conclusion: Pre-operative exercise improves health-related quality of life, pain, and function pre- and post-surgery in elective hip and knee arthroplasty. Standardized reporting is needed for establishing effective intervention components.

I-P-B.14

Women in Strength: Randomised Controlled Feasibility Testing of a Co-designed Muscle-strengthening Intervention for Women

N.D. Rosaini¹, G.C. Ryde¹, S.R. Gray¹

¹University of Glasgow, School of Cardiovascular and Metabolic Health, Glasgow, United Kingdom

Purpose: Women's participation in muscle-strengthening exercise remains low despite its known health benefits. A prior workshop identified barriers, facilitators, and co-designed an intervention for women not currently participating in these activities. This study aimed to assess the feasibility and effects of a co-designed muscle-strengthening exercise intervention for women.

Methods: We recruited women aged 18–45 years. The initial 12-week intervention included education sessions, optional group exercise sessions, online support group, training logs, and access to various modalities (gym memberships and resistance bands). Participants were encouraged to complete two weekly muscle-strengthening sessions of their choice (weights, resistance bands, bodyweight, yoga, Pilates, or strength classes). After 12 weeks, support was withdrawn, and participants were asked to maintain twice-weekly sessions. The control group maintained habitual activity. Feasibility was assessed through recruitment, adherence and retention at 24 weeks. Acceptability was evaluated via qualitative interviews and analysed thematically. Measurements included muscle thickness, handgrip strength, back strength, and knee extensor torque at baseline, 6, 12, and 24 weeks.

Results: Thirty-one participants completed (n=16 control; n=15 intervention; age 28.9 ± 7.6 years). Recruitment targets were met (100%), with 91% retention and 53% completed ≥24 sessions within 12 weeks. Education sessions (attendance 80–87%) and access to exercise modalities were highly acceptable. Optional group sessions and the online support group were less utilised. No significant interactions were observed. Significant effects of time occurred for muscle thickness (p=0.028), back strength (p=0.039), and knee extensor torque (p<.001), but not handgrip strength

B. MOTIVATION AND BEHAVIOR CHANGE

($p=0.118$). From baseline to week 12, changes in muscle thickness were +0.56mm, $p=0.492$ in control and +0.86mm, $p=0.054$ in intervention. For handgrip strength, changes were -0.75kg, $p=1.000$ in control and +0.17kg, $p=1.000$ in intervention. For back strength, changes were +3kg, $p=1.000$ in control and +9.8 kg, $p=0.011$ in intervention. For knee extensor torque, changes were -0.52Nm, $p=1.000$ in control and +10.89Nm, $p=0.381$ in intervention. Similar results were observed from baseline to week 24, with effects generally smaller.

Conclusion: The co-designed muscle-strengthening intervention was feasible, acceptable, and showed potential for improving muscle thickness and strength. These findings suggest the trial was successful and can be advanced to a larger trial focusing on increasing adherence.

I-P-B.15

Inconsistent Association Pattern between Health and Well-being Determinants and the Day-to-Day Variability of Sedentary Behaviour in Community Dwelling People with Stroke

L. Oirschot, van^{1,2}, W. Hendrickx^{2,3,4}, M.F. Pisters^{2,3,4}

¹Utrecht University, Clinical Health Sciences, Utrecht University Medical Center, Utrecht, Netherlands, ²Fontys University of Applied Sciences, Department of Health Innovations and Technology, Research Group Empowering Healthy Behavior, Eindhoven, Netherlands, ³University Medical Centre Utrecht, Department of Rehabilitation, Physiotherapy Science & Sport, UMC Utrecht Brain Centre, Utrecht, Netherlands, ⁴Centre for Physiotherapy Research and Innovation in Primary Care, Julius Health Care Centres, Utrecht, Netherlands

Purpose: Stroke is the second leading cause of death and the third leading cause of long-term disability worldwide and people who suffered a stroke are at high risk of a recurrent stroke. This makes secondary prevention after stroke highly important. The risk of stroke is associated with high levels of sedentary behaviour. Therefore it is important to improve the effectiveness of behaviour interventions aiming to reduce sedentary behaviour in people with stroke. The current study aimed to explore the association between health and well-being determinants and the daily variability in sedentary behaviour over time within community-dwelling people with stroke.

Methods: In this n-of-1 study design the associations between determinants and sedentary behaviour during the RISE-intervention randomized multiple baseline study was examined. Sedentary behaviour was measured with an accelerometer for 17.5 weeks. health and well-being determinants were measured daily using the Visual Analogue Scale. Dynamic regression modelling (time-series analysis) was used to determine the association between health and well-being determinants and daily variability in sedentary behaviour over time.

Results: Data from twelve community dwelling people with stroke (median age 65, daily sedentary behaviour ranging 55.5-81.4 percent) were included in the analysis. It showed variance in the associations between participants. Sleep length (measured with the activity monitor) was positively associated with the percentage of sedentary behaviour in three participants ($p=0.001$, $p<0.0001$, $p=0.045$), and negatively associated in one participant ($p=0.002$). Subjective sleep length ($p=0.016$), fatigue ($p=0.013$), and pain ($p=0.0098$) were exclusively associated with the percentage of sedentary behaviour in one participant. No significant associations were found for sleep quality, happiness, stress, or time pressure in any of the participants.

Conclusion: The results of this study show an inconsistent association pattern between health and well-being determinants and the day-to-day variability of sedentary behaviour across participants. Indicating that factors associated with the daily variability of sedentary behaviour in one individual may differ from those in another individual. This highlights the need for a personalized approach within behavioural interventions aiming to improve sedentary behaviour in people with stroke.

I-P-B.16

Towards the Co-design of a Culturally Relevant Physical Activity Intervention for Adults at Higher Risk of Non-communicable Diseases: Application of a Behavioural Science Approach

A. Cadri¹, T. Barnett¹, S. Bacon², P. Bush¹, K. Lavoie³, K. Wassef¹, N. Alberts², M. Aubertin-Leheudre³, C. Trudel-fitzgerald⁴, S. Lambert⁵, R. Nikolopoulos¹, G. Abotsem Abiir⁶, S. Apanga⁶, P. Kanyiri Gaa⁶, V. Mogre⁶, L. Gauvin⁷, A. Belanger-Gravel⁸

B. MOTIVATION AND BEHAVIOR CHANGE

¹McGill University, Family Medicine, Montreal, Canada, ²Concordia University, Montréal, Canada, ³Université du Québec à Montréal, Montreal, Canada, ⁴Université du Québec à Trois-Rivières, Trois-Rivières, Canada, ⁵McGill University, Ingram School of Nursing, Montréal, Canada, ⁶University for Development Studies, Tamale, Ghana, ⁷Université de Montréal, Montréal, Canada, ⁸Université Laval, Quebec City, Canada

Purpose: Engaging stakeholders in co-design ensures interventions are culturally relevant, contextually appropriate, and more likely to be adopted and sustained in real-world settings. We describe the first step of the process of co-designing a theory-informed PA intervention to be delivered in primary care (PC) for adults at higher risk of NCDs, in Ghana and Canada.

Methods: Our co-design process includes 2 steps:

- i) developing an initial theory-informed core version of the intervention, and
- ii) adapting the intervention to country-specific PC contexts with Ghanaian and Canadian stakeholders.

To date we identified relevant systematic reviews, extracted the reported determinants, and mapped them onto the Theoretical Domains Framework (TDF) and Behaviour Change Wheel components (Capability, Opportunity, Motivation, and Behaviour). Subsequently, we selected relevant Behaviour Change Techniques (BCTs) to target identified determinants and their likely Mechanisms of Actions. Finally, we applied the APEASE criteria (Acceptability, Practicability, Effectiveness, Affordability, Side-effects, and Equity) to the selected BCTs.

Results: The identified determinants were mapped onto 12 TDF domains: knowledge (adequate PA literacy and knowledge); behavioural regulation (establishing healthy PA routines); skills (practical skills on PA); social influences (positive social support for PA); environment context and resources (supportive built environment); social role and identity (competing roles resulting in lack of time for PA); beliefs about capabilities (positive belief about capabilities); belief about consequences (belief that PA will improve health); and emotion (pleasure engaging in PA). Relevant BCTs related to goal setting, action planning, self-monitoring of behaviour, feedback on performance, social support and instruction on how to perform PA. Education, training, enablement, and persuasion were identified as the most effective intervention functions to activate to promote PA in PC. Using these results as a starting point, together with ongoing work including comprehensive systematic reviews on PA determinants and implementation strategies, and patient and clinician perspectives on promoting PA in PC settings, we are now using co-design methods to adapt the intervention and develop the implementation plan with our transdisciplinary team of stakeholders.

Conclusion: The first step of a co-design process aiming to develop a theory-informed core version of the intervention requires substantial teamwork and involves multiple iterations between theoretical content and intervention aims.

I-P-B.17

Psychosocial Correlates of Mediterranean Diet Adherence across Time: A Secondary Analysis of the BRIDGE Study

Y. Soto¹, M. Lamar², L. Schiffer³, L. Blumstein³, L. Tussing-Humphreys⁴, M. Fitzgibbon⁴, A. McLeod⁵

¹University Of Illinois Chicago, Department Of Medicine, Chicago, United States, ²Rush Medical College, Department of Psychiatry and Behavioral Sciences, Division of Behavioral Sciences, Chicago, United States, ³University of Illinois Chicago, Institute for Health Research and Policy, Chicago, United States, ⁴University of Illinois Chicago, Institute for Health Research and Policy, University of Illinois Cancer Center, Department of Kinesiology and Nutrition, Chicago, United States, ⁵University of Illinois Chicago, Chicago, United States

Purpose: Adherence to the Mediterranean diet (MedDiet) is associated with improved cardiometabolic and cognitive outcomes, yet the psychosocial factors supporting sustained adherence remain unclear. Guided by Self-Determination Theory, this secondary analysis of the BRIDGE dataset examined how motivation and depressive symptoms predict Mediterranean diet adherence trajectories across three intervention groups and multiple timepoints.

Methods: Data were drawn from the BRIDGE randomized controlled trial evaluating behavioral strategies to promote Mediterranean diet adherence among adults (N = 185) assigned to one of three groups: 1) MedDiet education only, 2) MedDiet plus calorie restriction, or 3) control. Mediterranean diet adherence was assessed using the 14-item Mediterranean Diet Adherence Screener (MEDAS). Depressive symptoms were measured with the Center for Epidemiologic Studies Depression Scale (CES-D), physical activity with the Godin Leisure-Time Exercise Questionnaire, and motivational regulation with the Treatment Self-Regulation Questionnaire (TSRQ). A linear mixed-effects model was estimated to assess psychosocial predictors of MedDiet adherence over time, with participants modeled as a random intercept. Fixed effects included depression, physical activity, autonomous motivation, controlled motivation, and amotivation, along with time point, group, and their interaction.

Results: Autonomous motivation was positively associated with Mediterranean diet adherence ($\beta = 0.39$, SE = 0.14, $p = .005$). Depressive symptoms, physical activity, controlled motivation, and amotivation were not significant predictors.

B. MOTIVATION AND BEHAVIOR CHANGE

Adherence increased linearly across visits ($p < .001$), with a quadratic trend indicating that gains plateaued over time ($p < .001$). Compared with the MedDiet-only group, the control group showed lower overall adherence ($\beta = -0.82$, $SE = 0.25$, $p = .001$). The MedDiet-plus group did not significantly differ from MedDiet-only in overall adherence or change patterns.

Conclusion: Autonomous motivation emerged as a key psychosocial predictor of Mediterranean diet adherence, suggesting that fostering self-endorsed motivation may enhance long-term dietary engagement. Although adherence improved over time, gains plateaued, highlighting the need for sustained behavioral support. Group differences suggest that intervention intensity and delivery context may influence adherence trajectories. These findings advance understanding of motivational mechanisms underlying Mediterranean diet adoption and maintenance in behavioral nutrition research.

I-P-B.18

Boosting Everyday Movement: Co-designing an Intervention to Promote Micropatterns among Diverse Communities

M. Bissett¹, N. Koemel^{2,3}, M. Ahmadi^{2,3}, K. Atsiaris^{2,3}, S. Liu⁴, C. Thøgersen-Ntoumani^{5,6}, C. Gray⁷, J. Gill¹, E. Stamatakis^{2,3}, G. Ryde¹

¹University of Glasgow, School of Cardiovascular and Metabolic Health, Glasgow, United Kingdom, ²University of Sydney, Mackenzie Wearables Research Hub, Sydney, Australia, ³University of Sydney, School of Health Sciences, Sydney, Australia, ⁴University of Victoria, School of Exercise Science, Victoria, Canada, ⁵University of Southern Denmark, Danish Centre for Motivation and Behaviour Science (DRIVEN), Odense, Denmark, ⁶University of Birmingham, School of Sport, Exercise and Rehabilitation Sciences, Birmingham, United Kingdom, ⁷University of Glasgow, School of Social and Political Sciences, Glasgow, United Kingdom

Purpose: Vigorous (VILPA) and moderate to vigorous (MV-ILPA) intermittent lifestyle physical activity are defined as brief bouts of physical activity occurring during normal daily activities lasting <1 minute and <3 minutes respectively. Evidence indicates that 4-6 bursts of VILPA/MV-ILPA per day can lead to a significant reduction in risk from cardiovascular disease and some cancers. These “micropatterns” of activity may offer a time-efficient and accessible alternative to the temporal and financial barriers (e.g. equipment) associated with structured exercise. However, communities will still experience unique barriers and facilitators to VILPA/MV-ILPA that need to be explored. This research aims to explore participant perspectives and experiences of VILPA/MV-ILPA and co-design a digital intervention to promote these activities among socioeconomically diverse communities in Glasgow and Sydney.

Methods: The study involved a series of three co-design workshops in Glasgow (N=20) and Sydney (N=34). Workshops incorporated participatory activities, education, training, discussion, and reflection to explore the concept of micropatterns, related facilitators and barriers and co-design the intervention. This study was guided by the Behaviour Change Wheel and MRC and 6SQiD intervention development frameworks. Data were audio-recorded, transcribed, and analysed using thematic framework analysis.

Results: Participants identified a range of barriers (e.g. concerns about ability and safety, low mood, sociocultural norms) and facilitators (e.g. adaptability, dual-purpose activities, minimal time commitment) to engaging in micropatterns. Thirteen intervention components were identified that utilized seven intervention functions (education, persuasion, training, environmental restructuring, modelling, incentivisation, and enablement) to promote VILPA/MV-ILPA activities. The importance of educational content, social support, accessible terminology and inclusive delivery formats (e.g. short videos, visual materials) were emphasised in both contexts.

Conclusion: The co-design process shaped the development of a highly promising app-based digital intervention to promote VILPA and MV-ILPA among diverse communities. This study will provide critical insights to support the successful real-world implementation of micropattern interventions in future research and practice.

Perspectives of Nurses on their Role in Supporting an Active Lifestyle during Inpatient Stroke Rehabilitation

A. Mennema¹, J. Meesters^{1,2}, L. Hollander², A. De Rooij¹, J. De Man - Van Ginkel³, J. Dikken², L. te Lindert⁴

¹Basalt Rehabilitation Center, Innovation, Quality + Research, The Hague, Netherlands, ²The Hague University of Applied Sciences, Center of Expertise in Health Innovation, The Hague, Netherlands, ³Leiden University Medical Centre, Academic

B. MOTIVATION AND BEHAVIOR CHANGE

Nursing & Department of Gerontology and Geriatrics, Leiden, Netherlands, ⁴Basalt Rehabilitation Center, The Hague, Netherlands

Purpose: Although enhancing physical activity (PA) is important for physical and cognitive recovery of stroke patients, the role of nurses in supporting an active lifestyle is underused during the inpatient rehabilitation treatment. The aim of this study is to identify nurses' perspectives on their current and potential role and influencing factors to support an active lifestyle of stroke patients during inpatient rehabilitation treatment.

Methods: Three focus groups were conducted in three Dutch rehabilitation centres with 18 nurses (EQF level 3-6 (European Qualifications Framework)). Each focus group consisted of 5-8 nurses. The transcribed data were analysed using the framework method. The data were coded by 2 researchers independently and afterwards checked to align the codes and themes until consensus was reached.

Results: In their current role, nurses encourage PA during the 24/7 nursing care with a focus on regaining independency. In their potential role, nurses consider themselves the linking pin between the patient, nursing team and interdisciplinary team. They have unique knowledge of patients through their 24/7 eyes on the patients and (informal) contact with relatives. Nurses foresee a shift towards coaching and supporting patients to achieve a more active lifestyle.

The influencing factors mentioned by nurses can be divided into five themes: awareness of nurse's role, structures supporting patients' active lifestyle within nursing practice, changing work patterns, social interactions within nursing team, and profiling the nurse's role within interdisciplinary team.

Conclusion: Nurses may have a large potential role in promoting an active lifestyle of patients during inpatient rehabilitation. Their current role in facilitating and coaching patients to regain independency can be expanded to facilitating and coaching patients in behavioural change toward an active lifestyle.

However, nurses need support in learning how to improve their role in supporting an active lifestyle. Increasing their role also priority with nurses and in the nursing teams, structure within nursing practice and, requires commitment from the interdisciplinary team.

I-P-B.20

From Farm to Table, Not to Trash: A Community Approach to Reducing Food Waste

D.K. Smith¹

¹*Washington State University, CAHNRS Youth and Family, Skagit County Extension, United States*

Purpose: The purpose of this work is to empower households to reduce food waste through education, engagement, and practical tools. The projects objectives were to:

1. Increase awareness of food waste impacts and actionable solutions among households in Skagit County
2. Motivate community members to adopt at least one new food waste prevention behavior.
3. Foster community partnerships to sustain and expand food waste prevention efforts.

Methods: A community-based qualitative evaluation employed a participatory action approach to assess the impacts of the campaign. The initiative sought to understand household behavior change linked to food waste reduction and its contributions to climate action. The campaign targeted Skagit County households, including bilingual (English and Spanish) families and local community partners.

Qualitative data were collected through participant-generated feedback on a "Wall of Ideas" during the community event, capturing firsthand accounts of household behavior changes. Additional feedback came from reflections of team members and partners during a ripple effect mapping session.

Indicators included self-reported behavior changes (e.g., improved food storage, composting adoption, meal planning), number of individuals reached, and estimated pounds of food diverted from landfills. Qualitative data were analyzed thematically following a grounded theory approach, identifying recurring patterns in participant behaviors and attitudes toward waste prevention. Quantitative engagement data was summarized descriptively to assess program reach and behavioral adoption trends.

Results: Results. Broad community engagement and measurable behavior changes aligned with the food waste prevention and climate action goals of the project

The campaign's bilingual outreach materials and events reached more than 10,000 county residents through digital, print, and broadcast media. Social media posts in English and Spanish generated over 1,800 engagements and 300 webpage clicks. The "Day of Learning" attracted 120 in-person participants, and over 6,000 residents were reached through print newspaper coverage and 10,000 through public radio and television features.

Conclusion: The program has proven that practical, accessible education, when adapted to local contexts and

B. MOTIVATION AND BEHAVIOR CHANGE

cultures, can significantly reduce food waste and strengthen community engagement around climate action. The ongoing integration of these approaches within Skagit County reflects the power of Extension-led collaboration to create sustainable, system-level change that benefits both people and the planet.

I-P-B.21

Exercise Identity and Resilience in Physical Activity: Revealing New Insights into Women's Motivation and Barriers

M. Lacoursière¹, S. Girard¹, S. Stoloff¹

¹Université du Québec à Trois-Rivières, Department of Human Kinetics, Trois-Rivières, Canada

Purpose: Living in remote regions limits access to physical activity, and women in these areas show lower participation rates (INSPQ, 2022). Psychological factors, including exercise identity, reflecting integrating activity into one's self-concept, and resilience in physical activity, the ability to overcome participation challenges, may help counter these barriers. Both have been associated with sustained engagement in exercise (Martin et al., 2025; Wilson et Muon., 2008). This study compared the proportions of adolescent girls (12-17 years) and young adult women (18-29 years) practicing physical activity by cross-referencing their exercise identity and resilience in physical activity with reported motivations and barriers.

Methods: Data came from the 2018–2019 *Enquête québécoise sur l'activité physique et le sport* (EQAPS), a population-based survey conducted across Québec ($n = 17,649$). The subsample included 6,177 females (5,334 adolescents; 843 young adults). Twenty-four closed-ended items from two sections – *opinions, perceptions and values regarding physical activity* and *respondent profile* – were analyzed. Weighted analysis (SAS, SUDAAN) used log-linear chi-square and Wald tests ($p < .05$) to compare proportions; estimates were assessed via coefficient of variation.

Results: Across age groups, differences in motivations and perceived barriers were observed according to exercise identity and resilience. The highest proportions of perceived barriers appeared among adolescents declaring no exercise identity nor resilience, whereas those declaring both reported a broader range of motivations. Both adolescents and young adults declaring exercise identity alone reported higher competition-related motivation (84.6% and 78.2%; $p < .05$). Among adolescents, nine out of ten perceived barriers showed lower proportions among those declaring exercise identity and resilience. Specifically, adolescents declaring having resilience alone reported lower proportion of “lack of a partner” (24.4% vs. 43.8%; $p < .05$) as a perceived barrier, whereas those declaring exercise identity and resilience mentioned more often “health issue or injury” (32.6% vs. 25.8%; $p < .05$).

Conclusion: Strengthening both exercise identity and resilience among women during adolescence and young adulthood appears as a potential lever for improving their engagement in physical activity. Future interventions should explore how combining these constructs may reduce participation barriers and enhance motivation, especially among women in rural and remote areas.

I-P-B.22

Faster Walking Pace, Fewer Steps: Consequences of Time-restricted Outdoor Periods in Older Adults during the Pandemic in Spain

V. Castillo Antúnez¹, J.C. Benavente-Marín¹, O. Fernández Barceló¹, E. Crespo Oliva¹, J. Barón López¹, N. Pérez-Farinós^{1,2}, J. Wärnberg^{1,2}

¹EpiPHAAN Research Group. School of Health Sciences, University of Málaga - Instituto de Investigación Biomédica en Málaga (IBIMA Plataforma Bionand), Málaga, Spain, ²Centro de Investigación Biomédica en Red. Fisiopatología de La Obesidad y La Nutrición (CIBEROBN), Institute of Health Carlos III, Madrid, Spain

Purpose: The political restrictions to control mobility and reduce epidemiological risk during the COVID-19 pandemic led to changes in physical activity habits. The aim of the study was to analyze changes in physical activity patterns in general, and walking in particular, before, during, and after the pandemic, taking into account the time restrictions imposed during the de-escalation phase in Spain.

Methods: A longitudinal study was conducted with 50 overweight or obese older adults (62–76 years) residing in Benalmadena, Spain. Three periods were evaluated: pre-pandemic (T1), pandemic-de-escalation (T2), and post-pandemic (T3). Physical activity was measured using wrist accelerometers (GENEActiv) worn for seven consecutive days. Step count, cadence, mean intensity (ENMO), moderate-to-vigorous physical activity (MVPA bouts)

B. MOTIVATION AND BEHAVIOR CHANGE

and walking patterns were compared.

Results: In both sexes, total daily steps decreased from T1 to T2 (9109 to 7527 steps/day).

In men, walks were shorter in T2 (37.6 min/day) compared to T1 (42.2 min/day), and continued to decrease in T3 (30.5 min/day). However, the walks in T2 had faster pace and were more intense, with the highest cadence (84 steps/min) and mean ENMO (128.1 mg) values.

In women, the duration of walks was also shorter in T2 (20.6 min/day) compared to T1 (22.7 min/day) but increased again in T3 (25.0 min/day). During the evening walks in T2, the fastest paces were recorded (86.6 steps/min), while the most intense walks, with the highest ENMO value, corresponded to the morning walks in T3 (97.3 mg). Overall, these findings suggest that the pandemic did not increase their frailty; on the contrary, the women regained and even surpassed their pre-pandemic activity levels.

Conclusion: The pandemic led to a redistribution of walking time and intensity, with differences between sexes. Time slots served as a facilitating structure for daily routines. These changes may have supported the maintenance of mobility and functional health, particularly among women.

I-P-B.23

Motivational Interviewing Skills in a Hospital-based Lifestyle Front Office: Association with Patients' Successful Behavioral Change

L.M. Te Loo^{1,2,3}, J.F. Holla¹, A. Driessen^{2,3}, M.L. Van Dijk^{2,3,4}, C. Schumacher⁵, J. Vrijzen⁵, I. Van den Akker-Scheek⁵, R. Dekker⁶, H. Van der Ploeg^{2,3}, W. Van Mechelen^{2,3}, J.G. Jelsma^{2,3,4}, LOFIT-consortium

¹Inholland University of Applied Sciences, Faculty of Health, Sports and Social Work, Haarlem, Netherlands, ²Amsterdam UMC, Department of Public and Occupational Health, Amsterdam, Netherlands, ³Amsterdam Public Health Research Institute, Health Behaviors & Chronic Diseases, Amsterdam, Netherlands, ⁴Amsterdam Public Health Research Institute, Quality of care, Amsterdam, Netherlands, ⁵University of Groningen, University Medical Center Groningen, Department of Orthopedics, Groningen, Netherlands, ⁶University of Groningen, University Medical Center Groningen, Department of Rehabilitation, Groningen, Netherlands

Purpose: Motivational Interviewing is a communication style which helps overcome ambivalence and strengthens internal motivation for lifestyle change. This study aimed to 1) evaluate Motivational Interviewing (MI) fidelity of nine lifestyle brokers working in the Lifestyle Front Office (LFO) during the Dutch Lifestyle front Office For Integrating medicine in the Treatment of patients (LOFIT)-trial, and 2) examine the associations between lifestyle brokers' MI-scores and patient behavioral outcomes.

Methods: During the LOFIT-trial, all MI consultations in the LFO were audio-recorded. For each lifestyle broker, at least four recordings were randomly selected and independently scored by two researchers using the Motivational Interviewing Treatment Integrity code (MITI), version 4.2.1. This resulted in two global summary scores (global technical (GT) and global relational (GR), range 1-5) and four behavioral scores (% complex reflections (%CR), Reflection-Question-ratio (RQR) and the counts of MI-adherent behavior (MIA) and MI-nonadherent behavior (MINA)). Summary MI-scores were averaged per lifestyle broker and compared with established threshold values to evaluate MI fidelity.

Linear regression analyses were conducted with as independent variable the dichotomized MI scores of each lifestyle broker (low or high quality), and as dependent variable patients' FUSTER BEWAT score.

Results: Mean weighted summary scores (range; threshold score) were GT 3.5 (1.9-4.4; 3.0); GR 3.6 (1.9-4.3; 3.5); %CR 40.2% (14.3-61.2%; 40%) RQR 1.0 (0.3-1.8; 1.0) MIA 3.8 (2.0-5.2; n/a) MINA 2.0 (0.1-9.5; n/a)

Average summary scores met or exceeded threshold values, indicating that MI fidelity was achieved within the LOFIT trial. Considerable variation was observed between lifestyle brokers (5= high MI; 3= low MI).

The analysis between MI fidelity and the Fuster-BEWAT-score showed a nonsignificant mean difference of 1.09 (95%CI -0.37 to 2.56).

Conclusion: This study evaluated professionals' fidelity to a MI protocol within an RCT, supporting the interpretation of the trial results. Investigating the associations between MI quality and behavioral outcomes (Fuster-BEWAT) provides valuable insight into the urgency of using motivational interviewing in lifestyle care.

B. MOTIVATION AND BEHAVIOR CHANGE

'I Must Admit, I'm Still Having Ice Cream.' – Motivational Interviewing and Dietary Health Behaviour Change Talk in Type 2 Diabetes Community Healthcare

H. Meyer¹, K. Ekberg², G. Healy¹, S. Gomersall¹

¹The University of Queensland, School of Human Movement and Nutrition Sciences, Brisbane, Australia, ²Flinders University, College of Nursing and Health Sciences, Adelaide, Australia

Purpose: The way healthcare professionals and patients discuss dietary health behavior change can impact patient health outcomes and the patient's experience of healthcare. Motivational Interviewing (MI) is a communication practice known to improve behaviour change outcomes. Despite being a best practice approach, dietary behaviour change talk in practice using MI approaches has been scarcely studied to date. The purpose of this study was to examine how dietitians functionally achieve dietary behaviour change talk during the dietary history-taking phase of consultations with people with type 2 diabetes.

Methods: This study used the qualitative method of conversation analysis (CA), which focuses on language use in an interaction, examining the context beyond what is being said. Fifteen hours of naturally occurring, video-recorded dietitian-client consultations were transcribed verbatim and analyzed line by line to identify interactional patterns within the data. Using CA, we focused on the functional language used by the dietitian and its alignment with motivational interviewing (MI) practices. The study examined the specific strategies used by the dietitian and client to solicit and provide dietary information, ultimately leading to the clinical negotiation of dietary behaviour change.

Results: In the dietary history-taking phase of the consultations, two themes were identified.

1. Clients often disclose negative assessments of themselves (self-deprecations) and their dietary choices or moralistic food talk in response to the dietitian's questioning. E.g., *Client: "I was naughty yesterday, I had three hot chocolates."*
2. The Dietitian's response (employment of MI or not) to these accounts and moralistic disclosures impacts clients' in situ acceptance of subsequent dietary and/or behavioural advice. E.g. *Client: "I am guilty of getting fried chicken!" Dietitian: "That's fine!" Client: "I'll remember that!" Dietitian: "That's protein, I'm happy you're getting it."*

Conclusion: This study contributes to a deeper understanding of the use of MI in dietetic practice and how dietitians' questioning style can affect clients' acceptance of dietary behaviour change advice in situ. Findings from this study have the potential to inform future MI training curricula for dietary health professionals. Optimising the use of MI in clinical settings may improve dietary behaviour change conversations and subsequent dietary health outcomes.

I-P-B.25

Health by Association: A Cluster-based Analysis of Personal Social Networks and Health Behaviours

T. Nelson¹, A. Bélanger-Gravel², M. Henderson^{3,4,5}, T. Schuster¹, A. Van Hulst⁶, T. Barnett¹

¹McGill University, Family Medicine, Montreal, Canada, ²Université Laval, Département d'Information et de Communication, Quebec City, Canada, ³Université de Montréal, Département de Pédiatrie, Montreal, Canada, ⁴Université de Montréal, School of Public Health, Department of Social and Preventive Medicine, Montreal, Canada, ⁵Centre de Recherche CHU Sainte-Justine, Montréal, Canada, ⁶McGill University, Ingram School of Nursing, Montreal, Canada

Purpose: To identify distinct personal social network (PSN) phenotypes and explore their association with physical activity (PA) and dietary behaviours.

Methods: Data were from Wave 4 of QUALITY, an ongoing cohort study on cardiometabolic health. Participants (*egos*) aged 23–29 years completed an online questionnaire assessing PSNs and health behaviours. *Egos* were prompted to: name significant persons in their PSN (*alters*), describe relationship characteristics with and between *alters*, and report sociodemographics and health behaviours for themselves and *alters*. A diet quality score was computed based on the average of three diet items coded 1=unhealthy to 5=healthy. Scores were categorized as diet quality ≥ 4 (*healthy*), and PA frequency ≥ 3 times/week (*active*). Structural, compositional and relational features of PSNs were characterized using social network analysis. Using Partitioning Around Medoids, five distinct PSN phenotypes were identified. Group-specific predicted probabilities were derived by averaging regression model-based predictions within each phenotype; risk differences (RD) were then calculated as contrasts between these averaged risks.

Results: Cluster#1 (reference) had high proportions of healthy-diet (60%) and active (59%) *alters*, strong encouragement (71% diet, 77% PA), and moderate co-engagement in PA (52%). Cluster#5 showed moderate

B. MOTIVATION AND BEHAVIOR CHANGE

proportions of healthy-diet (43%) and active (27%) alters, moderate encouragement (54% diet, 69% PA), and frequent co-engagement (65% diet, 47% PA). Cluster#3 showed moderate proportions of healthy-diet (33%) and active (40%) alters, and moderate encouragement (49% diet, 64% PA). Cluster#2 had fewer healthy-diet (28%) or active (25%) alters and lower encouragement (29% diet, 43% PA). Cluster#4 had low proportions of healthy-diet (14%) or active (20%) alters, and low encouragement (37% diet, 29% PA). Across clusters, the proportion of active egos ranged from 24%-81%, and those with healthy diets from 47%-95%. Compared with Cluster#1, egos in all other PSN phenotypes showed higher risk of inactivity, greatest in #4 (RD= -0.64, SE= 0.14), followed by #5 (-0.58, SE= 0.14), #2 (-0.55, SE= 0.14), and #3 (-0.33, SE= 0.15). Clusters#4 and #5 also showed higher risk of unhealthy diets (RD= -0.48, SE= 0.14; RD= -0.30, SE= 0.13).

Conclusion: The varied nature of PSNs among young adults reflects diverse social contexts that may differentially influence cardiometabolic health, suggesting the potential of PSN-informed approaches to guide targeted interventions aimed at young adults.

I-P-B.26

Operationally Ready: The Association between Motivation, Psychological Needs and Health Behaviours in Military Personnel

M. Warmer^{1,2}, M. Western^{1,2}, J. Bilzon¹, J. Fallowfield³

¹University of Bath, Department for Health, Bath, United Kingdom, ²Centre for Motivation and Behaviour Change, Department for Health, Bath, United Kingdom, ³Royal Navy People Support (Musculoskeletal Injury Mitigation and Nutrition), Portsmouth, United Kingdom

Purpose: Musculoskeletal injuries (MSKI) are a leading cause of medical downgrades and reduced operational effectiveness in the UK Armed Forces. Initial military training presents a high-risk period for sustaining MSKI but also provides an important opportunity for promoting positive health behaviours to mitigate future MSKI risk. Self-Determination Theory (SDT) proposes that environments supporting the basic psychological needs for autonomy, competence, and relatedness foster autonomous motivation that maintains health behaviours. However, SDT remains underexplored within military contexts characterised by hierarchical structures. This study explored basic psychological need satisfaction and frustration, behavioural regulation and health behaviours in the Royal Navy.

Methods: A cross-sectional survey was conducted with 1,591 Royal Navy participants (15.6% female; aged 16–61 years), comprising 941 recruits, 190 Officer Cadets, and 460 trained personnel. Participants completed the Work Behaviour Regulation Questionnaire and the Basic Psychological Need Satisfaction and Frustration Scale. Health behaviours were assessed using the Defence Health Behaviour Index (assessing sleep quantity and quality, diet quality relative to fruit and vegetable intakes, hydration, physical activity, alcohol consumption and nicotine use). Weight-related health risk was determined from body weight, height and waist circumference. Linear regression and multivariate analysis of covariance (MANCOVA) were used to explore relationships and group differences.

Results: Supporting basic psychological needs in the workplace was positively associated with autonomous motivation ($P<0.002$), which was also associated with more favourable health behaviours ($\beta=0.119$, $P<0.001$). Frustrating psychological needs were associated with controlled motivation ($P<0.001$) and poorer health behaviours ($\beta=0.082$, $P=0.006$). Trained personnel reported higher weight-related ill-health risk, poorer health behaviours and greater psychological need frustration than trainees ($P<0.001$). Recruit trainees had the highest psychological need satisfaction, but also the greatest introjected and external motivation regulations (i.e., controlled by internal pressures or external rewards). Female and trained personnel exhibited greater weight-related ill-health risk ($OR=0.51$, $P<0.001$).

Conclusion: Creating need-supportive military environments may play an important role in fostering autonomous motivation and encouraging positive and sustained health behaviours. Efforts to ensure early-career phases develop self-determined motivation for their health behaviours could help mitigate MSKI risk and support a thriving military workforce.

I-P-B.27

Perceptions of Physical Activity after Patent Foramen Ovale (PFO)-associated Stroke and Percutaneous Device Closure: A Qualitative Study

J. Vallance¹, L. Corcoran¹

¹Athabasca University, Faculty of Health Disciplines, Athabasca, Canada

B. MOTIVATION AND BEHAVIOR CHANGE

Purpose: Paradoxical embolism through a patent foramen ovale (PFO) may be responsible for 5% of all ischemic strokes, and 10% of strokes in younger patients. After PFO-associated stroke, the PFO is closed using an occluder delivered via transcatheter procedure to block the opening between the left and right atria of the heart. Given the implication of the heart in PFO-associated stroke, there may be unique factors that may prevent returning to physical activity. The purpose of this study was to elicit patient perceptions of physical activity after PFO-associated stroke and transcatheter closure.

Methods: A purposive sample of 48 individuals who had a PFO-associated stroke participated in this study. Data were collected using semi-structured interviews from October 2024 to December 2024. Interviews of up to 60 minutes in length were conducted and recorded using the Zoom platform. The interviewer (JV) kept field notes consisting of initial impressions of the interview content and other relevant observations. Data were analyzed using Braun and Clarke's thematic analysis methodology. NVivo software was used to manage data, code, and generate themes.

Results: Participants were on average 47.7 years of age (SD=8.9). The mean age at the time of stroke was 44.7 (8.2), and average months since stroke was 38.5 (36.7) months. All participants were diagnosed with ischemic stroke or trans ischemic attack and all but 4 received subsequent PFO closure via transcatheter closure. The main themes (and sub themes) related to perceptions of physical activity after stroke and closure were: (1) psychological barriers (fear and anxiety, and closure device apprehension); (2) variability in fitness performance (subjective fitness improvement, and decline in physical activity); and (3) variability in physical recovery (lingering fatigue/neuro-fatigue, residual physical symptoms, and cardiac irregularities post-closure).

Conclusion: Participants reported several unique barriers (e.g., cardiac irregularities) to engaging in physical activity after stroke and closure. Participants reported anxiety about having another stroke, poorer fitness and function, and significant apprehension about being physically active with a new device in their heart. This study is the first step in understanding patient-centered issues around physical activity after PFO-associated stroke and after corrective closure.

I-P-B.28

Psychosocial Predictors of Adherence to a Structured Physical Activity Program in Pre- and Post-menopausal Women

M. Ha¹, A. Min¹, A. Kirkham¹, J. Gillen¹, K. Arbor-Nicitopoulos¹, L. Trinh¹

¹University of Toronto, Faculty of Kinesiology and Physical Education, Toronto, Canada

Purpose: Maintaining physical activity (PA) remains challenging for adult women despite health benefits. Guided by the Multi-Process Action Control (M-PAC) framework, the primary purpose of this study was to examine psychological predictors of adherence to independently completed moderate-to-vigorous physical activity (MVPA) during a 12-week structured PA intervention (goal of 150 min of MVPA/week) in pre- and post-menopausal women.

Methods: This is a secondary analysis of a larger, three-arm, randomized controlled trial (NCT06345937), pooling participants assigned to the two PA-receiving arms. Inactive women (i.e., <30min/week of MVPA) were recruited from the Greater Toronto Area. The intervention included two weekly supervised 30-minute MVPA sessions (one in-person, one virtual; >40% heart rate reserve [HRR]). Independent MVPA goals reached 90 minutes by Weeks 4-12. Adherence was defined as meeting the weekly 90 min/week MVPA goal measured by Garmin Venu wearable using an individualized threshold for each participant (>40% HRR). Baseline questionnaires included M-PAC constructs for reflective (instrumental/affective attitudes, perceived opportunity/capability), regulatory (goal-setting, planning), and reflexive processes (habit, identity). Hierarchical linear regression models were conducted, controlling for age, body mass index (BMI), and menopausal status.

Results: Forty-eight women ($M_{age}=49.6 \pm 12.1$ years; $M_{BMI}=30.5 \pm 4.4$ kg/m²; 41.7% White; pre-menopause n=29; post-menopause n=19) were included. The final model $F(6,41)=4.68$, $p=0.001$, $R^2=0.41$, demonstrated that reflective ($\beta=-29.31$, $p<0.001$) and reflexive ($\beta=17.63$, $p=0.035$) processes were significant predictors of adherence. Higher scores on reflective processes (more positive attitudes/judgements) were predictive of lower MVPA minutes whereas higher scores on reflexive processes (stronger habit and identity) were predictive of higher MVPA minutes. Regulatory processes were not significant predictors of adherence ($p=0.72$).

Conclusion: Aligned with the M-PAC framework, reflexive processes were key processes for MVPA adherence in women. On the other hand, reflective processes resulted in lower MVPA minutes likely due to previously inactive females potentially having positive outcome expectations for MVPA, but were unaware of potential barriers that may arise. Findings highlight the importance of building PA habits and identities to support PA maintenance in women.

B. MOTIVATION AND BEHAVIOR CHANGE

I-P-B.29

Early-pregnancy Nutritional Intervention Targeting Diet Quality and Glucose Homeostasis in Individuals at Risk for Gestational Diabetes: Primary Results from a Randomized Controlled Trial

E. Bernier^{1,2,3}, A.-S. Plante^{2,3}, S.-M. Abran^{2,3}, S. Harrison^{1,3}, P. Lemieux^{2,4}, J. Robitaille^{1,2,3}, S. Lemieux^{1,3}, S. Desroches^{1,3}, A. Bélanger-Gravel^{3,5}, S. Maheux-Lacroix^{2,4}, S.J. Weisnagel^{2,4}, S. Demers⁴, F. Camirand Lemyre^{6,7}, M. Boulet⁸, J.-P. Baillargeon^{7,9}, A.-S. Morisset^{1,2,3}

¹Université Laval, École de Nutrition, Québec, Canada, ²Centre de Recherche du CHU de Québec-Université Laval, Québec, Canada, ³Université Laval, Centre Nutrition, Santé et Société (NUTRISS), Institut sur la Nutrition et les Aliments Fonctionnels (INAF), Québec, Canada, ⁴Université Laval, Faculté de Médecine, Québec, Canada, ⁵Université Laval, Département d'Information et de Communication, Québec, Canada, ⁶Université de Sherbrooke, Département de Mathématiques, Sherbrooke, Canada, ⁷Centre de Recherche du CHU de Sherbrooke, Sherbrooke, Canada, ⁸Centre Intégré Universitaire de Santé et de Service Sociaux de l'Estrie-CHU de Sherbrooke, Sherbrooke, Canada, ⁹Université de Sherbrooke, Département de Médecine, Sherbrooke, Canada

Purpose:

According to Diabetes Canada latest guidelines, effective and acceptable interventions are needed to improve glucose homeostasis and support pregnant individuals at risk for GDM. This randomized control trial (RCT) aims to assess the effects of an early-pregnancy nutritional intervention on glucose homeostasis of individuals at risk for GDM, compared to usual care.

Methods: Design: Single-center, two-arm, parallel-group RCT. Study population: Pregnant adults, ≤ 14 weeks' gestation with a singleton pregnancy, ≥ 1 risk factor for GDM according to Diabetes Canada Guidelines. Intervention: Early-pregnancy nutritional intervention promoting healthy eating based on Canada's Food Guide, emphasizing motivation and self-efficacy, including: 4 individualized counselling sessions with a dietitian using motivational interviewing (12, 18, 24, and 30 weeks); 10 educational video clips on healthy eating during pregnancy; and a virtual support community moderated by a dietitian publishing weekly posts on healthy eating during pregnancy addressing all dimensions of social support. Control: Usual care (does not include nutrition counselling). Data collection: 3 on-site visits (10-14, 24-28, and 32-36 weeks) including 2-h 75g oral glucose tolerance tests and questionnaires. Primary outcome: Between-group difference in mean change in fasting plasma glucose (FPG) from 1st to 3rd visit. Primary analysis: Two-sample one-sided t-test.

Results: Of 150 randomized participants, 125 (63 intervention, 62 control) with complete primary outcome data were included in this analysis. Baseline variables were similar between groups (31.9 $\pm$ 4.1 vs 32.8 $\pm$ 4.5 years old; 29.5 $\pm$ 7.9 vs 29.1 $\pm$ 6.3 kg/m²; 1.6 $\pm$ 0.8 vs 1.5 $\pm$ 0.7 GDM risk factors, $p > 0.05$), except for baseline FPG which was lower in the intervention group (4.5 $\pm$ 0.3 vs 4.7 $\pm$ 0.4 mmol/L, $p < 0.05$). Change in FPG from 1st to 3rd visits did not differ between groups, even after adjusting for baseline FPG (-0.1 $\pm$ 0.3 vs -0.1 $\pm$ 0.4 mmol/L, $p > 0.05$). Higher baseline FPG predicted greater FPG reduction, independent of group ($\beta = -0.47$, $p < 0.0001$).

Conclusion: No significant effect of the intervention was observed on the primary outcome. Further exploratory analyses on other glucose homeostasis markers will be conducted.

I-P-B.30

Lifestyle Behaviors Contribute to the Expression of Genetic Susceptibility to Obesity: Results from the Quebec CARTaGENE Cohort

L. Pérusse^{1,2}, R. Jacob³, A. Tremblay^{1,2}, V. Drapeau^{1,2}, J.-P. Drouin-Chartier^{4,2}

¹Université Laval, Kinesiology, Quebec City, Canada, ²NUTRISS Research Center / Institute on Nutrition and Functional Foods (INAF), Quebec City, Canada, ³University of Guelph, Department of Family Relations and Applied Nutrition, Guelph, Canada, ⁴Université Laval, Faculty of Pharmacy, Quebec City, Canada

Purpose: Mediation analysis can be used to understand how an exposure leads to an outcome but has rarely been used to identify lifestyle mediators of the genetic risk of obesity. We hypothesize that healthy lifestyle behaviors partly explain genetic predisposition to obesity. The objective is to investigate the role of lifestyle behaviors in mediating genetic predisposition to obesity.

B. MOTIVATION AND BEHAVIOR CHANGE

Methods: The study included 20,208 adult participants from the Quebec CARTaGENE biobank. Dietary intake was assessed using a validated FFQ and the International Physical Activity Questionnaire (IPAQ) was used to assess physical activity (PA). Information on smoking and sleeping habits were obtained by questionnaire. A healthy lifestyle score (HLS) based on the adherence to five healthy behaviors was computed: 1) not smoking; 2) being physically active (≥ 150 min/week of moderate to vigorous PA); 3) eating a healthy diet (Alternate Healthy Eating Index $\geq 50\%$); 4) light to moderate alcohol consumption (1-30 g/day for men; 1-15 g/day for women) and 5) getting enough sleep (7-8 hrs/day). Causal mediation analysis was used to investigate the mediating effects of lifestyle behaviors on the relationship between genetic risk of obesity, assessed using a polygenic risk score (PRS), and BMI and percent body fat (FAT) assessed by bioimpedance. All analyses were performed on age- and sex-adjusted data.

Results: The proportion of participants with a healthy lifestyle (HLS $\geq 4/5$) was 36% among men and 39% among women. The PRS was significantly ($p < 0.0001$) associated with BMI ($R^2 = 14.0\%$) and FAT ($R^2 = 6.6\%$). The HLS was inversely associated with BMI and FAT and the association between the PRS and obesity outcomes was partly explained by the HLS for BMI ($\beta_{\text{indirect}} = 0.052 \pm 0.015$; percent mediation 1.74%) and for FAT ($\beta_{\text{indirect}} = 0.094 \pm 0.025$; 2.67%). Being physically active and getting enough sleep were the two lifestyle behaviors driving this mediating effect.

Conclusion: Healthy lifestyle behaviors, particularly being physically active and having adequate sleep, partly explain genetic susceptibility to obesity. In a precision lifestyle medicine framework, targeting these behaviors may be helpful to manage obesity in individuals with a genetic predisposition to obesity.

I-P-B.31

How Personality Traits Influence Response to a 5-month Digital Physical Activity Intervention

L. Hatzinger¹, M. Samuelson¹, J. Morales¹, M. Hewus¹, W.-L. Wang¹, T. Mason¹, J. Huh¹, D. Van Dyck², G. Dunton^{1,3}

¹University of Southern California, Population and Public Health Sciences, Los Angeles, United States, ²Ghent University, Movement and Sports Sciences, Ghent, Belgium, ³University of Southern California, Psychology, Los Angeles, United States

Purpose: Lack of physical activity (PA) is a public health problem. Although observational studies demonstrate associations between personality and PA, understanding the influence of personality on PA change across an intervention may provide novel insights into personality-tailored interventions. The current study examined how personality and sensation-seeking traits influenced change in monitor-based PA during a 5-month digital therapeutic crossover intervention among inactive adults with overweight/obesity.

Methods: Participants (N=212; 19-85-years, 63% female) received 16 weeks of heart-rate and affect-based PA goals, with a two-week washout between conditions. Personality (e.g., extraversion, agreeableness) and sensation-seeking (e.g., disinhibition, experience-seeking) traits were reported at baseline using the Ten-Item Personality Inventory and Brief Sensation Seeking Scale, respectively. PA was measured continuously by a Fitbit Versa 3 smartwatch. Multivariable multilevel linear models examined the effects of personality and sensation-seeking traits on within-person changes in weekly PA across time, controlling for time-invariant (i.e., age, gender, condition order) and time-varying (i.e., intervention condition) covariates. All subscales were grand-mean-centered.

Results: Higher boredom susceptibility (Linear: $p = .03$, Quadratic: $p = .02$) and lower disinhibition (Linear: $p = .01$, Quadratic: $p = .01$) were associated with a steep decrease, followed by a slight increase in moderate PA starting at 11 weeks. Participants with higher conscientiousness (Linear: $p < .001$, Quadratic: $p < .001$) and lower emotional stability (Linear: $p = .05$, Quadratic: $p = .02$) showed a steep decrease in moderate PA, followed by a slight increase starting at 11 weeks. Greater disinhibition (Linear: $p = .02$, Quadratic: $p = .01$) and lower conscientiousness (Linear: $p < .001$, Quadratic: $p < .001$) were associated with a steep increase, followed by a slight decrease in light PA starting at 10 and 8 weeks, respectively. There were no significant effects of condition order or intervention condition, nor the sedentary time outcome.

Conclusion: More impulsive individuals showed immediate positive changes in light PA, whereas those more calm, disciplined, or prone to boredom showed negative changes in moderate PA with delayed increases. The results could support efforts for developing personalized interventions based on personality traits (e.g., tailored content). Future studies should examine how personality influences engagement, adherence, and compliance to further inform personalized PA interventions.

B. MOTIVATION AND BEHAVIOR CHANGE

I-P-B.33

Reallocating Time across Sleep, Sedentary Behaviour, and Physical Activity is Associated with Composite Sleep Health in Shift-workers

G. Passfield¹, T. Stewart¹, C. Crofts¹

¹Auckland University of Technology, Human Potential Research Institute, Auckland, New Zealand

Purpose: Shift workers experience disrupted sleep and constrained opportunities for physical activity, yet how 24-hour time-use trade-offs relate to multidimensional sleep health in this population is poorly understood. This study examined associations between 24-hour time use and composite sleep health (CSH) in shift workers using compositional data analysis, extending integrative behavioural modelling to a high-risk occupational group.

Methods: Shift workers from a major South Pacific airline completed 7 days of continuous monitoring using thigh-worn and low-back-worn accelerometers. Daily time use was summarised as a four-part 24-hour composition (sleep, sedentary time, light physical activity [LPA], and moderate-to-vigorous physical activity [MVPA]) averaged across valid days. CSH was operationalised as a week-level score (0–10) derived from five accelerometer-based sleep dimensions: duration, variability, efficiency, timing, and regularity. Associations between the time-use composition and CSH were examined using isometric log-ratio-transformed compositional regression models adjusted for age, sex, BMI, and wear time. Compositional isotemporal substitution models estimated predicted differences in CSH for 60-minute reallocations (in 15-minute increments) between behaviours.

Results: The analytic sample included 101 shift workers (mean age 41.0 years; 63% women) contributing a mean of 6.7 valid monitoring days, with a mean CSH score of 2.9/10. The average daily composition comprised 864 minutes sedentary time, 82 minutes LPA, 81 minutes MVPA, and 414 minutes sleep. Greater relative sedentary time was associated with lower CSH ($B = -5.7$, $p < 0.001$), while greater relative sleep was associated with higher CSH ($B = 6.6$, $p < 0.001$). Associations with LPA and MVPA were weaker. Reallocating 60 minutes away from sedentary time was associated with higher predicted CSH ($\Delta = +0.85$; 95% CI 0.43 to 1.26), whereas reallocating 60 minutes away from sleep was associated with lower predicted CSH ($\Delta = -1.22$; 95% CI -1.84 to -0.60).

Conclusion: Applying 24-hour compositional modelling to shift workers demonstrates how constrained behavioural trade-offs relate to multidimensional sleep health and translates complex associations into interpretable reallocations. These findings highlight sedentary time and sleep as key behavioural targets and support further integration of behavioural timing, context, and roster characteristics in shift-work health research.

I-P-B.34

Correlates of Physical Activity, Sedentary Behavior and Sleep in Adults with Type 1 Diabetes Mellitus

L. Bogaert^{1,2}, P. Calders¹, E. Dirinck³, B. Lapauw⁴, V. Verbestel^{5,6}, I. Willems^{1,7}, M. De Craemer¹

¹Ghent University, Rehabilitation Sciences, Ghent, Belgium, ²Research Foundation Flanders, Brussels, Belgium, ³Antwerp University Hospital, Endocrinology, Antwerp, Belgium, ⁴Ghent University Hospital, Endocrinology, Ghent, Belgium, ⁵Maastricht University, Health Promotion, Research Institute of Nutrition and Translational Research in Metabolism (NUTRIM), Maastricht, Netherlands, ⁶Maastricht University, Department of Health Promotion, Care and Public Health Research Institute (CAPHRI), Maastricht, Netherlands, ⁷Brussels University, Brussels, Belgium

Purpose: Adopting a healthy lifestyle that includes sufficient physical activity (PA), limited sedentary behavior (SB), and adequate sleep, collectively referred to as 24-hour movement behaviors (24h-MBs), is an essential component of type 1 diabetes (T1D) management. However, many adults with T1D struggle to achieve and maintain optimal levels of PA, SB and sleep. To effectively promote healthy 24h-MBs in this population, a better understanding of the correlates of these behaviors is needed.

Methods: The 24h-MBs were objectively measured using an ActiGraph GT3X+ accelerometer worn for fourteen consecutive days. Potential correlates were assessed using a reliable self-reported questionnaire, capturing correlates across three levels of the SEM: intrapersonal (5 constructs e.g. attitude), interpersonal (two constructs e.g. social support), and environmental (one construct e.g. neighborhood). The association between the correlates and each individual behavior (total PA, SB and sleep in minutes) was investigated via the Confidence Interval-Based Estimation of Relevance method. This method identifies the most relevant correlates to include in intervention development by evaluating both the room for improvement of each correlate (mean, 99.9% CI) and their strength of correlation (r , 95% CI) with the behaviours of interest.

B. MOTIVATION AND BEHAVIOR CHANGE

Results: Data of sixty adults with T1DM (mean age 43.9 years; 50% male) were analyzed. Participants generally reported a positive attitude and a high autonomous motivation toward PA, both of which were positively correlated with total PA levels. Social modeling, such as having a physically active partner or colleague, was correlated with higher PA levels, as did living in a green and safe neighborhood. Participants also reported a generally positive attitude toward interrupting SB, which was correlated with lower SB. However, self-efficacy to interrupt SB was rated low to moderate, indicating potential for improvement. Autonomous motivation also emerged as a relevant correlate of sleep duration, showing both room for improvement and a significant positive association.

Conclusion: These results provide insight into the determinants that should be targeted in the development of interventions aimed at promoting healthier 24h-MBs in adults with T1DM. The results emphasize the importance of targeting correlates across intrapersonal, interpersonal, and environmental level, highlighting the multilevel and complex nature behavior change.

I-P-B.35

Is There an Association between 24-Hour Movement Behaviors and Glycemic Control in Adults with Type 1 Diabetes?

L. Bogaert^{1,2}, E. Dirinck^{3,4}, B. Lapauw^{5,6}, P. Calders¹, D. Dumuid⁷, A. Miatke⁷, M. De Craemer¹

¹Ghent University, Rehabilitation Sciences, Ghent, Belgium, ²Research Foundation Flanders, Brussels, Belgium, ³Antwerp University Hospital, Endocrinology, Antwerp, Belgium, ⁴University of Antwerp, Antwerp, Belgium, ⁵Ghent University Hospital, Endocrinology, Ghent, Belgium, ⁶Ghent University, Department of Internal Medicine and Pediatrics, Ghent, Belgium, ⁷Adelaide University, Alliance for Research in Exercise, Nutrition and Activity, Allied Health & Human Performance, Adelaide, Australia

Purpose: Maintaining glucose levels within the target range of 70-180 mg/dl (time in range; TIR) is key in the management of type 1 diabetes mellitus (T1DM) to prevent long-term complications. A healthy lifestyle, characterized by sufficient physical activity (PA), adequate sleep, and limited sedentary behavior (SB), collectively referred to as 24-hour movement behaviors (24h-MBs), may play an important role in achieving optimal glycemic control. This study investigates the association between the composition of 24h-MB composition and TIR in adults with T1DM.

Methods: Over a 14-day monitoring period, 24h-MBs were assessed using ActiGraph GT3X+ accelerometers, and glucose levels were measured using continuous glucose monitors. Compositional data analysis was used to construct daily compositions of 24h-MBs (sleep, SB, light PA (LPA) and moderate-to-vigorous PA (MVPA)) and daily composition of time spent in different glucose ranges (time below range, TIR and time above range). Multilevel models were used to examine associations between 24h-MBs and TIR at both the between-person and within-person level. Time reallocation models were conducted when significant associations were identified.

Results: Sixty-three adults with T1DM (mean age 44±12.3 years; 49% male) were included. At the between-person level, a significant negative association was observed between TIR and MVPA, relative to the remaining behaviors (p=0.02). Proportional reallocation of 30 minutes from the other behaviors to MVPA was associated with a decrease of 20 min/day in TIR. At the within-person level, a significant positive association was found between TIR and LPA (p=0.001). Proportional reallocation of 30 minutes to LPA was associated with an increase of TIR of 10 min/day.

Conclusion: These findings highlight the importance of a balanced 24h-MB profile in adults with T1DM. Greater time spent in MVPA was associated with lower TIR, potentially due to exercise-related insulin adjustments, increased carbohydrate intake, and physiological responses such as adrenaline-induced hyperglycemia. In contrast, at the day-to-day within-person level, spending more time in LPA was associated with greater time in range. Although the effects are small, these results suggest that promoting LPA may be beneficial strategies for improving daily glycemic control in this population.

Feasibility, Acceptability and Preliminary Impact on Diet Quality of the Healthy Weight for Life™ Program Combined with Medical Nutrition Therapy; A Randomised Controlled Pilot Study

H. Donnelly^{1,2}, E. Clarke^{1,2}, G. Britton³, N. Hedditch³, R. Gallagher^{3,1}, C. Collins^{1,2}

¹The University of Newcastle, School of Health Sciences, Newcastle, Australia, ²Hunter Medical Research Institute,

B. MOTIVATION AND BEHAVIOR CHANGE

Nutrition and Metabolic Health Program, New Lambton Heights, Australia, ³Honeysuckle Health Pty Ltd, Newcastle, Australia

Purpose: Poor diet quality has been associated with greater risk of developing overweight and obesity, type 2 diabetes, cardiovascular disease, and osteoarthritis. Weight management is recommended in guidelines for these conditions. The impact of current weight management interventions, including the Healthy Weight for Life™ (HWFL) program that uses meal replacements, on diet quality has not been assessed. Further, the role of a dietitian providing medical nutrition therapy (MNT) combined with the HWFL program has not been evaluated. MNT is an evidence-based approach where dietary interventions are tailored to the individual's needs, medical history, lifestyle, and dietary preferences. Therefore, the primary aim of this pilot study is to evaluate feasibility, acceptability and preliminary impact of adding personalised MNT consultations to the HWFL program on diet quality. Secondary outcomes include weight and osteoarthritis scores.

Methods: An 18-week randomised controlled pilot trial was undertaken, with eligible HWFL program participants randomised to either usual care arm (HWFL program) or HWFL with MNT. A validated food frequency questionnaire assessed diet quality (% energy from nutrient-dense core food) and provided intervention participants with personalised feedback on food and nutrient adequacy. Weight and knee osteoarthritis outcomes using the hip and knee osteoarthritis outcome scores, were self-reported and used to assess outcomes. Project acceptability was assessed by process evaluation questionnaire. An intention-to-treat analysis was undertaken using generalised linear mixed models with post-estimations reported as mean (95% CI).

Results: Forty participants (75% female, 62±10years, 78% osteoarthritis) enrolled in the study. Baseline diet quality was poor (34% energy from non-core foods). Post-intervention both intervention and usual care groups significantly improved their diet quality and reduced weight, but there were no significant differences between groups. Sub-scores for knee osteoarthritis function significantly improved in the intervention compared to the control group (mean between group difference 17.4, 95%CI 1.6, 33.1), though after correcting for multiple testing this was no longer significant. Overall intervention acceptability was high.

Conclusion: Both intervention and usual care arms demonstrated significant improvements in diet quality. All intervention participants found MNT was a highly acceptable addition to HWFL. Significant improvements in knee osteoarthritis function were reported in the intervention group.

I-P-B.37

Parent Weight-loss Methods and Parent-child Communication about Weight, Eating, and Physical Activity Behaviors

T. Dregney¹, K. Hendel², A. Johnson²

¹University of Minnesota, Cancer Health Disparities T32 Training Program, Minneapolis, United States, ²University of Minnesota, Division of Epidemiology and Community Health, Minneapolis, United States

Purpose: Parent-child conversations about weight and health behaviors can shape children's attitudes toward eating, physical activity, and body image. Weight-focused conversations, often referred to as "weight talk," are linked to greater risk for disordered eating, whereas discussions emphasizing healthy eating and regular physical activity, are associated with more positive outcomes. The use of glucagon-like peptide-1 receptor agonists (GLP-1RAs) for weight loss has increased rapidly among adults. However, little is known about how a parent's own weight-loss efforts, and specifically the method used, relate to the frequency and type of parent-child conversation about weight and health behaviors.

Methods: We recruited a convenience sample of parents at a Midwestern state fair (n = 118). Eligible parents had attempted structured weight loss (excluding surgery) within the past 18 months and lived with a child aged 2-18 years. Parents were grouped by weight-loss method (GLP-1RA use vs. no GLP-1RA use). Six items adapted from Project EAT assessed frequency of weight-related and health behavior conversations (e.g., discussing one's own weight, shape, or size; discussing physical activity without mentioning weight). Responses were measured on a 5-point Likert scale (never to always). Linear regression models compared conversation frequency between groups, adjusting for parent age and gender.

Results: Parents were predominantly female (70%) and White (79%), with a mean age of 42 ± 7 years; 17% reported GLP-1RA use. GLP-1RA users and non-users were similar in BMI (33.7 vs. 31.2 kg/m²) and number of recent weight-loss attempts (2.6 vs. 2.5). GLP-1RA users reported less frequent discussion of physical activity without mentioning weight compared to non-users (p = .03). No differences between groups were observed across the other conversation items.

Conclusion: These preliminary findings suggest little difference in the frequency of parent-child conversations about weight or eating behaviors based on parental weight loss method, but parents using GLP1RA may discuss physical

B. MOTIVATION AND BEHAVIOR CHANGE

activity without mentioning weight less than parents trying to lose weight via other methods. Adequately powered, longitudinal studies are needed to clarify differences observed between GLP1RA users and non-users in physical activity conversations and the potential implications for child health and body image.

I-P-B.38

Understanding Physical Activity Promotion in Primary Care: Perspectives from Family Physicians

R. Nikolopoulos¹, A. Bélanger-Gravel², P. Nugus³, A. Gauthier⁴, T. Carver³, C. Filip⁵, T. Barnett¹

¹McGill University, Department of Family Medicine, Montreal, Canada, ²Université Laval, Department of Information and Communication, Québec City, Canada, ³McGill University, Institute of Health Sciences Education, Montreal, Canada, ⁴St. Mary's University Family Medicine Group, Montreal, Canada, ⁵Jardins-Roussillon University Family Medicine Group, Châteauguay, Canada

Purpose: We aimed to identify the behavioural influences shaping family physicians' (FPs) physical activity (PA) promotion practices in primary care (PC).

Methods: This qualitative study included 11 FPs, comprising staff physicians and postgraduate year 2 family medicine residents, recruited from two University Family Medicine Groups in Québec, Canada. Semi-structured interviews were 30-60 minutes in duration and were conducted on-site or via videoconference. Interviews were recorded, transcribed verbatim, and analyzed in NVivo using a hybrid thematic analysis guided by the Theoretical Domains Framework, which was initially designed to examine factors shaping health professionals' delivery of health recommendations.

Results: Key individual, interpersonal and organizational factors influencing FPs' practice of PA counselling in PC were identified. Beliefs about capabilities and beliefs about consequences emerged as influential domains underlying physicians' motivation to engage in PA promotion. Motivation was affected by physicians' perceptions of limited past success with PA promotion interventions. It was also driven by lack of impetus to prioritize PA assessment and counselling in routine practice. Patient-related factors further informed FP motivation. These included the presence of contraindications to PA, patients' past or current engagement in or enjoyment of PA, and patient-initiated inquiries that align with the therapeutic benefits of PA. Environmental context and resources shaped physicians' opportunities to provide PA counselling through competing clinical priorities and time-limited appointments, and variability in patients' needs and access to PA opportunities. FPs were confident in their capability to engage in PA counselling, facilitated by their knowledge of the benefits of PA for disease prevention and management.

Conclusion: Findings suggest that promoting PA in PC requires addressing motivational determinants, namely FP beliefs about capabilities and consequences, while limiting opportunity constraints related to time pressures and competing priorities. Aligning incentives, reinforcing the clinical benefits of PA, and integrating PA assessment into routine workflows may support more consistent implementation despite individual and organizational contextual variability. This study provides a foundation for designing and piloting a PC intervention to promote PA that is tailored to the needs of both patients and physicians, supporting broader efforts to reduce the global burden of disease.

I-P-B.40

Action Planning and Behavioral Automaticity Serially Mediate the Association between Trait Self-Control and Physical Activity: A Prospective Cohort Study

J. Rumpf¹, J. Koenigstorfer¹

¹Technical University of Munich, Chair of Sport and Health Management, Munich, Germany

Purpose: Emerging evidence indicates that behavioral automaticity (i.e., habit) mediates the association between trait self-control and physical activity (PA). However, the underlying mechanisms linking trait self-control to behavioral automaticity in PA remain poorly understood, and prior research has largely relied on small sample sizes and retrospective self-report measures of PA. Action planning represents a self-control strategy that facilitates automatic behavioral regulation and may enable individuals high in self-control to enact PA with greater automaticity, thereby supporting more frequent engagement. This study examined whether action planning and behavioral automaticity serially mediate the association between trait self-control and objectively assessed PA.

Methods: A preregistered, two-wave prospective cohort study was conducted in partnership with a corporate fitness platform operating in Germany and Austria. At baseline, participants ($N = 411$; 61.6% female; $M_{\text{age}} = 45.7 \pm 10.9$)

B. MOTIVATION AND BEHAVIOR CHANGE

completed an online survey assessing trait self-control (Brief Self-Control Scale), action planning (6-item scale: day, time, frequency, duration, place, mode), and behavioral automaticity (Self-Report Behavioral Automaticity Index). PA was operationalized as the number of fitness facility visits recorded during the subsequent month. Serial mediation analyses were conducted using PROCESS macro (version 5.0; SPSS), with action planning and behavioral automaticity specified as serial mediators and gender and body mass index included as covariates.

Results: Trait self-control was positively associated with PA (total effect: $\beta = 1.95$, $p < .001$, 95% CI [1.07, 2.83]). Serial mediation analyses indicated a significant indirect effect of trait self-control on PA through action planning and behavioral automaticity ($\beta = 0.07$, 95% CI [0.03, 0.14]). In addition, a significant indirect effect via behavioral automaticity emerged ($\beta = 0.60$, 95% CI [0.28, 0.97]). After accounting for the mediators, the direct effect of trait self-control on PA remained significant ($\beta = 1.13$, $p = .019$, 95% CI [0.19, 2.08]), indicating partial mediation (final model $R^2 = .094$).

Conclusion: Action planning appears to enable individuals high in self-control to enact PA with greater automaticity, thereby supporting more frequent engagement. PA interventions may incorporate action planning to promote habit formation, particularly among individuals low in self-control. Future research should test these pathways experimentally to elucidate causal relationships.

II-P-B.01

Substituting Baseline Moderate to Vigorous Physical Activity with Sleep, Sedentary Behavior or Light Physical Activity: Associations with Subsequent 12-month Exercise Motivation

A.L. Palmeira^{1,2}, S.C. Larsen³, J. Prieto⁴, T. Boto¹, M. Marques⁵, J. Encantado⁶, I. Santos^{7,8}, G. Horgan⁹, R.J. Stubbs¹⁰, B.L. Heitmann^{3,11}

¹Universidade Lusófona, CIDEFES, Lisboa, Portugal, ²Universidade do Porto, CIFI2D, Porto, Portugal, ³Bispebjerg and Frederiksberg Hospital, The Capital Region, Research Unit for Dietary Studies, The Parker Institute, Copenhagen, Denmark, ⁴Universidad Internacional de La Rioja, La Rioja, Spain, ⁵Escola Nacional de Saúde Pública NOVA, Comprehensive Health Research Centre (CHRC), Lisboa, Portugal, ⁶Universidade de Lisboa, Faculty of Human Kinetics, CIPER, Lisboa, Portugal, ⁷Universidade de Lisboa, Faculdade de Medicina, Laboratório de Nutrição, Lisboa, Portugal, ⁸Universidade de Lisboa, Faculdade de Medicina, Instituto de Saúde Ambiental, Lisboa, Portugal, ⁹Biomathematics & Statistics Scotland, Edinburgh, United Kingdom, ¹⁰School of Psychology, University of Leeds, Appetite Control and Energy Balance Group, Leeds, United Kingdom, ¹¹University of Copenhagen, Department of Public Health, Section for General Medicine, Copenhagen, Denmark

Purpose: „Every move counts“. While this message is mainly focused on evidence from physiology-based studies, little is known about the potential effects of different durations of the 24h movement components on subsequent motivational variables.

This study used isothermal substitution models to investigate the relationship between baseline moderate to vigorous physical activity (MVPA) and subsequent changes in exercise motivation, when MVPA is substituted with either sleep, sedentary behavior (SB), or light-physical activity (LPA).

Methods: Participants were 1,089 adults from the NoHoW trial, a weight loss maintenance intervention (BMI = 29.5 (5.2) kg/m², initial weight loss = 11.5 (6.5) kg). Sleep, SB, LPA and MVPA were objectively measured using Fitbit Charge 2 during 14-day periods at baseline. Exercise motivation was measured at baseline at 6 and 12 months using the BREQ, assessing Autonomous and Controlled Motivation (.79 < McDonald's Omega < .93). Isothermal substitution models were used to explore the association between baseline MVPA and subsequent changes in exercise motivation in which time used for MVPA was substituted with the same time from either sleep, SB, and LPA, while adjusting for potential confounding factors (e.g. sex, age, SES, previous weight loss, among others).

Results: Each block of 30 minutes more LPA at the expense of MVPA was associated with a decrease of -0.07 ([-0.13, -0.02] $p = .007$) in autonomous exercise motivation (AEM) at 6 months. A similar pattern of decreased AEM was observed when substituting MVPA by 30-minute blocks of SB with reductions of -0.08 ([-0.12, -0.03] $p = .001$) or in sleep with reductions of -0.08 ([-0.13, -0.03] $p = .003$). The 12-month change in AEM mirrored the 6-month changes. No significant associations were seen for changes in controlled exercise motivation.

Conclusion: Decreases in AEM were seen at 6 and 12 months when more LPA, SB, and Sleep replaced baseline MVPA. Therefore, the notion that “Every move counts”, even LPA, is linked to sustained AEM is not accurate. Results suggest that reducing MVPA can negatively affect motivation, creating a harmful cycle of decreased movement and AEM. However, we speculate that enhancing AEM may be possible by increasing MVPA, at the expense of other activities.

B. MOTIVATION AND BEHAVIOR CHANGE

II-P-B.02

The Development of a Physical Activity and Behaviour Profile

D. Stokman-Meiland^{1,2}, M. Berger^{3,4}, R van den Bosch⁴, M. Westerbeek-Couwenberg³, F. Allonsius³, R. Dekker^{2,3}, A. de Rooij^{3,5}

¹Basalt Rehabilitation Centre, Innovation, Quality + Research, Leiden, Netherlands, ²University of Groningen, University Medical Center Groningen (UMCG) Nethen, Department of Rehabilitation Medicine, Groningen, Netherlands, ³Basalt Rehabilitation Centre, Innovation, Quality + Research, The Hague, Netherlands, ⁴The Hague University of Applied Sciences (THUAS), Center of Expertise in Health Innovation, The Hague, Netherlands, ⁵Leiden University Medical Center (LUMC), Department of Orthopaedics, Rehabilitation and Physical Therapy, Leiden, Netherlands

Purpose: Physical activity is of particular importance in stroke patients for physical and mental recovery. However, guidelines regarding healthy physical behaviour (i.e. physical activity and sedentary behaviour) are often unmet. More insight in the physical behaviour and barriers to that behaviour of an individual stroke patient could support the patient and healthcare professional (HP) in goal setting aimed at healthy physical behaviour. Therefore, the aim of this study was to develop a 'physical activity and behaviour profile' and to test this profile in clinical practice.

Methods: Mixed methods were used. Physical behaviour was measured with an Actigraph during one week and barriers to physical activity were measured with the Determinants of Physical Activity Questionnaire (DPAQ). Both outcomes were visualized in a 'physical activity and behaviour profile'. Focus groups with 6 stroke patients and 8 HPs were conducted to determine the needs and preferences of end-users regarding the content, design and functionality of the profile. Finally, the usability, applicability and feasibility of the profile was tested in a field test with 30 stroke patients and their HPs.

Results: Consensus was reached regarding a specified target behaviour consistent with the Dutch physical activity guidelines. Also, consensus was reached regarding the content, design and functionality of a 'physical activity and behaviour profile'. Preliminary results of testing the profiles in clinical practice showed that the profiles were found useful for discussing the physical behaviour and barriers to physical activity of the individual stroke patients, and as an aid for personalized goal setting. Occupational therapists, physical therapists and movement therapists found the profile applicable to their discipline and to stroke patients. Feasibility was considered sufficient in this study.

Conclusion: A 'physical activity and behaviour profile' measuring physical behaviour and barriers to physical activity, was developed in co-creation with stroke patients and healthcare professionals. The usability, applicability and feasibility of this profile in clinical practice seems promising.

II-P-B.03

Mixed-methods Exploration of the Role of Teacher Motivation and Habit Formation in Delivering Daily Physical Activity 12 Months Into a State-wide School Physical Activity Program

W. Pascoe^{1,2,3}, C. Lane^{1,2,3}, A. Hall^{1,2,3}, E. Riley-Gibson^{1,2,3}, A. Shoesmith², N. Nathan^{1,2,3}

¹University of Newcastle, Newcastle, Australia, ²NSW Health, Newcastle, Australia, ³National Centre of Implementation Science, Newcastle, Australia

Purpose: Resources and population health improvements are forfeited each year as physical activity initiatives fail to sustain. Behaviour change theories highlight the pivotal role of motivation in behaviour. However, research often overlooks the influence of implementer motivation in health initiative sustainment. Teachers commonly report being motivated by a desire to help students and personal career progression, yet it is unclear whether these motivating factors extend to the implementation of physical activity initiatives. Further, evidence on teachers' automatic motivation and habit use for sustainment is limited.

The primary aim of the study was to explore teachers' perceived motivation and how motivation and habits impact the delivery of classroom physical activity 12 months into a state-wide sustainment trial.

Methods: Complementary embedded sequential mixed-methods (QUAL->quant) research design was used to address the research aims. Interviews and surveys were collected and analysed concurrently, then assessed sequentially. Teachers completed 30-minute interviews on their motivation to schedule Energisers and automatic-motivation processes, such as habits. Teachers also completed surveys assessing the perceived influence of pre-identified evidence-based determinants to sustainment. Quantitative survey items relevant to the qualitative results were

B. MOTIVATION AND BEHAVIOR CHANGE

identified and integrated using meta-inference to form the results.

Results: The results suggest that planned and unplanned habits are being utilised to sustain the delivery of the physical activity program. Three key themes were identified: (1) High motivation to deliver Energisers, (2) Energisers are a team sport, and (3) Implementation intentions and naturally occurring cues. All four stages of habit development were described in the interviews. Further subthemes were identified and explained. Recurring topics of discussion include the benefits of routine, whole-school buy-in, and cues. Quantitative results supported all the themes identified, highlighting specific influential factors within the themes, such as executive leadership.

Conclusion: Whilst evidence-based studies highlight the importance of motivation in personal health behaviours and clinical settings, the role of implementer motivation and habit formation in sustaining physical activity initiatives in community settings remains understudied. Findings suggest that, whilst teachers describe a strong reflective desire to sustain the initiative, automatic motivation and habitual behaviours could be a less burdensome method to sustain the delivery of school physical activity initiatives.

II-P-B.04

Life after a Combined Lifestyle Intervention. Do Participants Maintain Behavior Changes?

F. Meester¹, B. Dorhout¹, D.-J. Barten¹, D. Bossen², K. Braam³, A. Ronteltap¹

¹HU University of Applied Sciences Utrecht, Utrecht, Netherlands, ²Amsterdam University of Applied Sciences, Amsterdam, Netherlands, ³Inholland University of Applied Sciences, Haarlem, Netherlands

Purpose: Behavior change support is important to reach personalized health goals in people with obesity. Since 2019, multiple evidence-based two-year combined lifestyle interventions (CLI), aimed at reducing weight-related health risks through behavior change, have been reimbursed by Dutch health insurance. It is unknown whether behavior changes obtained during a CLI persist after the program ends, and which behavior change techniques help to sustain healthy behavior. This study examines health and lifestyle outcomes up to 9 months post-CLI, aiming to provide insights into sustaining healthy lifestyle changes.

Methods: In this prospective cohort study, we used online questionnaires to assess multiple outcomes in individuals (BMI ≥ 30) who had recently completed a CLI. We measured health and lifestyle outcomes, including anthropometric data and behavioral outcomes, at four time points: directly after CLI (T0), and after 3 (T1), 6 (T2), and 9 (T3) months. Descriptive statistics and sum score calculations were calculated.

Results: The study sample (n=51; Female: 93%; mean age 56 yrs) included participants with an average Body Mass Index (BMI) of 34.3 at baseline and 33.7 at T2. Most participants (57%) maintained their eating habits 6 months post CLI, while 16% reported unhealthier habits, and 27% adopted healthier eating habits. Physical activity levels varied 6 months post CLI: 44% increased, 35% decreased and 21% remained unchanged. Participants were asked what helps them maintain their behavior. In summary, they indicated: seeing visible results of lifestyle changes, keeping goals in mind, having increased structure in day or week, feeling better due to lifestyle changes, experiencing accountability, and having action plans to sustain healthy behaviors. At the time of writing, results of T3 were not yet complete; however, complete results will be presented at the conference.

Conclusion: The preliminary findings show that BMI scores remained stable 6 months post CLI. Overall, the factors that helped participants sustain their healthy behaviors align closely with behavior change techniques, such as direct experience of positive outcomes, goal setting, self-monitoring, action planning, and social support. Findings emphasize the complexity of behavior change and the need for personalized, supportive approaches to maintain a healthy lifestyle.

II-P-B.05

Cardiorespiratory Fitness as Mediator in the Association between Physical Activity and Health-related Quality of Life in Patients with Cardiovascular Disease or Osteoarthritis

C. Schumacher¹, M. Wildekamp^{1,2}, J. Jelsma^{3,4,5}, I. Van den Akker-Scheek¹, A. Bouma⁶, R. Dekker⁷, M. Van Dijk^{8,4,5}, M. Van Hooft⁹, L. Te Loo^{8,4,10}, W. Van Mechelen^{8,4,5}, E. Portegijs², J. Zwerver^{2,11}, J. Vrijsen¹

¹University Medical Center Groningen, Orthopedics, Groningen, Netherlands, ²University of Groningen, Department of

B. MOTIVATION AND BEHAVIOR CHANGE

Human Movement Sciences, Groningen, Netherlands, ³Amsterdam UMC Location Vrije Universiteit, Department of Public and Occupational Health, Amsterdam, Netherlands, ⁴Amsterdam Public Health Research Institute, Health Behaviours & Chronic Diseases, Amsterdam, Netherlands, ⁵Amsterdam Public Health Research Institute, Quality of Care, Amsterdam, Netherlands, ⁶University Medical Center Groningen, Department of Strategy and External Relations, Groningen, Netherlands, ⁷University Medical Center Groningen, Department of Rehabilitation Medicine, Groningen, Netherlands, ⁸Amsterdam UMC location Vrije Universiteit, Department of Public and Occupational Health, Amsterdam, Netherlands, ⁹Máxima Medical Center, Department of Sports and Exercise, Veldhoven, Netherlands, ¹⁰Inholland University of Applied Sciences, Faculty of Health, Sports and Social Work, Haarlem, Netherlands, ¹¹Gelderse Vallei Hospital, Sports Valley, Sports Medicine, Ede, Netherlands

Purpose: Non-communicable diseases impact health-related quality of life (hr-QoL). In the general population, mental and physical aspects of hr-QoL are associated with physical activity (PA) and sedentary time (ST), where the measuring methods (device-based v.s. self-reported) may lead to variances within these associations. Cardiorespiratory fitness (CRF) may also play a significant role as higher CRF levels are linked to better hr-QoL, in both healthy and clinical populations. Therefore, this study aims to examine

- 1) associations between device-based and self-reported PA and ST, and hr-QoL, and
- 2) the influence of self-reported CRF in these associations in people with (or at risk for) CVD and/or OA.

Methods: Baseline data from the Lifestyle front Office For Integrating lifestyle medicine in the Treatment of patients (LOFIT) study was used. Participants included patients with (or at risk for) CVD and/or OA (n=273). PA and ST were measured using device-based (activPAL™) and self-reported methods (International Physical Activity Questionnaire – Short Form and Marshall Sitting Questionnaire). CRF was assessed by estimating peak oxygen uptake per kilogram bodyweight (VO2peak) using the FitMáx questionnaire. Hr-QoL was assessed using the EQ-5D-5L. Associations between PA, ST, CRF, and hr-QoL were examined using linear regression and mediation models.

Results: The average BMI of the participants was 34.0 kg/m² (SD=5.5) and the majority had CVD. Overall, the population was highly sedentary (mean 604.5 minutes sitting per day, SD=120.4). Higher levels of device-based, and self-reported PA were associated with higher hr-QoL (b=0.007, 95% CI=0.000, 0.013 per 1000 steps, b=0.001 95% CI= 0.000, 0.002 per 30 minutes). Higher levels of device-based and self-reported ST were associated with lower hr-QoL (b=-0.006, 95% CI=-0.012, -0.000 per 30 minutes, b=-0.004, 95% CI=-0.007, -0.001 per 30 minutes). An indirect path via CRF was observed in the association between PA and hr-QoL.

Conclusion: Higher PA and lower ST are associated with enhanced hr-QoL, where CRF influences the relationship between PA and hr-QoL in people with (or at risk for) CVD and/or OA. Changes in PA, ST or CRF behaviour should be realized within this population to enhance hr-QoL, which emphasizes the need for tailor-made interventions improving motivation and behavioural change.

II-P-B.06

Mapping Patient Experiences of Hospital-based Lifestyle Care: A Qualitative Study Using Patient Journey Mapping among Older Adults

A. Tebest¹, M.L. van Dijk¹, J.G. Jelsma¹

¹Amsterdam UMC, Public & Occupational Health, Amsterdam, Netherlands

Purpose: The aim of this qualitative study was to explore how older patients experience lifestyle-related care within a Dutch academic hospital setting. While lifestyle interventions are increasingly integrated into clinical care, little is known about how older patients perceive and navigate such care trajectories across multiple departments and disciplines. This study innovatively applies patient journey mapping as a participatory research method to visualize and analyze patient experiences of lifestyle care in a hospital context. By centering patient perspectives, the study seeks to identify opportunities to improve the design and delivery of lifestyle support within specialized care.

Methods: Semi-structured interviews were held in which we combined patient journey mapping with thematic analysis. Participants (inclusion criterium: aged 65 or older; having visited a hospital-based lifestyle front office in the past year) were asked to reflect on their experiences of lifestyle-related care. During the interview the journey maps were co-created. These maps captured the sequence of touch points, activities, stakeholders, experiences, emotions, and reflections associated with different stages of their hospital-based lifestyle care trajectory. Data analysis involved two complementary steps: (1) visual and narrative examination of the patient journey maps, and (2) thematic analysis of the interview transcripts to identify overarching themes and patterns in patient experiences. Coding software used was MAXQDA24.

Results: Analysis will be finished in December 2025 and final results will be presented by May 2026. Preliminary finding include a variety in experiences throughout the care pathway. Together, the journey maps and thematic

B. MOTIVATION AND BEHAVIOR CHANGE

insights are expected to illustrate how patients perceive the coherence, accessibility, and personalization of hospital-based lifestyle interventions.

Conclusion: This study contributes to the growing field of behavioral nutrition and lifestyle medicine by demonstrating the value of patient journey mapping as a tool for capturing the experiences of hospital-based lifestyle care. Insights from this research may inform more person-centered approaches to integrating lifestyle support into clinical pathways, particularly for older adults with complex health needs. The findings underscore the importance of aligning institutional care processes with patients' values, motivations, and capacities to sustain behavioral change.

II-P-B.07

Effects of an Active Break Intervention with Brain Gym on Work Environment Perception and Sedentary Behaviors in Administrative Health Staff: A Feasibility Intervention

E. Jauregui-Ulloa¹, J.M. Perez-Maravilla¹, J.Y. Ponce-Leon¹, J.A. Jimenez -Alvarado¹, R. Soria-Rodriguez¹

¹Universidad De Guadalajara, University Health Sciences Center, Guadalajara, Mexico

Purpose: To evaluate the effects of an intervention based on active breaks incorporating brain gym exercises on the perception of the work environment and patterns of sedentary behavior among administrative health staff.

Methods: A quasi-experimental pre-post study was conducted with an initial sample of 22 workers from the Department of Preventive Medicine. The intervention consisted of active break sessions with Brain Gym exercises in small spaces, lasting 7-10 minutes, three times per week for 9 months. Data collection was performed using two instruments: the OFFESS work environment questionnaire (Duncan et al., 2013) and the Occupational Sitting and Physical Activity Questionnaire (OSPAQ) (Chau et al., 2012), both adapted for the local context. The reliability and validity of the original instruments have been previously reported. The attrition rate was 9.1% (n=2). Statistical analysis included descriptive statistics (frequencies, percentages) and inferential analysis using Spearman's correlation test to assess associations between work environment variables and sedentary behaviors.

Results: Pre-intervention analysis (n=22) revealed a high prevalence of sedentary behavior, with 77.3% of workers remaining seated for 5 to 8 hours daily. Only 9.1% perceived movement spaces as „very adequate.“ Post-intervention analysis (n=20) showed a positive, statistically significant association between improved perception of the work environment and a higher frequency of sedentary breaks (Spearman's rho = 0.52, p < 0.05). Sixty percent of participants reported feeling „very good“ in their post-intervention environment, and 87.5% considered active breaks „very important.“ No substantial quantitative change was observed in self-reported total sitting time.

Conclusion: The implementation of an active break program with Brain Gym was significantly associated with improved perceptions of the work environment and increased frequency of sedentary breaks. Although perceptions of the environment and „breaks“ improved, self-reported total sedentary time did not show an apparent reduction. This strategy is feasible for promoting sedentary breaks and improving perceived well-being at work. More research is needed to explore the associations between different brain gym activities and well-being in work environments.

II-P-B.08

Understanding How Postnatal Mental Health Influences Engagement and Impact of a Postpartum Behavioural Weight Management Intervention: Qualitative Findings from the Supporting MumS (SMS) RCT

A. Ivory¹, D. Gallagher¹, E. Spyrelli¹, C. Kelly¹, M. McKinley¹

¹Queen's University Belfast, School of Medicine, Dentistry and Biomedical Sciences, Belfast, United Kingdom

Purpose: Mental health conditions, such as anxiety and depression, are common in the postpartum period and are associated with postpartum weight retention. However, few postpartum behavioural weight management interventions consider how mental health influences outcomes. The Supporting MumS (SMS) randomised controlled trial examined the effectiveness of an automated, text message-delivered behavioural intervention to support weight management for postpartum women with overweight or obesity in 892 women from across the UK. Qualitative interviews explored the mental health experiences of intervention participants and how this influenced engagement and impact of the intervention.

B. MOTIVATION AND BEHAVIOR CHANGE

Methods: Semi-structured interviews were conducted with a purposive sample of intervention group participants via telephone or MS teams at 6 and 12 months. Purposive sampling was based on study site, baseline weeks postpartum, parity, ethnicity, socioeconomic status, and Edinburgh Postnatal Depression Scores (EPDS). Interviews were audio-recorded, transcribed verbatim and then pseudonymised. Data were analysed thematically using NVivo.

Results: Forty-nine participants completed interviews at 6 (n=33) and 12 (n=16) months. Purposive sampling ensured inclusion of a wide diversity of sample characteristics. Nearly half of the sample (48.9%) had a high EPDS score (> 9) at baseline. Many women voiced that poor mental health reduced their engagement with the intervention and their ability to enact specific behaviour change techniques, negatively impacting behaviours such as eating patterns and physical activity. Women described how they felt receiving the intervention had enhanced their mental wellbeing through provision of emotional support and increased self-esteem and self-advocacy. This, in turn, boosted motivation for engaging in physical activity and making healthier choices. For some participants, prioritising their mental health meant choosing not to engage with the intervention, for example to avoid guilt. Whereas for others, the intervention gave them “something positive to focus on” when they were struggling with their mental health.

Conclusion: Findings highlight the complexity of the relationship between mental health and health behaviours, particularly in this vulnerable population. Consideration of mental wellbeing as part of behaviour change interventions may enhance engagement and improve health outcomes. It is important to monitor the impact of behavioural interventions on mental health in terms of benefits and potential harms.

II-P-B.09

Exploring Health-related Behaviour Patterns in Remote Call Centre Workers; A STROBE Compliant Cross-sectional Study

C. Harpham¹, S. Clemes¹, N. Paine¹, M. Fray², K. Mehta¹, M. Sayyah¹, E. Stamp¹

¹Loughborough University, School of Sport, Exercise and Health Sciences, Loughborough, United Kingdom, ²Loughborough University, School of Design and Creative Arts, Loughborough, United Kingdom

Purpose: Since Covid-19, remote working has increased. Remote working can lead to reduced physical activity (PA), increased sedentary time, and poor diet. Call centre workers are particularly vulnerable, spending more of their workday sedentary than those in other sectors. However, the impact of remote working on this already at-risk population is unknown. This study explored the health-related behaviour patterns of remote call centre workers (RCCW), to support the planning of a future intervention. A secondary aim was to explore associations between PA and work performance.

Methods: A cross-sectional study was conducted with RCCW from a UK charity. An online questionnaire including demographics, physical and psychological health measures, and anthropometrics was completed. Participants wore an activPAL v4 over eight consecutive days, completed a daily log (working hours, sleep time, self-rated work performance), and recorded dietary intake via a smartphone app. Paired t-tests or Wilcoxon tests compared working days (WDs) and non-working days (NWDs) for aspects including sitting time, prolonged sitting bouts, steps, and calorific intake. WD data were analysed to identify inactive periods. Pearson's correlation assessed the relationship between PA and performance.

Results: Forty-two RCCW (93% female, mean/SD age 51.5 ± 9.1 years) were recruited; 35 provided valid activPAL data, and 19 recorded dietary intake. BMI was elevated (29.6 ± 6.7 kg/m²), and 75% reported musculoskeletal pain. During waking hours, RCCW spent significantly more time sitting on WDs (74.5% ± 9.8) than NWDs (60.9% ± 9.7, p<.001), and in prolonged sitting bouts >30-60 (p<0.001) and >60 minutes (p<0.001). Total steps were less on WDs (median {IQR} 5109 {4002-7418} steps/day) than NWDs (9338 {6327-1462}, p<0.001). Calorific intake did not differ between WDs and NWDs. The most inactive WD periods were occupational periods either side of lunch, with over 86% of time spent sitting. A small-to-moderate correlation (r=0.32, p=0.029) was found between increased WD PA and performance.

Conclusion: RCCW are more sedentary on WDs than NWDs, particularly during occupational periods before and after lunch. Future qualitative research is needed to understand the experiences of RCCW lifestyle behaviours. Together, this can inform the development of tailored interventions to target prolonged inactive periods to improve health and potentially work performance.

B. MOTIVATION AND BEHAVIOR CHANGE

II-P-B.11

A Nutrient Profiling Model for Addressing Paraguay's Nutritional Challenges

A. Ushiwata¹, S. Kamigauchi¹, G.G. Candia V.², Y. Caballero²

¹Kitasato University, Department of Clinical Medicine (Biostatistics), School of Pharmacy, Tokyo, Japan, ²Utsunomiya University, Cooperative Faculty of Education, Utsunomiya, Japan

Purpose: In Paraguay, inadequate nutrition education persists, and people continue to die from non-communicable diseases caused by obesity. Nutrient profiling models that can visually assess a food's nutritional value are used worldwide, allowing individuals to select nutrient-dense foods even without comprehensive nutrition education. Using this model in Paraguay may facilitate the selection of nutrient-dense foods, thereby promoting dietary behavioral changes. This study aimed to develop a nutrient profiling model based on Paraguay's nutritional challenges.

Methods: Between September and November 2023, a dietary survey using direct weight measurements was conducted in Paraguay. Average recipes for 28 food items and dishes were calculated from these records and categorized into three dietary groups associated with obesity: "traditional dishes prepared with meat," "processed wheat flour-based foods," and "carbohydrate-rich traditional dishes." Based on Paraguay's nutritional challenges, key nutrients were selected and weighted relative to their reference intake to create a Nutrient Rich Food (NRF) score. The calculated scores were then classified into five categories: "excellent," "good," "average," "poor," and "very poor," and compared across the dietary groups.

Results: Among the 22 items for which NRF scores could be calculated from average recipes, the highest value was for boiled cassava (66.7) in the carbohydrate-rich group, and the lowest was for fried dumpling with meat and boiled egg (empanada) (-6.0) in the meat group. The five items classified as "excellent" were from the carbohydrate-rich group. Nine items classified as "poor" or "very poor" were dishes containing fried, cheese, or processed foods.

Conclusion: The nutrient profiling model constructed based on the nutrients affecting obesity revealed that dishes containing fried, cheese, and processed foods had poor scores. Since the scores were calculated using average recipes, calculating the scores for each individual recipe could provide a more detailed understanding of the nutritional value.

II-P-B.12

Perceptions of Nature Contact across Environments in American Adults

J. Maddock¹, M. Patterson¹, A. Price²

¹Texas A&M University, Center for Health & Nature, College Station, United States, ²Sacred Heart University, Health Sciences, Fairfield, United States

Purpose: Physical activity (PA) in natural settings provides additional mental health benefits than PA performed indoors. People who live near natural settings, like greenspaces, are also more physically active. As we communicate the benefits of spending time in nature to the public, it is essential to understand what "time in nature" means to them; to date, there is little agreement. The goal was to assess how nature-rich various environments were perceived to be.

Methods: American adults were recruited to participate in an on-line survey through Prolific. Respondents (n=303) rated 16 environments on a scale from 0 (no nature contact) to 100 (complete and full nature experience), reflecting the degree to which each environment would be considered time in nature. These 16 items were grouped into three subscales measuring different types of nature: wild nature (e.g., National parks), curated nature (e.g., zoos), and mediated nature (e.g., virtual reality). Participants also reported their time in nature over the past week, nature connectedness, and demographics.

Results: Only 5 environments had a mean greater than 50, including State or National Parks (M=90.8), ponds, lakes, streams or other bodies of water (M=84.6), local parks (M=74.6), botanical gardens (M=73.2), and home yards or gardens (M=61.5). Mediated experiences ranked the lowest and included: virtual reality nature (M=13.1), videos of nature (M=15.8), nature art (M=17.3), and recorded nature sounds (M=19.1). The standard deviations were high (>20) for 14 of the 16 items. For subcategories, wild nature had the highest endorsement (M=83.3), followed by curated nature (M=43.4) and mediated nature (M=16.3). Nature connectedness was significantly correlated ($p < .05$) with all three subscales (wild $r = .20$, curated $r = .20$ and mediated $r = .16$). Females rated curated nature higher than males. Black Americans rated mediated nature twice as high as other racial/ethnic groups.

Conclusion: While most respondents agreed that wild nature counted as spending time in nature and mediated nature did not, there was substantial disagreement for curated nature. Black Americans rated mediated nature much higher than other respondents. Black Americans get less physical activity than their White counterparts, mediated activities are typically sedentary and may exacerbate this trend.

B. MOTIVATION AND BEHAVIOR CHANGE

II-P-B.13

Exploring the Effects of Psychedelic Microdosing on Health Behaviour Change

J. Encantado¹, L. Prochazkova^{1,2}, L.C. Carvalho¹, N. Marrouch^{1,3}, P. J. Teixeira¹

¹Faculdade de Motricidade Humana, Universidade de Lisboa, Behavioral Regulation, Lisboa, Portugal, ²Institute of Psychology, Leiden University, Cognitive Psychology Unit, Leiden, Netherlands, ³University of Connecticut, Institute for the Brain and Cognitive Sciences, Storrs, United States

Purpose: Psychedelic research has predominantly examined high-dose applications for psychiatric conditions such as depression and anxiety, but emerging perspectives suggest broader applicability. Teixeira et al. (2022) propose that psychedelics may facilitate health behavior change by disrupting maladaptive patterns across general populations, prompting the conceptualization of „behavioral psychedelics“—defined as the application of psychedelics to promote intentional habit modification and enhance health and resilience (Neuhaus and Slavich, 2022). Classic psychedelics (e.g., psilocybin, LSD) function as serotonin 5-HT_{2A} receptor agonists, inducing alterations in neural connectivity and enhancing neuroplasticity. Despite the growing prevalence of psychedelic microdosing as a self-directed wellness intervention, empirical evidence regarding its impact on health behavior change remains limited. This study examined self-reported change in health-related behaviors and explored potential psychological mechanisms underlying these changes among individuals engaging in naturalistic psychedelic microdosing.

Methods: A retrospective cross-sectional survey utilizing mixed methodologies was administered to 365 participants with prior psychedelic microdosing experience. Participants provided both quantitative and qualitative data regarding perceived changes in health behaviors and hypothesized psychological mechanisms attributable to microdosing practice. Qualitative data underwent thematic analysis, while logistic regression models examined relationships between behavioral modifications and individual-level and contextual predictor variables.

Results: The sample comprised 365 participants (mean age of 44.59 years [SD = 11.77]), with a gender distribution of 187 males (51.23%), 174 females (47.67%), and three non-binary individuals (0.82%). The most prevalent self-reported behavioral modifications included enhanced sleep quality (47.1%, n = 172), increased engagement in contemplative practices (46.8%, n = 171), elevated physical activity levels (44.1%, n = 161), improved work-life balance (37.5%, n = 137), and augmented social activity participation (37.3%, n = 136). Behavioral change intention demonstrated the strongest predictive association with reported outcomes, whereas dosage parameters, dosing protocols, and psychiatric diagnostic status did not significantly predict behavioral change. Thematic analysis revealed several candidate psychological mechanisms, including enhanced mental health status, improved cognitive clarity, heightened self-awareness, increased autonomous motivation, and strengthened interpersonal connection.

Conclusion: These findings offer preliminary insights into health behavior modifications associated with psychedelic microdosing. Prospective controlled investigations are warranted to elucidate whether and how microdosing protocols may be optimally integrated into intentional health promotion interventions.

II-P-B.14

Motivation, Enjoyment, and Exercise Motives in Fitness-class Participants

L. Cerca¹, A. Palmeira¹, D. Teixeira¹, H. Pereira¹

¹Universidade Lusófona, CIDEFES, Lisboa, Portugal

Purpose: Self-Determination Theory (SDT) posits that more autonomous forms of motivation enhance positive affective responses to exercise, particularly enjoyment, which is pivotal for sustained participation. This study examined how motivational regulations and exercise motives are associated with enjoyment among adults attending fitness classes.

Methods: Participants completed an online survey including the BREQ-4 (assessing amotivation, external, introjected, identified, and integrated regulations to compute a Relative Autonomy Index, RAI), the EMI-2 (evaluating health, appearance, enjoyment, affiliation, strength/fitness, stress management, weight management, and challenge/competition motives), and the PACES (measuring exercise enjoyment). All available responses were analyzed using pairwise completion when appropriate. Scale scores were computed following standard scoring guidelines, and internal consistency was examined using Cronbach's α . Relationships between RAI, PACES, and EMI-2 motives were analyzed through Pearson correlations, applying the Benjamini–Hochberg FDR correction for multiple comparisons.

Results: The analytic sample comprised 114 adults (67.5% women). Internal consistency was acceptable to good for several measures: BREQ-identified ($\alpha=0.78$), BREQ-intrinsic ($\alpha=0.66$), and PACES ($\alpha=0.64$). Within EMI-2, challenge/competition showed strong reliability ($\alpha=0.87$), while enjoyment and appearance were acceptable ($\alpha=0.65$ and $\alpha=0.63$),

B. MOTIVATION AND BEHAVIOR CHANGE

and health was marginal ($\alpha=0.55$). Correlational analyses aligned with the SDT framework, linking more autonomous regulation and enjoyment-related motives to higher PACES scores. Findings supported this hypothesis—enjoyment constructs clustered together—though some effects involving BREQ-4 subscales were weaker due to incomplete item coverage and should be interpreted cautiously.

Conclusion: Among fitness-class participants, enjoyment demonstrated satisfactory psychometric properties and was conceptually associated with autonomous motivation and enjoyment-oriented motives, consistent with SDT tenets. These findings highlight the practical relevance of fostering autonomy-supportive contexts and enjoyable class experiences to enhance long-term adherence. Future studies should apply validated Portuguese scoring protocols and longitudinal designs to clarify causal pathways between motivation and enjoyment.

II-P-B.17

Beliefs Shape Behaviour: A Qualitative Grounded Theory Study on Beliefs of People with First-ever Stroke About 24-hour Movement Behaviour

C.F. Biemans^{1,2,3}, M. Weren¹, N. Koenders⁴, O.W. Verschuren^{1,2,5}, C. Veenhof^{2,6}, J.M. Visser-Meily^{2,5}, Y.A. Hartman^{1,2,3}, M.F. Pisters^{1,2,3}

¹Fontys University of Applied Sciences, Department of Health Innovations and Technology, Research group Empowering Healthy Behavior, Eindhoven, Netherlands, ²University Medical Center Utrecht, UMC Utrecht Brain Center, Department of Rehabilitation, Physiotherapy Science & Sport, Utrecht, Netherlands, ³Center for Physiotherapy Research and Innovation in Primary Care, Julius Health Care Centers, Utrecht, Netherlands, ⁴Radboud University Medical Center, Department of Rehabilitation, Nijmegen, Netherlands, ⁵Center of Excellence for Rehabilitation Medicine, Brain Center, University Medical Centre Utrecht and De Hoogstraat Rehabilitation Utrecht, Utrecht, Netherlands, ⁶University of Applied Sciences Utrecht, Research Group Innovation of Human Movement Care, Utrecht, Netherlands

Purpose: There is growing global recognition that a balanced 24-hour movement behaviour pattern, comprising sedentary behaviour, physical activity and sleep, is a key determinant of health. Beliefs may shape their 24-hour movement behaviour pattern. This study aimed to explore beliefs of people with first-ever stroke about sedentary behaviour, physical activity and sleep.

Methods: A qualitative, grounded theory study was performed using face-to-face, semi-structured interviews in people with first-ever stroke. Purposeful sampling was used based on 24-hour movement behaviour pattern, age, gender, cognitive status and body mass index. Two independent analysts applied initial, focused and selective coding to construct a conceptual model.

Results: Eighteen people with stroke were interviewed. Selective code “Balance” indicated that people believe that they need to alternate between sitting, moving and sleeping to cope with daily demands. “Importance” captured the belief that physical activity contributes to health and sleep aids recovery and rest, whereas sitting is seen as unimportant. “Emotions” showed how emotions shape activity, and vice versa. “Context” reflected how participants believe that physical, social, cultural and medical context shape their 24-hour movement behaviour pattern. The conceptual model showed that participants were aware of the health benefits of physical activity, which often translated into consciously participating in physical activity. Beliefs about sedentary behaviour, sleep and balance in 24-hour movement behaviour were limited or lacking.

Conclusion: Beliefs about sedentary behaviour, physical activity and sleep - shaped by balance, importance, emotions, and context - are perceived to influence the 24-hour movement behaviour pattern after stroke. Behaviour interventions targeting 24-hour movement behaviour after stroke should consider these beliefs. The limited beliefs about sedentary behaviour and 24-hour balance indicate a need for broader (public) awareness and education about the importance of striking the balance in 24-hour movement behaviour.

II-P-B.18

Feasibility of a Low-dose Physical Therapy Model to Promote Exercise in People with Multiple Sclerosis

D. Kinnett-Hopkins¹, C.-C. Lin¹, D. Ryan², M. Hendricksen³, M. Rafferty³

¹University of Michigan, Kinesiology, Ann Arbor, United States, ²Michigan Medicine, Physical Therapy, Ann Arbor, United States, ³Shirley Ryan AbilityLab, Chicago, United States

B. MOTIVATION AND BEHAVIOR CHANGE

Purpose: Despite strong evidence supporting exercise to alleviate symptoms in persons with multiple sclerosis (MS), engagement rates remain low. Traditional physical therapy (PT) often focuses on function restoration following disability rather than proactive prevention of morbidity advancement. This feasibility study explored a low-dose, consultative PT model designed to increase exercise behavior and improve MS-related symptoms.

Methods: In a single-arm, pre-post design, participants attended six in-person PT visits over six months (Weeks 0, 2, 6, 10, 16, 24). The intervention provided individualized exercise prescription, education, and goal-setting, promoting home-based aerobic and strengthening to achieve MS-specific physical activity guidelines by the study completion. The primary outcome was the Godin Leisure-Time Exercise Questionnaire (GLTEQ). Secondary outcomes included patient-reported PROMIS measures (fatigue, pain, sleep, anxiety, depression) and MS-specific scales (MSWS-12, MSIS-29, Late-Life Function and Disability Instrument (LLFDI)).

Results: Thirteen of 16 participants completed the study (81% retention). GLTEQ scores significantly increased ($p=0.05$), with participants moving from moderately active (Mean=17.62) to sufficiently active (Mean=29.62). LLFDI also showed a statistically significant trend ($p=0.05$). No significant changes were found for MSWS-12, MSIS-29, or PROMIS measures; however, moderate effect sizes were noted for GLTEQ (Cohen's $d=0.55$), LLFDI ($d=0.36$), and psychological impact of MS ($d=-0.35$), denoting clinically meaningful improvements. All participants rated the program as highly acceptable and appropriate, and unanimously indicated they would recommend it to others with MS.

Conclusion: This feasibility study demonstrates that a low-dose, consultative PT model is a promising strategy for persons with MS. Significant gains in self-reported exercise and functional trends highlight its potential for broader implementation. This approach is reimbursable under current U.S. healthcare models, supporting scalability. Larger, randomized controlled trials are justified to confirm benefit and establish best practice for MS management.

II-P-B.19

Experiences with Participatory Support in Facilitating Sustainable Behavior Change: A Qualitative Thematic Analysis Protocol

S. Broers^{1,2}, M. Trogrlic^{1,2}, J.M. Visser-Meily^{1,3}, Y.A. Hartman^{1,2,4}, M.F. Pisters^{1,2,4}

¹UMC Utrecht Brain Centre, University Medical Centre Utrecht, Department of Rehabilitation, Physiotherapy Science & Sport, Utrecht, Netherlands, ²Julius Health Care Centers, Centre for Physiotherapy Research and Innovation in Primary Care, Utrecht, Netherlands, ³University Medical Centre Utrecht and De Hoogstraat Rehabilitation Utrecht, Centre of Excellence for Rehabilitation Medicine, Brain Centre, Utrecht, Netherlands, ⁴Fontys University of Applied Sciences Physiotherapy School of Health Sciences, Research group Empowering Healthy Behaviour, Department of Health Innovations and Technology, Eindhoven, Netherlands

Purpose: Secondary prevention is crucial to reduce stroke recurrence and improve long-term outcomes. Lifestyle interventions are central to this process, but long-term success depends on achieving sustainable behavioral change. Such change requires emotional and psychosocial support that extends beyond medical care. These forms of support are most effective when provided by individuals within a person's close social network but are often underutilized. Therefore, the RISE (*Reduce and Interrupt Sedentary behavior using a blended behavioral intervention to Empower people at risk towards sustainable 24-hour movement behavior change*) intervention introduces the novel concept of participatory support, reimagining the role of these close others as equal partners in lifestyle interventions and facilitates sustainable behavior change after stroke.

Methods: A qualitative thematic analysis will be conducted to explore the experiences and perceived negative and positive value of *participatory support* in facilitating sustainable behavior change within a *movement-focused intervention*, from the perspectives of stroke survivors and their partners. Individual semi-structured interviews will be conducted with stroke survivors and partners who have completed the 15-week RISE intervention. Sampling starts with a convenience approach, supplemented by purposive sampling to ensure variation in stroke survivors' gender, age, and cognitive status, as well as the partner's level of involvement and nature of the relationship (e.g. partner, child, sibling). Data will be analyzed through open, focused, and selective coding. Two independent researchers will carry out the analysis, engaging in discussions to enhance reflexivity and ensure consistency in theme development. Emerging themes will be finalized through consensus meetings with the extended research group.

Results: -

Conclusion: Implications: Participatory support is a novel concept in healthcare practice, with limited evidence on its effectiveness and the experiences of those involved. This study will explore how stroke survivors and their partners perceive and value participatory support, highlighting key conditions for successful implementation within post-stroke lifestyle interventions. Findings may guide new collaborative approaches, enabling patients and partners to take a more active, equal role in rehabilitation and promote sustainable behavior change. Moreover, these insights

B. MOTIVATION AND BEHAVIOR CHANGE

may serve as the first building blocks for the further development and implementation of participatory support within the broader context of healthcare practice.

II-P-B.20

Understanding Physical Activity Experiences among Individuals with Multiple Sclerosis in Saudi Arabia: A Qualitative Study

R. Barboud^{1,2}, U. Jones², S. Roberts², J. Latchem-Hastings²

¹Taif University, Department of Physical Therapy, Taif, Saudi Arabia, ²Cardiff University, School of Healthcare Sciences, Cardiff, United Kingdom

Purpose: Physical activity (PA) engagement remains limited among individuals with multiple sclerosis (MS), despite its established physical and psychological benefits. Limited evidence exists regarding PA experiences of individuals with MS in Saudi Arabia. This study explored the experiences, barriers, and facilitators of PA among individuals with MS in Saudi Arabia.

Methods: A qualitative case study design using semi-structured interviews was conducted. Eighteen individuals with mild-to-moderate MS (6 males and 12 females) were recruited through purposive sampling from Saudi Arabia. Interviews were conducted face-to-face or via Zoom, audio-recorded, transcribed verbatim, and translated into English. Data were imported into NVivo 14 and analysed inductively using Braun and Clarke's six-phase reflexive thematic analysis. Ethical approval was obtained, and informed consent was secured from all participants.

Results: Preliminary thematic analysis identified six major themes influencing PA engagement among individuals with MS: (1) living within MS boundaries, (2) motivational dynamics, (3) social relationships, (4) knowledge gaps and information navigation, (5) cultural influences, and (6) environmental and structural barriers.

MS-related symptoms, particularly fatigue, substantially limited participation despite awareness of PA importance; however, participants employed coping strategies to navigate these challenges. Key motivational facilitators included self-efficacy, future-oriented goals, perceived physical and psychological benefits, and accountability through group exercises or self-monitoring, while lack of enjoyment, low intrinsic drive, and time constraints demotivated participation. Social relationships had dual influences: family support and peer encouragement facilitated engagement, while overprotection and social stigma discouraged it. Regarding knowledge and information, inadequate and inconsistent guidance from healthcare professionals created uncertainty about appropriate activity levels and prompted information-seeking through peer networks and online resources. Cultural influences constrained PA through sedentary lifestyle norms and gender expectations, yet growing public awareness of PA and increased support for women's participation represented cultural shifts supporting PA engagement. Finally, extreme heat, limited accessibility, high costs, and lack of inclusive facilities further limited opportunities for sustained engagement.

Conclusion: These preliminary findings highlight the complex, multifactorial influences shaping PA engagement among individuals with MS in Saudi Arabia. Results will inform the development of culturally tailored, evidence-based interventions to promote and sustain PA participation in this population.

II-P-B.21

Running Wild: Forest Running Enhances Performance, Enjoyment, Mood and Future Exercise Intentions

M. Putland¹, D. Longman¹, C. Shaw², S. Bailey¹, S. Clemes¹, B. Christmas¹, E. Willems², Y.L. Ho¹, E. Jones¹, A. Lintuluoto³, R. Naik¹, H. Lal Rahimi¹, H. Xiang¹

¹Loughborough University, School of Sport, Exercise and Health Science, Loughborough, United Kingdom, ²University of Zurich, Department of Evolutionary Anthropology, Zurich, Switzerland, ³CERN, Geneva, Switzerland

Purpose: Physical inactivity remains a global public health crisis, driving non-communicable disease and generating billions of dollars in healthcare costs annually. While nature-based physical activity (PA) is theorised to enhance both the quantity and quality of PA, empirical evidence remains limited. Drawing on the recently proposed Environmental Mismatch Hypothesis - which posits that natural environments may optimise physical performance due to evolutionary adaptations - we hypothesised that forest-based exercise would improve performance, enjoyment, mood and future PA intentions compared to urban exercise.

Methods: Forty-seven healthy adults (31 male; mean±SD age: 25±3 years; BMI 22.8±2.5kg/m²) completed a randomised, counterbalanced crossover trial involving a 30-minute self-paced run/walk at a prescribed moderate intensity (target

B. MOTIVATION AND BEHAVIOR CHANGE

perceived exertion = 4 on the Borg CR10 scale of 0-10) in a forest and urban environment. Outcomes included distance covered, heart rate (HR), enjoyment (PACES), mood (Profile of Mood States) and short- and long-term intentions to repeat the activity. Data were analysed using linear mixed-effects models with environment, sex and trial order as fixed effects and participant ID as a random effect.

Results: Participants ran significantly further in the forest compared with the urban condition (+171m; $F(1,46) = 5.3$, $p = 0.025$, Cohen's $d = 0.2$), despite more challenging terrain. This performance enhancement occurred without increases in HR or perceived exertion. Forest-based exercise also elicited greater enjoyment ($F(1,91) = 67.479$, $p < 0.001$; $d = 1.5$), improved post-exercise mood ($F(1,138) = 24.594$, $p < 0.001$; $d = 0.7$) and stronger short- and long-term intentions to engage in future PA (short-term $F(1,89) = 131.724$, $p < 0.001$; $d = 2.4$; long-term: $F(1,89) = 114.856$, $p < 0.001$; $d = 2.2$). Enjoyment was a strong predictor of future PA intentions, independent of environment and mood. Effects were consistent across sex, age, BMI, baseline fitness, and environmental preference.

Conclusion: A single bout of forest-based exercise enhanced performance and affective responses without additional physiological strain. These findings suggest that natural environments may facilitate higher quality PA and foster intrinsic motivation for sustained engagement. Nature-based interventions could therefore represent an effective, scalable strategy to reduce physical inactivity and improve population health.

II-P-B.22

Impact of Two Short Behavioral Theory-driven Professional Training Programs Targeting Attendance in Fitness Centers: Protocol for a Randomized Controlled Trial

D. Teixeira^{1,2,3}, P. Ekkekakis⁴, H. Elsangedy⁵, V. Bastos^{1,2,3}

¹Lusófona University, Faculty of Physical Education and Sport, Lisbon, Portugal, ²Research Center in Sport, Physical Education, Exercise and Health, Lisbon, Portugal, ³Centre for Research, Training, Innovation and Intervention in Sport, Porto, Portugal, ⁴Michigan State University, Department of Kinesiology, East Lansing, United States, ⁵Federal University of Rio Grande do Norte, Department of Physical Education, Natal, Brazil

Purpose: Fitness centers are privileged settings for promoting population health; however, they are affected by high attrition rates and low attendance. At the same time, several motivational theories are claimed to be relevant for behavioral improvement in exercise contexts, although they are virtually devoid of experimental evidence in this regard. As such, the main objective of this study is to analyze the impact of two short training programs, designed for exercise professionals and based on two theories of human behavior (self-determination theory [SDT] and hedonic theory [HT]), on fitness center adherence. As a secondary objective, the study will examine the impact of these trainings on attrition rates, motivational variables, and other behavioral outcomes.

Methods: This is a pre-registered, randomized, controlled, pragmatic, single-blind trial with three parallel arms and an allocation ratio of 1:1:1. Professionals will receive a short training session at the start of the sports season, according to their assigned arm (SDT, HT, and general prescription guidelines as control), followed by successive reinforcement sessions every 10–12 weeks. From September 2025 to August 2026, data on new memberships, dropouts, and training attendance among new clients will be collected. A subsample of 114 exercisers will be assessed over one year to monitor motivational profiles.

Results: The primary outcomes will be exercise frequency; secondary outcomes will include attrition rate, motivation, intention to continue exercising, behavioral automaticity, subjective affective experience, and enjoyment. Agreement with exercise intensity, self-control state, and ratings of the extent and frequency of training content application will be used as control variables.

Conclusion: Improvements in exercise frequency would reflect individual health gains; reductions in attrition rates would enhance the financial sustainability of fitness clubs. Moreover, the findings would simultaneously validate hypotheses concerning the utility and validity of prominent behavioral theories and reinforce the importance of modifying current approaches in these contexts.

B. MOTIVATION AND BEHAVIOR CHANGE

II-P-B.23

Using Street Art as a Novel Approach to Physical Activity Messaging in South Africa

P. Gradidge¹, M. Phaswana¹

¹University of the Witwatersrand, Department of Exercise Science and Sports Medicine, Johannesburg, South Africa

Purpose: Low-resource settings such as South Africa often report the highest levels of insufficient physical activity, yet traditional surveillance methods fail to capture comprehensive data. Consequently, health promotion strategies struggle to sustain the attention of adults. Public street art is a common cultural expression. It remains an underutilised medium for contextual health messaging that integrates active living into daily routines. Leveraging existing public spaces, outward-facing artwork can transform zones with high foot and vehicle traffic into areas of connection for people, curiosity, and reflection, aligning with global frameworks for physical activity promotion. This study explores whether mural street art can engage adults at a South African university in conversations about movement, and whether such engagement translates into increased awareness and participation in physical activity.

Methods: Murals will be co-designed with local artists, embedding evidence-based imagery related to movement and active living. The murals will be painted on a wall in a known high-density zone at a South African institution. Engagement will be assessed through observational metrics, including time spent interacting with murals, photography, and social media sharing. The interactions will be collated and coded into themes for analysis.

Results: The mural street art is anticipated to lead engagement, curiosity, social connection, and dialogue in person and on social media, around movement and active living.

Conclusion: In low-and-middle income contexts with significant physical inactivity, integrating mural street art as a cultural expression with public health messaging offers a novel, and inclusive approach to promoting active living.

II-P-B.24

A culturally tailored comic series to promote everyday physical activity in South Africa

M. Phaswana¹, P. Gradidge¹

¹University of the Witwatersrand, Department of Exercise Science and Sports Medicine, Johannesburg, South Africa

Purpose: Sedentary behaviour is a well-established independent contributor to non-communicable diseases and has emerged as a global public health concern. South African universities are no exception: staff and students' work often involves prolonged sitting, which is particularly concerning given the prevalence of obesity in this setting. Despite this, there is limited evidence on effective strategies to promote movement whilst reducing sedentary behaviour in these settings. This study aims to design and implement a compelling video content campaign to reduce sedentary behaviour and promote regular movement. Therefore, addressing barriers such as social norms, perceptions, and environmental constraints and showcasing practical solutions, this approach offers a scalable model for shifting attitudes toward movement and fostering inclusive spaces for physical activity. Evidence indicates that culturally relevant video media can play a pivotal role in health communication by turning research findings into actionable behaviours.

Methods: This exploratory campaign's core message is that 'every move counts', emphasising the integration of movement throughout waking hours, such as walking during lunch breaks, standing during phone calls, taking the stairs, active commuting, and even short movements. A brief, visually engaging video that educates and encourages reflection on personal habits. Engagement metrics, including video views, shares, and comments, will be collected to determine reach and initial impact. Descriptive statistics will be used to analyse engagement data, and thematic coding of user responses will be used to identify shifts in awareness and attitudes.

Results: Data analysis will focus on reach, engagement, and indicators of behavioural intention, such as expressed willingness to integrate movement into daily routines and advocate for supportive environments.

Conclusion: Findings will yield novel insight into the efficacy of a visually engaging video campaign in fostering active lifestyles. Leveraging social norms and digital platforms, these campaigns offer scalable solutions to encourage movement-related behaviours.

B. MOTIVATION AND BEHAVIOR CHANGE

II-P-B.25

The Feasibility of Detecting Leg Fidgeting Using Wearable Sensors and Estimating Its Energetic Cost via Indirect Calorimetry

A. Narayanan¹, M. Wood¹, S. Duncan¹, T. Stewart¹, J. Gale

¹Auckland University of Technology, Human Potential Centre, Auckland, New Zealand

Purpose: Leg fidgeting, characterised by rhythmic lower limb movement while seated, is a spontaneous, low-intensity behaviour that may serve as a practical strategy to interrupt prolonged sedentary time. This study aimed to evaluate the feasibility of detecting leg fidgeting using a wearable thigh-mounted accelerometer, and to quantify its energetic cost in comparison to sitting, standing, and slow walking under controlled settings.

Methods: Fifteen healthy adults (mean age = 35.6 ± 12 years; 33.3% male) completed semi-structured five-minute bouts of sitting, fidgeting, standing, and slow walking while wearing a thigh-mounted accelerometer (SENS motion system). Behaviour classification was validated against direct observation, and energy expenditure was measured using breath-by-breath indirect calorimetry. The SENS classification of fidgeting was evaluated using sensitivity, specificity, and balanced accuracy metrics. Energy expenditure was compared across activities using linear mixed-effects models, controlling for age, gender, and BMI.

Results: A total of 305 mins of activity data were recorded. Balanced accuracy for activity classification ranged from 90.6% (slow walking) to 99.1% (standing), with fidgeting classified at 95.0%. The energy expenditure of fidgeting (mean = 1.69 kcal/min) was significantly different from sitting (1.49 kcal/min), standing (1.47 kcal/min), and slow walking (mean = 4.10 kcal/min).

Conclusion: This study demonstrates that leg fidgeting can be detected using wearable sensors under controlled conditions. Furthermore, leg fidgeting expends slightly greater energy than expenditure compared to sitting and standing. Future research should examine its metabolic relevance in free-living settings and explore its role in daily movement patterns and in strategies to reduce prolonged sedentary time.

II-P-B.26

Impacts of Working from Home on Sedentary Behaviour, Physical Activity and Diet in the Post Pandemic Era- a Within-subject Measures Study in Hybrid Workers

K. Mehta¹, S. Clemes¹, N. Paine¹, M. Sayyah¹, E. Stamp¹

¹Loughborough University, Loughborough, United Kingdom

Purpose: The prevalence of home/remote working has increased significantly post pandemic, leading to concerns about potential negative impacts on sedentary behaviour, physical activity, and dietary habits within remote/hybrid workers. Limited research has examined these behaviours in the post-pandemic context, however. This study examined whether differences existed in sedentary behaviour, physical activity, and dietary intake between home and office working days in hybrid workers.

Methods: Sedentary behaviour, physical activity and dietary intake were measured over 8-consecutive days using a thigh-worn accelerometer (activPAL micro 3) and diet diary (Nutritics app), in a sample of desk-based hybrid workers. Participants recorded their time in bed, sleep time, working hours and work location in a daily log. Participants were required to provide valid activPAL data on at least one work from home and one office day for inclusion in the analyses. Lifestyle behaviours were compared between home and office working days using either paired sample t-tests or Wilcoxon signed-rank tests.

Results: Of 111 consenting hybrid workers, 88 (79%) provided valid activPAL data (67% female; mean (SD) age: 36 (13) years; BMI: $24.8 (4.6) \text{ kg/m}^2$). Waking wear time was significantly higher on office days compared to home working days (15.8 vs 15.4 hours/day, $p < 0.05$). The proportion of sitting time was significantly higher on home working days in comparison to office days (70% vs 67%, $p < 0.05$), while step counts were significantly lower on home working days in comparison to office days (7571 vs 9669 steps/day, $p < 0.01$). A sub-sample ($n=39$, 82% female) provided dietary data, revealing that total energy intake was significantly higher on home working days (1732 vs 1554 kcal/day, $p=0.012$). No differences were seen in proportions of macronutrients contributing to total energy intake ($p > 0.05$) across working environments. Snacking behaviours did not differ between environments ($p > 0.05$).

Conclusion: Findings suggest working from home is associated with higher levels of sedentary behaviour, reduced physical activity and increased energy intake. Further work should examine perceived barriers and facilitators to

B. MOTIVATION AND BEHAVIOR CHANGE

increasing movement within the home working environment, with the view of creating tailored behaviour change interventions for this, now common working environment.

II-P-B.27

A Systematic Review and Meta-analysis on Actionable Dietary Behaviours and the Development of Obesity: An OBCT Study

L. Bertoni¹, J. Wertwijn¹, N. Siddiqui¹, K. Almer Bernsdorf Torp², J.W. Beulens¹, J.M Stuber¹

¹Amsterdam UMC, Epidemiology and Data Science, Amsterdam, Netherlands, ²Center for Clinical Research and Prevention, Copenhagen University Hospital, Copenhagen, Denmark

Purpose: Obesity burden is partially driven by dietary behaviours. Young adults are especially vulnerable to weight gain due to life transitions disrupting eating habits (e.g. new family or job). We evaluated longitudinal evidence on actionable dietary behaviours and obesity development in adults.

Methods: The systematic review followed PRISMA 2020 guidelines and was registered in PROSPERO [ID:CRD42024611490]. Prospective cohorts and randomized controlled trials on meal frequency, -timing, -skipping, snacking, portion size, eating speed, cooking skills, mindful eating, shopping habits, social eating, and eating out were included. Studies eligible were conducted in the general population with participants aged 18–65 years at baseline, with a focus on young adults (18–40 years), depending on data availability. The primary outcome was obesity incidence (BMI ≥ 30 kg/m²); secondary outcomes: incidence of overweight (BMI ≥ 25 kg/m²), BMI-, weight-, waist circumference changes. Screening was supported by ASReview, data extraction, synthesis and quality appraisal by Elicit AI. Bias was assessed through Newcastle-Ottawa scale and ROBIS. Random-effects meta-analyses and vote counting based on direction of associations were used for data synthesis.

Results: We included 88 studies: 68 cohorts, 20 RCTs. No studies were found for social eating and shopping habits. Only a few studies per behaviour could be meta-analyzed, and not all behaviours were represented. Examples of results for cohorts: each additional weekly eating-out occasion was associated with a small annual BMI gain (+0.02 kg/m²/year; 95%CI 0.00-0.04; I²=89.1%; 4 cohorts); snacking versus not snacking was associated with higher incident obesity (OR 1.58; 95% CI 0.09–2.56; I²=49%; 2 cohorts); adding one extra eating occasion per day was associated with a small annual weight gain (+0.01 kg/year; 95%CI -0.01-0.02; I²=0.0%; 2 cohorts); and delay in the average time of the first meal was associated with an annual increase in BMI (+0.06 kg/m²/year; 95%CI -0.16-0.29; I²=38.3%; 2 cohorts). Vote counts support these patterns. Results for RCTs will be ready at the time of the conference.

Conclusion: Longitudinal observational evidence suggested that more frequent eating out, snacking, higher meal frequency and delayed meal timing are associated with higher development of obesity; effects are small but may accumulate over time. High heterogeneity requires cautious interpretation.

II-P-B.28

The Associations of Sedentary Behavior and Physical Activity with Musculoskeletal Symptoms in Hybrid Office Workers: A Compositional Data Analysis

I. Parés-Salomón¹, E. Cirera-Viñolas¹, B. Loefer², K.P. Dowd³, A.M. Señé-Mir¹, A. Gustems-Morral¹, I. Luznik⁴, M. Pajek⁴, K.I Proper², A.M Puig-Ribera¹, J. Bort-Roig¹

¹Universitat de Vic - Universitat Central de Catalunya, Sport and Physical Activity Research Group, Vic, Spain, ²National Institute for Public Health and the Environment, Centre for Prevention, Lifestyle and Health, Bilthoven, Netherlands, ³Technological University of the Shannon, SHE Research Centre, Department of Sport and Health Sciences, Athlone, Ireland, ⁴University of Ljubljana, Faculty of Sport, Ljubljana, Slovenia

Purpose: Hybrid work is the new norm for those in desk-based jobs. This modality of work further increases sedentary time, and may subsequently increase the behaviors related effects on health, such as musculoskeletal symptoms. However, little is known about accumulated physical activity (PA) patterns and sedentary behaviors (SB) (and their associations with health) since the adoption of hybrid work after the COVID-19 pandemic. Therefore, the aims of the study are to (i) examine patterns of SB and PA among hybrid office workers, (ii) assess their associations with musculoskeletal symptoms, and (iii) assess the impact of replacing time spent in SB with PA on musculoskeletal symptoms.

B. MOTIVATION AND BEHAVIOR CHANGE

Methods: Hybrid office employees from Ireland, Slovenia, Spain and the Netherlands were enrolled in the study. Self-reported measures assessed musculoskeletal symptoms, along with sociodemographic and home environment. Total, occupational and non-occupational SB, standing, light-intensity PA and moderate-to-vigorous PA (MVPA) were assessed by the activPALTM. A compositional data analysis was employed to investigate the associations between SB and PA patterns and musculoskeletal symptoms. For significantly associated patterns, isotemporal substitution analyses were conducted.

Results: A total of 163 hybrid office workers (71.8% female; median age 39 years) participated in the study. On average, participants sat for 10.95 h/day. Participants accumulated 18 minutes more sitting time while working during home-office work than in the traditional office location ($p < 0.001$). The proportion of sitting time on days of home-office work was associated with musculoskeletal symptoms (OR: 2.75, 95% CI: 1.24, 6.55). Reallocating sitting time with MVPA reduced the predicted probability of experiencing musculoskeletal symptoms at home, with greater reductions observed at higher amounts of substitution.

Conclusion: Sitting time during home-office working days is associated with musculoskeletal symptoms, while replacing it with MVPA is associated with lower odds of such symptoms. These findings support the need for home-office interventions that reduce SB and replace SB with more active breaks of MVPA.

II-P-B.29

Autonomous Motivation Predicts Mental Health without Mediation from Physical Activity or Screen Time

B. da Costa¹, A. Stabelini Neto², B. Law³, B. Bruner³

¹McGill University, Department of Kinesiology and Physical Education, Montreal, Canada, ²Universidade Estadual do Norte do Paraná, Jacarezinho, Brazil, ³Nipissing University, School of Physical and Health Education, North Bay, Canada

Purpose: Increased autonomous motivation for physical activity (PA) is theoretically expected to drive higher participation levels and also lead to decreased sedentary screen time (ST) according to the displacement hypothesis. Both of these behavioural changes are thought to benefit mental health. In this study grounded in Self-Determination Theory, we explored if the association between autonomous motivation for PA and mental health is mediated by time spent on PA and ST.

Methods: We analyzed cross-sectional data from 330 participants (mean age = 18.2 ± 2.0 years; range 14–21). The sample included secondary (33.3%) and university (59.7%) students, with 55.2% identifying as male. PA volume was measured using an adapted version of the Self-Administered Physical Activity Checklist, and ST were assessed using an adapted Questionnaire for the Screen Time of Adolescents. Motivation for PA was assessed using an adapted version of the Behavioural Regulation in Exercise Questionnaire (BREQ-3) to calculate the Relative Autonomy Index, and mental health was measured using the Mental Health Inventory-5. We fit a parallel mediation model where motivation predicted mental health both directly and indirectly through PA volume and a latent ST factor (combining video watching, gaming, and social media time).

Results: The parallel mediation model demonstrated adequate fit to the data (CFI=0.973; SRMR=0.035; RMSEA=0.071). Autonomous motivation predicted both PA volume ($b=0.33$, $p < .001$) and ST ($b=0.46$, $p < .001$). However, neither PA volume ($b=-0.04$, $p=.528$) nor ST ($b=0.09$, $p=.183$) significantly predicted mental health scores. Consequently, the indirect effects through PA ($p=.530$) and ST ($p=.190$) were non-significant. The only significant predictor of mental health was the direct path from autonomous motivation ($b=0.37$, $p < .001$).

Conclusion: The volume of PA and ST did not explain the relationship between motivation for PA and mental health. These findings suggest that the mental health benefits often attributed to lifestyle behaviours may be driven more by the underlying autonomous motivation than by the volume of the behaviour itself. Interventions targeting mental health in youth should prioritize autonomous motivation over simply prescribing behavioural targets.

II-P-B.30

Exploring Professionals' Perspectives on Healthcare and Lifestyle Coaching Experiences for People with a Migration Background: A Qualitative Study

T. Hoekstra¹, J. Stufkens¹, M. Fluit², D. Jansen², F. Hoekstra³

¹Vrije Universiteit Amsterdam, Amsterdam, Netherlands, ²Stichting Special Heroes, Utrecht, Netherlands, ³University of British Columbia, Kelowna, Canada

B. MOTIVATION AND BEHAVIOR CHANGE

Purpose: This study aims to explore the experiences and perceptions of professionals in health and lifestyle coaching for people with a migration background to inform the development and scale-up of the lifestyle coaching service *Healthy Habits Coaching (HHC)*. HHC stands out by specifically targeting individuals with chronic conditions and/or physical disabilities. This inclusive approach recognizes the unique challenges people with chronic conditions and/or physical disabilities face in adopting a healthy lifestyle. HHC provides free online or phone coaching, facilitated by volunteers who bring both personal experiences as peers and professionals' expertise as lifestyle coaches. Their aim is to motivate individuals to develop and maintain healthy habits across multiple lifestyle domains, including physical activity, nutrition, sleep, and relaxation.

Methods: This qualitative study was conducted in partnership with a Dutch community organization (Stichting Special Heroes) using a pragmatic approach. Semi-structured interviews were conducted with professionals (n=11) with professional experiences in migration, diversity and/or health (e.g., lifestyle coaches, academics, policy makers). The data were analysed using a reflexive thematic approach.

Results: We identified three main themes. The first theme described the *participants' perceptions of the impact of cultural background on the experiences in healthcare and lifestyle coaching*. The second theme focused on *recognition as key aspect to promote effective communication and understanding between lifestyle coach and client*. The third theme emphasized the *need for integrating diversity into lifestyle coaching programs to ensure accessibility, availability, and awareness among people with a migration background*.

Conclusion: The findings of this study emphasizes the importance of cultural competence and recognition of diverse identities among lifestyle coaches, with the need for inclusive strategies to effectively reach and engage people with a migration background in lifestyle coaching. The insights of this study will be used to inform the optimization and implementation of Healthy Habits Coaching program and, subsequently contribute to improving inclusive lifestyle coaching services for people with a migration background.

II-P-B.31

Long-term Effect of a Person-centred Lifestyle Intervention on Cancer-related Fatigue and Lifestyle Behaviour Change: Six-month Follow-up after a Randomized Controlled Trial

L. Schepers¹, A.J. Verkaar¹, J. de Vries-ten Have¹, S. Bloemhof¹, E. Kampman¹, L.H. Winkens¹, R.M. Winkels¹

¹Wageningen University & Research, Wageningen, Netherlands

Purpose: We previously reported that a six-month lifestyle intervention improved diet and physical activity but did not reduce cancer-related fatigue among colorectal cancer (CRC) survivors. This follow-up study examined the long-term effect of the intervention on cancer-related fatigue and the maintenance of lifestyle behaviour changes six months after study completion.

Methods: 161 stage I-III CRC survivors who were experiencing cancer-related fatigue, were randomized to the intervention group (n=80), receiving six months of lifestyle coaching to improve adherence to the World Cancer Research Fund (WCRF/AICR) dietary and physical activity guidelines, or to the control group (n=81), receiving usual care. Data were collected at baseline and six months as part of the original trial, and six months beyond completion of the trial for this long-term follow-up study. Data on diet, physical activity and cancer-related fatigue were assessed with questionnaires.

Results: During the six months of the randomized controlled trial, there were favourable changes in dietary behaviours and physical activity in the intervention group; the control group did not show changes to the same extent. Six months beyond completion of the randomized trial, changes in diet quality appeared to be largely maintained in the intervention group, while physical activity declined in both groups. Six months beyond completion, cancer-related fatigue did not significantly differ between the intervention and control groups (1.5, 95% CI: -1.4, 4.3).

Sensitivity analyses were conducted including only those participants of the intervention group who implemented the largest improvements in diet and/or physical activity and only those participants of the control group who did not implement changes in diet and/or physical activity over the total 12 months of follow-up. Across those sensitivity analyses, reductions in cancer-related fatigue consistently favoured the intervention group.

Conclusion: The intervention did not result in long-term effects on cancer-related fatigue. Nevertheless, our sensitivity analyses may putatively suggest that larger changes in diet and or physical activity are needed to exert an effect on cancer-related fatigue.

B. MOTIVATION AND BEHAVIOR CHANGE

II-P-B.32

Effects of a Combined Self-management and Exercise Intervention on Sedentary Time and Patterns in Community-dwelling Older Adults: A Randomized Controlled Trial

V.R. Santos¹, G. Cassemilano¹, A.C. Farche¹, S. Lee¹, L. Message¹, P. Rossi¹, G. Oviedo², M. Guerra-Balic³, M. Giné-Garriga³, A. Takahashi¹

¹Federal University of São Carlos, Department of Physical Therapy, São Carlos, Brazil, ²Mississippi State University, Department of Kinesiology, Starkville, United States, ³Blanquerna - Ramon Llull University, School of Psychology, Education and Sport Sciences, Barcelona, Spain

Purpose: The aim of this study was to assess the effectiveness of adding self-management strategies (SMS) to reduce sedentary behavior (SB) to a multicomponent exercise (ME) program, compared with the exercise program alone, in reducing sedentary time (ST) and modifying SB patterns among community-dwelling older adults.

Methods: In this randomized, blinded clinical trial, 46 community-dwelling older adults were assigned to an intervention group (IG= 23) receiving ME plus SMS to reduce SB, or to a control group (CG= 23) receiving exercise alone. Both groups participated in the ME program for 40 weeks, while SMS to reduce SB were delivered only to the IG during the first 16 weeks. ST and SB patterns (number of sedentary bouts >30 minutes and >60 minutes) were assessed using the activPAL3 micro accelerometer at baseline, 16 weeks, and 40 weeks (24-week follow-up after SMS withdrawal). Intervention effects were analyzed using generalized linear mixed models.

Results: Participants had a mean age of 73.5 ± 6.7 years, and 73.9% were female. Both groups significantly reduced ST after 16 weeks (difference= -0.95 hours; 95%CI= -1.37 to -0.52 ; $p < 0.001$), but values returned to baseline levels at 40 weeks. The IG reduced ST from 8.56 (0.60) hours to 7.53 (0.60) hours after 16 weeks, returning to 8.59 (0.62) hours at 40 weeks. Similarly, the CG reduced ST from 9.41 [0.62] hours to 8.55 (0.63) hours after 16 weeks, increasing to 8.86 (0.64) hours at 40 weeks. We also observed that the IG was not superior to the CG in reducing ST or the number of sedentary bouts >30 minutes and >60 minutes at either 16 or 40 weeks ($p > 0.05$).

Conclusion: The addition of SMS to reduce SB for 16 weeks was not superior to a ME program alone in reducing ST or modifying SB patterns in community-dwelling older adults. Although short-term reductions were observed, effects were not sustained at follow-up, suggesting that longer or more intensive behavioral components may be needed. Further studies should explore alternative approaches, contexts, and extended intervention periods.

II-P-B.33

Precision Emotion and Affective Context (PEAC) Process Model: A Theoretical Framework for Creating the Affective Circumstances that Promote Engagement

S.M. Carpenter¹, N. Roberts²

¹Arizona State University, College of Health Solutions, Tempe, United States, ²Arizona State University, School of Social and Behavioral Sciences, Tempe, United States

Purpose: Behavior change interventions are key to improving health and well-being. Existing models of behavior change, however, often overlook the importance of dynamic affective states. We propose the “precision emotion and affective context (PEAC) process model of engagement for behavior change” as a theoretical framework to advance our understanding of how affect drives engagement and subsequent behavior.

Methods: We integrate extant literatures on affective science, engagement, and behavior change to develop a novel theoretical model that highlights the importance of accounting for affective circumstances when designing and implementing behavior change interventions, including those promoting physical activity. PEAC accounts for affect that is both incidental and integral to the intervention: ongoing affective states that may work for or against the likelihood of engaging with the intervention (incidental), and affective states that are elicited by the intervention and consequently shape behavior change (integral). We emphasize the importance of moderate levels of arousal and positive affective states, along with the need for contextual congruence, social acceptability, and personally meaningful approaches, to sustain engagement and promote behavior change.

Results: The PEAC model is illustrated through dynamic valence and arousal processes guiding real-time engagement in interventions intended to promote every day physical activity. For instance, an individual enrolled in a digital physical activity intervention experiencing a high arousal state may not notice the intervention prompt, may perceive

B. MOTIVATION AND BEHAVIOR CHANGE

the intervention as distracting, and/or feel too overwhelmed to engage. While in a low arousal state they may lack motivation to read the prompt or lack energy to engage in the behavior (e.g., go for a walk). Negative affect (e.g., anxiety about an upcoming appointment) may lead to ignoring the prompt or increased anxiety (e.g., reminder to exercise). However, when experiencing a positive, moderate arousal state, a prompt suggesting a brief walk is likely to capture attention, generate more positive affect, and promote engagement in the intended behavior.

Conclusion: PEAC advances our understanding of the relationship between affect and behavior change by providing novel and testable predictions for how to construct and harness the affective circumstances necessary to promote sustained intervention engagement.

II-P-B.35

Barriers, Motivators and Response to the First 10 Weeks of a Physical Activity Intervention in Patients with Heart Failure: Preliminary Analyses from the STEP-IN Trial

A.I. Manzano-Salcedo¹, S. Vidal-Almela¹, E.J. Barranco-Moreno¹, J.H. Migueles¹, A.M. García-Segura¹, S. Moreno-Galiano¹, M. Cobo-Gutierrez¹, M. Rodríguez-Elert¹, J.G. Sánchez-Ramos^{2,3}, S. López-Fernández^{3,4}, F.M. Rodríguez-Santiago⁵, L. Torres-Quintero⁴, R. García-Orta^{3,4}, E. Moreno-Escobar^{2,3}, F.B. Ortega^{1,6}

¹University of Granada, Department of Physical and Sports Education, Sport and Health University Research Institute (iMUDS), Faculty of Sport Sciences, Granada, Spain, ²San Cecilio Clinical University Hospital, Cardiology Service, Granada, Spain, ³Instituto de Investigación Biosanitaria, ibs.Granada, Granada, Spain, ⁴Virgen de las Nieves University Hospital, Cardiology Service, Granada, Spain, ⁵San Cecilio Clinical University Hospital, Inter-hospital Cardiology Unit, Granada, Spain, ⁶Instituto de Salud Carlos III, CIBER de Fisiopatología de la Obesidad y Nutrición (CIBEROBN), Madrid, Spain

Purpose: Despite the benefits of physical activity to manage heart failure, adherence to structured exercise programs remains low, highlighting the need for accessible and scalable alternatives. The aim was to describe: (i) participant-reported barriers and facilitators to be more active; (ii) preliminary changes in daily steps during the first 10 weeks of intervention in participants of the STEP-IN trial.

Methods: STEP-IN is a 9-month randomized controlled trial in patients with heart failure (ejection fraction <50%) and NYHA class II-III. Intervention participants are remotely monitored and receive individualized daily step goals every two weeks. The first 3 months target steps/day and from month 4 step cadence is introduced. To promote behaviour change, the intervention incorporates: wearable self-monitoring (Fitbit Inspire 3); graded goal setting; visual feedback (HealthyChronos platform); personalized WhatsApp prompts; motivational badges; and 3 face-to-face coaching sessions. Barriers and motivators were assessed at the first coaching session using a questionnaire. An exploratory paired t-test compared baseline with week 10.

Results: Nine participants (66.7 years [± 8.8]; 55.6% male; 66.7% HFrEF; 88.9% NYHA class II) who had completed the first 10 weeks of the intervention were included. The most frequently endorsed barriers were: concerns that the heart may not tolerate activity (44.4%); physical condition/comorbidities limiting movement (44.4%); fear when their heart beats fast (33.3%) and lack of a safe environment or favourable weather to walk (33.3%). The most common motivators were to: improve energy and reduce fatigue (100%); reduce joint discomfort (88.9%) and maintain independence (88.9%).

Mean steps/day increased from 9,609 ($\pm 5,128$) at baseline to 11,933 ($\pm 5,710$) at week 10 (mean change, +2,324 [$\pm 2,904$]; 95% CI; t-test $p=0.043$). Seven participants (77 increased $\geq 1,000$ steps/day and 66.7% achieved at least half of prescribed step goals (≥ 2 of 4).

Conclusion: Early STEP-IN data indicate symptom-related concerns and comorbidities as common constraints, whereas reduced fatigue/joint discomfort and maintaining independence are key motivators. These analyses show a relevant increment in daily steps during these first weeks, but full-sample analyses will assess effectiveness of this trial.

II-P-B.36

Understanding Student Motivation to Participate in GutGirl (GUT Health and GIRL Fitness): A Physical Activity-microbiome Intervention Study among Female University Students

B. MOTIVATION AND BEHAVIOR CHANGE

F. Salonna¹, A. Buková¹, Z. Küchelová¹, P. Berta¹, D. Kaško¹, P. Melicharová¹, M. Ryniková², V. Demečková²

¹PJ Šafárik University, Institute of Physical Education and Sport, Košice, Slovakia, ²PJ Šafárik University in Košice, Faculty of Science, Institute of Biology and Ecology, Košice, Slovakia

Purpose:

Understanding what motivates female university students to engage in research-based interventions is important for improving recruitment and retention in health studies. This is particularly relevant for gut microbiome research, where sustained adherence to physical activity protocols is essential. This study explored incentives that motivated female undergraduate students to participate in GutGirl, a RCT examining links between physical activity and the gut microbiome. The intervention ran from September to December 2025 and included two experimental and one control groups, combining endurance and endurance–strength training. To inform recruitment and the preparatory phase, we conducted a preliminary survey to assess interest and identify key motivational factors influencing participation.

Methods: A cross-sectional survey was conducted among 391 Slovak female undergraduate students to identify motivational factors for participating in an intervention on physical activity and the gut microbiome. The questionnaire was developed based on a focus group discussion with experts and included items on willingness to participate and perceived incentives. Participants were recruited during physical activity classes and completed the survey online. Participation was voluntary and anonymous. Only complete responses were analyzed using descriptive statistics.

Results: A total of 391 responses were collected, of which 241 were valid. Of these, 9% [A1] expressed definite willingness to participate, 17% probable willingness, and 37% were undecided. The strongest motivating factors were academic credit for physical education (65%), access to a free comprehensive fitness assessment (59%), the opportunity to improve personal health (59%), and an individualized training plan (53%). Financial incentives (36%), participation certificates (40%), and free gym membership (36%) were rated as less important.

Conclusion: Our findings highlight that intrinsic and academically aligned incentives are more effective motivators than purely material or symbolic rewards. This suggests that for young adult populations, particularly female university students, the perceived educational and health-related value of participation outweighs short-term financial gain. Understanding these preferences is essential not only for the successful implementation of the intervention but also for informing strategies to recruit and engage participants in health and exercise science research. Tailoring recruitment efforts to emphasize academic credit, personalized feedback, and health improvement may enhance enrollment and adherence in similar intervention studies.

II-P-B.37

Motivation Matters: Predicting Multiple Healthy Lifestyle Behaviors in a Longitudinal Study

E. Wiedemann¹, S. Fiedler¹

¹Vienna University of Economics and Business, Vienna, Austria

Purpose: The adoption of healthy lifestyle behaviors is essential for long-term health and disease prevention, yet engagement varies widely across individuals. Motivational processes play a central role in how health-related behaviors are evaluated, initiated, and maintained. In this study, we examined how key constructs from self-determination theory, social cognitive theory, and the transtheoretical model of behavior change relate to healthy lifestyle behaviors.

Methods: We conducted a pre-registered longitudinal study in Austria using a nationally representative sample. In Wave 1 (N = 1,321), we tested cross-sectional associations between self-determined motivation, basic psychological need satisfaction, self-efficacy, knowledge of health guidelines, social network size, and multiple health behaviors. Fifty-six percent of participants from Wave 1 completed Wave 2 five months later (N = 744). Motivational readiness for health behavior change was reassessed to test whether stage-standardized self-efficacy and decisional balance at T1 predicted positive health behavior at T2 (i.e., progression to the next stage of behavioral change or maintenance of positive health behaviors).

Results: Cross-sectionally, self-determined motivation and basic psychological need satisfaction were associated with higher levels of physical activity and fruit and vegetable consumption. Self-efficacy was positively associated with physical activity and fruit and vegetable consumption and negatively associated with tobacco and nicotine consumption and alcohol intake. Knowledge of health guidelines was not a consistent predictor of health behavior when motivational factors were included in the analyses. Longitudinally, both self-efficacy and decisional balance predicted positive health behavior in physical activity, but not fruit and vegetable consumption. Self-efficacy additionally predicted positive health behavior in tobacco and nicotine consumption and alcohol intake. Decisional

B. MOTIVATION AND BEHAVIOR CHANGE

balance was not assessed for these behaviors.

Conclusion: Overall, the findings highlight motivational processes as key cognitive mechanisms underlying healthy lifestyle behaviors, suggesting that interventions should prioritize strengthening motivation in addition to providing health information. Longitudinal results further indicate that behavior-change mechanisms may differ across health behaviors, underscoring the importance of tailoring interventions to specific behavioral targets. Together, these findings highlight the central role of motivational processes in health behavior and suggest that integrating constructs across health behavior theories may improve our understanding of how healthy lifestyle changes emerge and are sustained.

II-P-B.38

Healthy Eating Research to Overcome Barriers and Empower with Strategies to Improve Health Equity in SCI (HEROES - SCI)

A. Deierlein¹, S. Nandy¹, R. Chen², S. Park³, A. Trude²

¹New York University, School of Global Public Health, New York, United States, ²New York University, Steinhardt School, New York, United States, ³Florida State University, School of Communication, Tallahassee, United States

Purpose: Adults living with SCI do not meet dietary recommendations and face numerous nutrition-related challenges that adversely impact their health and well-being. These challenges include physiological changes that exacerbate development of chronic conditions, such as obesity, as well as physical changes that inhibit their ability to make healthy food choices, such as support for food shopping and preparation. This pilot study aims to integrate quantitative and qualitative data to identify and understand barriers and facilitators of healthy eating among adults with SCI. This information will be used to co-design an intervention to improve dietary intakes among adults with SCI in real-life settings.

Methods: We are collecting surveys and dietary assessments from 150 adults (18+ years) living with SCI in the U.S. Surveys query information on participants' sociodemographic characteristics, health conditions, health behaviors, and food environment, and include a Theoretical Domains Framework (TDF) self-evaluation of barriers and facilitators of healthy eating. The self-administered Vioscreen food frequency questionnaire, with 155 food and beverage items, collects usual dietary intakes during the previous three months. Following quantitative data collection, we will conduct one-on-one, semi-structured in-depth interviews with 15 participants with SCI, 15 family member/caregivers, and 10 key informants within in the SCI community. Interviews with participants with SCI will incorporate photo-elicitation.

Results: To-date, we have 122 completed surveys and dietary assessments. The mean (SD) age of participants is 49.0 (15.3) years, half are female (49.5%), and 74.7% identify as non-Hispanic White. Nearly a third (31.9%) report being at risk for food insecurity, 16.5% describe their diet as unhealthy, 40.7% have never received nutrition counseling, and 58.3% are dissatisfied with their body. On the TDF self-evaluation, the following domains emerged for further probing during qualitative data collection: skills; identity; beliefs and capabilities; optimism; memory, attention, and decision process; social influences; emotion; and behavioral regulation.

Conclusion: We will present formal analyses of the survey and dietary assessment at the conference, providing an explanation of the development of the TDF self-evaluation. We will also present next steps for this pilot research.

II-P-B.39

From Access to Action: Testing Self-determination Theory Mechanisms Linking Perceived Facility Access to Recreational Physical Activity

M.J. Almeida¹, J. Ribeiro²

¹University of Porto/Faculty of Sport, CIFI2D, Porto, Portugal, ²Polytechnic Institute of Bragança/School of Education, Bragança, Portugal

Purpose: Recreational physical activity (RPA) is discretionary and self-initiated, yet socio-ecological research rarely examines how perceived environmental access relates to RPA through motivational processes. Guided by Self-Determination Theory (SDT), this study examined pathways linking perceived access to exercise facilities with RPA in adults. Specifically, we tested whether perceived access was indirectly associated with RPA through basic psychological need satisfaction (BPNs) and motivational regulations, and whether competence, autonomy, and relatedness differed in their explanatory role.

B. MOTIVATION AND BEHAVIOR CHANGE

Methods: A cross-sectional survey was conducted among Portuguese adults aged 18–65 years (N = 916). Participants reported perceived access to exercise facilities, basic psychological need satisfaction for RPA (competence, autonomy, relatedness), motivational regulations (autonomous, controlled, amotivation), and RPA derived from the recreational domain of the Global Physical Activity Questionnaire. Models adjusted for age, sex, socioeconomic status, and population density. Hierarchical linear regressions examined incremental variance explained (covariates → access → needs → motivation). Need-differentiated models estimated unique associations of competence, autonomy, and relatedness. SDT-consistent indirect associations were tested using bootstrapping, with HC3 robust standard errors as a sensitivity analysis.

Results: Regression models explained substantial variance in RPA. Adding perceived access increased explained variance modestly ($\Delta R^2 = 0.014$), whereas adding need satisfaction produced a large increment ($\Delta R^2 = 0.320$); adding motivational regulations further improved prediction ($\Delta R^2 = 0.039$). In need-differentiated models, competence was the strongest unique correlate of RPA ($\beta = 0.470$, $p < .001$), autonomy was smaller ($\beta = 0.131$, $p = .050$), and relatedness was not significant ($\beta = 0.000$, $p = .994$). In the full SDT model, competence ($\beta = 0.357$, $p < .001$; HC3 95% CI [0.226, 0.488]) and autonomous motivation ($\beta = 0.306$, $p < .001$; HC3 95% CI [0.185, 0.426]) remained positively associated with RPA. Indirect effects were consistent with an access–need satisfaction–autonomous motivation pathway (standardised indirect $\beta = 0.070$, 95% CI [0.040, 0.100]). No moderation by socioeconomic status or population density was observed.

Conclusion: For discretionary RPA, perceived facility access relates to behaviour primarily through competence satisfaction and autonomous motivation. These findings extend SDT-informed research by clarifying motivational pathways through which environmental perceptions relate to recreational physical activity.

C. CANCER PREVENTION AND MANAGEMENT

I-P-C.02

Cardiorespiratory Fitness and Physical Activity with Cognitive Changes in Women with Breast Cancer Undergoing Chemotherapy: A Prospective Match-control Study

S. Addetia¹, E. Warner², C. Sabiston¹, J. Ryan^{3,1}, H. Xiao¹, G. Ghazinour¹, S. O'Rourke¹, L. Trinh¹

¹University of Toronto, Toronto, Canada, ²Sunnybrook Health Sciences Centre, Toronto, Canada, ³Rotman Research Institute, Toronto, Canada

Purpose: Breast cancer (BC) patients who have undergone adjuvant chemotherapy are at high risk for cancer-related cognitive impairment (CRCI). The primary study objective was to characterize longitudinal changes in cognitive function and between-group differences between BC patients receiving chemotherapy and age-matched, healthy controls. Secondary objectives examined cross-sectional associations of cardiorespiratory fitness (CRF) and moderate-to-vigorous physical activity (MVPA) with cognitive function.

Methods: A prospective cohort study included 55 women (n = 32 stage I – III BC; n = 23 age-matched controls) from baseline (pre-chemotherapy) to follow-up (5 months post-chemotherapy). Participants were recruited via BC clinics at the Odette Cancer Centre (patients) and the community (controls). Cognitive function was assessed remotely using the NIH Toolbox Cognition Battery v2. CRF was assessed using the six-minute walk test and MVPA was objectively assessed using GT3X+ ActiGraph accelerometers. Analyses in Stata 17 used longitudinal mixed-effects models, entering CRF and MVPA separately and adjusting for anxiety and depression.

Results: Most participants were White (BC = 53%; controls = 65%), married/partnered (BC = 69%; controls = 74%), and highly educated (>90%). In CRF-adjusted models, Picture Sequence Memory improved from baseline to follow-up ($\beta = 4.92$, 95% CI [0.91, 8.92], $p = 0.016$) and higher CRF showed a small improvement List Sorting ($\beta = 0.02$, 95% CI [-0.00, 0.03], $p = 0.059$) in both groups. Oral Reading Recognition ($\beta = -5.60$, 95% CI [-11.33, 0.12], $p = 0.055$) and Auditory Verbal Learning ($\beta = -2.99$, 95% CI [-6.05, 0.07], $p = 0.055$) were lower among BC patients. No significant group x time interactions were observed.

In MVPA-adjusted models, there was a small, non-significant improvement in both groups ($\beta = 4.01$, 95% CI [-0.23, 8.25], $p = 0.064$), with no significant group x time interaction ($p = 0.998$). BC patients scored lower on Oral Reading Recognition ($\beta = -8.31$, 95% CI [-14.24, -2.38], $p = 0.006$) and Auditory Verbal Learning ($\beta = -3.96$, 95% CI [-7.07, -0.86], $p = 0.012$).

Conclusion: CRF and MVPA may modestly influence cognitive outcomes after breast cancer treatment, and thus should be important targets for CRCI interventions.

I-P-C.03

Integrating Artificial Intelligence in Personalized Biofeedback Messaging: Implications for Future mHealth Behavioral Interventions

A. On¹, G.E. Brannon², M. Titly¹, A. Chalise¹, V. Patel¹, K.-Y. Chang¹, S. Wang³, Y. Liao¹

¹University of Texas at Arlington, Department of Kinesiology, Arlington, United States, ²University of Texas at Arlington, Department of Communication, Arlington, United States, ³University of Texas at Arlington, Department of Industrial, Manufacturing, and Systems Engineering, Arlington, United States

Purpose: Physical activity (PA) can reduce mortality in survivors of several cancers. One key behavioral change strategy in PA interventions is performance feedback. Combining wearable sensors that continuously monitor biological data (e.g., activity, sleep, glucose) with artificial intelligence (AI) provides opportunities to further develop and deliver personalized biofeedback. This study assessed the acceptability of a remotely delivered physical activity intervention using personalized text messages based on wearable sensor data. Specifically, we examined how artificial intelligence (AI) could be used to support such interventions moving forward.

Methods: Thirteen insufficiently active adult cancer survivors who completed primary treatment at least three months prior to enrollment and had a smartphone with daily internet access participated in individual interviews at the conclusion of their 12-week intervention periods (October 2024-August 2025). Participants discussed their previous AI tool usage, feelings about using AI technologies in analyzing and interpreting health-related data, concerns about using AI-generated health information, and compared AI health information with online and healthcare provider sources. Coders transcribed and analyzed a total of 363 pages using Braun and Clarke's thematic analysis method.

Results: Participants had a mean age of 57 (SD±12; ranged 23-73), and were predominantly women (92.3%), White

C. CANCER PREVENTION AND MANAGEMENT

(76.9%), and non-Hispanic (76.9%). Most participants had a bachelor's degree or higher (76.9%) and had an income of \$75,000+ (61.5%). The average digital health literacy score was 33.6 out of 40 (SD±6.2; ranged 21-40). Over half of the participants used AI tools in their daily lives. There were mixed results in the perceived accuracy of AI-facilitated health information, with some saying that AI information would be the least accurate, and others saying it would be the most accurate. While some concerns related to trust were identified, nearly half of the participants said they had no concerns about AI using and interpreting their health-related data. Participants highlighted that the AI-produced data could help facilitate conversations with their healthcare provider.

Conclusion: AI has the potential to augment personalized feedback messaging for physical activity interventions and is perceived positively by participants of such health interventions. AI-produced biofeedback messaging among cancer survivors should be prioritized to reduce mortality among cancer survivors.

I-P-C.04

Lifestyle and Dietary Inflammation Scores and Risks of Recurrence and Progression among Patients with Non-muscle Invasive Bladder Cancer

J. Kiebach¹, C. Kamps², E. Wesselink³, K.KH Aben^{1,4}, A.G van der Heijden⁵, F.JB van Duijnhoven⁶, L.ALM Kiemeny^{1,5}, A. Vrieling^{1,2}

¹Radboud University Medical Center, IQ Health Science Department, Nijmegen, Netherlands, ²Radboud University Medical Center, Department of Primary and Community Care, Nijmegen, Netherlands, ³The Netherlands Cancer Institute - Antoni van Leeuwenhoek Hospital, Division of Molecular Pathology, Amsterdam, Netherlands, ⁴Netherlands Comprehensive Cancer Organisation, Department of Research and Development, Utrecht, Netherlands, ⁵Radboud University Medical Center, Department of Urology, Nijmegen, Netherlands, ⁶Wageningen University & Research, Division of Human Nutrition and Health, Wageningen, Netherlands

Purpose: A healthy lifestyle and diet may improve outcomes among patients with non-muscle invasive bladder cancer (NMIBC), possibly by reducing systemic inflammation. Yet, this relationship has not been explored using large cohorts and validated scores. Therefore, this study investigated the association of an inflammation biomarker panel-weighted Lifestyle (LIS) and Dietary Inflammation Score (DIS) after diagnosis with the risks of recurrence and progression in patients with NMIBC, and performed a secondary analysis of high-sensitivity C-reactive protein (hsCRP) in relation to these outcomes.

Methods: Patients with newly diagnosed NMIBC between 2014 and 2021 were recruited for the prospective multi-center cohort UroLife. Self-reported information about lifestyle (n=1,334) and/or diet (n=1,306) were collected at 3 months after diagnosis using lifestyle and Food Frequency Questionnaires. The LIS and DIS were calculated to capture the inflammatory potential of lifestyle and diet, with higher scores reflecting more pro-inflammatory exposures. Plasma hsCRP was measured at 3 months after diagnosis, and log₂-transformed for the analyses. The association of LIS and DIS with hsCRP was ascertained in multivariable linear regression models. The association of the LIS and DIS, as well as hsCRP, with the risks of first or multiple recurrence(s), and stage and/or grade progression was assessed using multivariable Cox proportional hazards models.

Results: Over a median follow-up time of 4.7 years, 466 patients had at least one recurrence, and 155 had progression. Each 1-point increment in LIS and DIS was associated with a 43% (95%CI 28-53%) and 6% (95%CI 3-10%) increase in hsCRP, respectively. Higher LIS and DIS were not associated with the risks of first recurrence, multiple recurrences, and progression. However, a 1-point increase in DIS, i.e. a more pro-inflammatory diet, showed a non-significant linear trend of a higher recurrence risk (HR 1.02, 95%CI 0.98, 1.07). There was no association between hsCRP and risks of first or multiple recurrence(s), or progression.

Conclusion: A pro-inflammatory lifestyle and diet, and systemic inflammation, were not associated with the risks of NMIBC recurrence and progression. Regardless, adopting or maintaining a healthy lifestyle after diagnosis remains critical for overall health, and future research should explore further how inflammatory pathways may contribute to NMIBC prognosis.

C. CANCER PREVENTION AND MANAGEMENT

I-P-C.05

The Perceptions of a Home-based Blood Flow Restriction Training Program during and after Treatment for Hepatopancreatobiliary Cancer

P. Anandavadivelan¹, M. Backman², M. Kotte¹, B. Sunde³, T. Raastad⁴, S. Mijwel¹

¹Karolinska Institutet, Department of Neurobiology, Care Sciences and Society, Stockholm, Sweden, ²Karolinska University Hospital, Molecular Medicine and Surgery, Stockholm, Sweden, ³Karolinska Institutet/Karolinska University Hospital, Department of Clinical Science, Intervention and Technology, Stockholm, Sweden, ⁴Norwegian School of Sports Science, Department of Physical Performance, Oslo, Norway

Purpose: Blood-flow restricted resistance training (BFR-T), which relies on low training loads, may support faster muscle recovery by minimizing the mechanical stress typically linked to heavy-load resistance exercise. When implemented in a home-based setting, it could improve exercise accessibility for cancer survivors; however, research exploring their perspectives remains scarce. This study aims to qualitatively investigate participant's perspectives of a home-based BFR-T training program, specifically identifying barriers and facilitators to participation and adherence, as well as experiences related to the use of an activity tracker and protein supplementation during the intervention.

Methods: Individual interviews with a total of 9 participants were conducted between October to November 2024. These individuals had participated in a two-armed randomised controlled trial that investigated whether BFR-T could prevent or slow down the loss of skeletal muscle mass and enhance the functional capacity and mental health of patients with pancreatic, biliary tract, and liver cancer. The semi-structured discussions were transcribed verbatim and analyzed using reflexive thematic analysis with an inductive approach.

Results: A total of 142 codes were generated as part of the reflexive thematic analysis that were grouped into 4 initial themes summarizing participation and adherence, prior knowledge and experience of exercise benefits, experiences with BFR-T and additional components of the intervention. The analysis with the final themes will be completed by December 2025.

Conclusion: We anticipate that this study will offer valuable and novel insights into experiences, barriers, motivators, and patient preferences regarding BFR-T. Identifying key factors that influence exercise engagement in the context of a relatively new modality such as remote BFR-T is crucial for designing and implementing interventions that ensure accessible, integrated exercise to optimize post-treatment well-being for cancer survivors.

I-P-C.06

Improvements in Strength Following a 12-week Structured Exercise Programme for Post-treatment Adult Cancer Survivors: A Secondary Data Analysis from the Battle Cancer Program

S. Costa¹, C. Bradbury¹, C. Leedham¹, M. Morris¹, A. Gould², C. Robertson², M. Spooner², E. Stamp¹

¹Loughborough University, School of Sport, Exercise and Health Sciences, Loughborough University, United Kingdom,

²Battle Cancer Program, Exeter, United Kingdom

Purpose: Strength is a key component of fitness, underpinning overall health and function of cancer survivors. Structured exercise improves clinical, functional, and survival outcomes in these individuals, but little research has assessed the potential effects of individualised programmes run by trained coaches in community fitness centres/gymnasiums. This study assessed strength changes after the structured Battle Cancer Program, and whether % change differed by cancer type or treatment.

Methods: Secondary data analysis of 142 cancer survivors (80% women; mean age=49.3 years) who completed the 12-week Battle Cancer exercise programme (<https://www.battlecancer.com/>), and had complete data on the strength tests, demographic and cancer-related information. The programme included two 1-hour supervised sessions/week of resistance, aerobic and conditioning exercises, adapted to participants' initial fitness level. Strength measurements included left/right handgrip 1 maximum repetition tests, and back squat, deadlift, and strict press 3 maximum repetition tests (kg), undertaken by trained coaches at the start (pre-) and end (post-) of the programme. Participants reported demographic, cancer type and treatment information via a survey. Cancer type was categorised as breast cancer (64.8%), haematological malignancies (12.7%), central (10.6%) or peripheral (12%) solid tumours. Differences between pre- and post-programme strength measures were calculated (in kg and % from initial measurement), and significance of change was tested with Wilcoxon signed-rank tests. Multiple linear regressions assessed whether cancer type or treatment predicted % change for each strength outcome, controlling for sex and age.

C. CANCER PREVENTION AND MANAGEMENT

Results: All strength measures increased significantly ($p < 0.001$), and % change was not predicted by cancer type or treatment (all $p > 0.07$). Back squat, deadlift, and strict press showed the greatest improvements (median: +12.5kg (42.9%), +17.5kg (42.3%), and +5.0kg (25.0%), respectively) and no loss of strength was recorded. Median change in grip strength was slightly larger for the right than the left hand (+0.9kg (3.08%) vs. +0.8kg (2.79%)), but about one third of participants showed decreases (-0.26.1% to -0.3%).

Conclusion: Results suggest that a supervised 12-week structured exercise programme in community fitness centres significantly improves adult cancer survivors' strength, independently of cancer type and treatment. Further research is needed with a larger, more diverse cohort, and comparing gains with a control group to establish causality.

I-P-C.07

Understanding Physical Activity Behaviors in Immigrant Middle-age Central-American Men with Overweight or Obesity to Inform an Intervention to Reduce Cancer Risk: A Concept Mapping Study

K.R. Lora¹, A.J. Vissek¹, T. O'Neal¹, J. Charter-Harris¹

¹The George Washington University, Exercise and Nutrition Science, Washington DC, United States

Purpose: Cancer is the second-leading cause of death among Hispanics in the U.S. Physical activity (PA) is linked to lower cancer risk. Understanding the PAs Hispanic men engage in and the frequency of such activities is an important step toward the development of culturally appropriate health promotion interventions. This research aimed to engage Central American men with overweight/obesity in mixed-method concept mapping to develop a conceptual framework of the healthy PA activities they engage in and explore the frequency of those behaviors by sociodemographic characteristics.

Methods: 130 Central American men aged 45-64 years living in the Washington D.C metropolitan area completed one or more of the following activities: (a) brainstorming in response to, "Something healthy I do related to PA is..."; (b) sorting of ideas; and (c) rating the frequency they engaged in each PA behavior from 1 (0 times/week) to 5 (6-7 times/week). Similarity matrices, multidimensional scaling, and hierarchical cluster analysis produced a series of interpretable concept maps. Go-zone and pattern match displays were produced to identify points of consensus and discordance between demographic groups.

Results: 27 PA behaviors were identified and conceptualized in a 6-cluster solution. Clusters ranked from highest to lowest frequency were: (1) Household Chores, 3.05; (2) Work-related PA, 2.36; (3) Outdoor PA, 2.15; (4) Family and Friends PA, 1.85; (5) Gym-type Exercises, 1.84; and (6) Structured Sport Activities, 1.49. The most frequently rated PA statements were "yard work" and "cleaning and repairing the house." Men with overweight/obesity showed similar PA behaviors regardless of weight status ($r = 0.94$). Similarly, the PAs of men with $\leq$ high school education were comparable to participants with any college education ($r = 0.99$). Participants ≥ 55 years engaged in PA with family and friends less frequently than those < 55 years ($p < 0.01$).

Conclusion: Men engaged in household chores more frequently than structured sports. Across body weight statuses and education levels, participants engaged in comparable PA behaviors, though men under 55 were more likely to participate in social forms of PA. Health promotion interventions to reduce cancer risk among Central American men with overweight/obesity should address challenges of increasing the frequency of activities they already perform.

I-P-C.08

Body Composition Changes in Patients with Localized Breast Cancer Experiencing Overweight, Obesity, or Recent Weight Gain and Receiving Nutritional Support

M. Langlois¹, M. Mouret Bonzi¹, A. Goerens¹, C. Bourguignon¹, L. Dumont¹, P. Marijnen¹, M. His^{1,2}, O. Péro^{1,2}

¹Centre Léon Bérard, Lyon, France, ²INSERM U 1296, Lyon, France

Purpose: In breast cancer patients, overweight, obesity, and weight gain are linked to poorer treatment tolerance, worse prognosis, and higher recurrence risk. Despite this, many patients are overweight at diagnosis, and over half gain weight during or after treatment. Recent evidence highlights the need to monitor patients during treatments to prevent both weight gain and muscle loss, that should be assessed via body composition analysis.

C. CANCER PREVENTION AND MANAGEMENT

This study aimed to evaluate changes in body composition among patients with localized breast cancer who were overweight, obese, or had recently gained weight, and who received nutritional care, in order to identify patients who benefited most from the intervention.

Methods: This retrospective, single-center observational study included women under 70 with localized breast cancer and either overweight, obesity, or >5% weight gain in the past six months, who were treated at a comprehensive cancer center (Centre Léon Bérard, Lyon, France) between 2019 and 2025, and who received multidisciplinary care including dietary assessment (with bioimpedance analysis), physical fitness evaluation, and medical synthesis. Assessments were conducted twice, six months apart, with optional intermediate follow-up and personalized support (dietary follow-up, nutritionist consultations, therapeutic education workshops, and adapted physical activity programs). Changes in measured body composition, body mass index, and weight between were evaluated using linear mixed effect models.

Results: Among 662 patients (mean age 52), 55% were obese, 37% overweight, and the rest had recent weight gain. At baseline, mean weight was 83.0 kg, with a prior six-month gain of +0.8 kg. Among 261 patients with complete bioimpedance data, BMI ($P=0.001$) and fat mass ($p < 0.001$) significantly decreased, while muscle mass remained stable overall ($p = 0.948$). There was no evidence of heterogeneity by treatment type.

Conclusion: Preliminary results show favorable changes in weight and fat mass, and stable muscle mass, supporting the integration of nutritional care into breast cancer treatment pathways. Body composition assessment and initial weight status should be considered in patient management.

I-P-C.09

Food Insecurity and Sugar-sweetened Beverage Consumption among Cancer Survivors

T. Agurs-Collins¹, A. Acevedo¹, B. Slotman², C. Pichardo³

¹National Cancer Institute, NIH, Division of Cancer Control and Population Sciences, Rockville, MD, United States,

²Westat, Rockville, MD, United States, ³National Institute on Minority Health and Health Disparities, NIH, Bethesda, MD, United States

Purpose: Food insecurity is associated with worse treatment adherence and adverse health outcomes, and low diet quality characterized by low consumption of fruits, vegetables, whole grains, and high consumption of processed foods, high fat, and added sugars among cancer survivors. The current study examined the determinants of food insecurity and associations with diet quality among cancer survivors.

Methods: From December 2021–May 2022, 440 cancer survivors living in the US and UK were surveyed on Prolific. English-speaking individuals reporting a cancer diagnosis were included. Respondents reported sociodemographic, diet-related behaviors (dietary screener questionnaire), and food insecurity- “How often have you been worried about running out of food and not having enough money to buy more?” (not at all vs. some of the time, most of the time, or close to every day). Logistic regression tested sociodemographic characteristics association with food insecurity. Multivariate regressions examine associations between food insecurity and diet quality.

Results: Participants ($M=50.3$ years old; $SD=13.6$) were predominantly white (90.4%), married (77%), female (70%), had overweight or obesity (66%), and employed (60.1%). Additionally, 33% of the households had children under 18. Cancer of the breast ($n = 135$; 31.4%), head/neck ($n = 34$; 8.9%), and cervix ($n = 30$; 8.4%) were most reported. Roughly 27.2% were classified as food insecure. The odds of food insecurity increased among those with a high school degree or less (OR 2.49, CI: 1.37-4.52), some college but not college degree (OR 2.9, CI: 1.75-4.80), unmarried individuals (OR 2.01, CI: 1.17-3.44), and those with children under 18 in the household (OR 1.84, CI: 1.11-3.05). Additionally, food insecurity was associated with increased daily intake of sugar-sweetened beverages ($B = .55$; $p = .0002$).

Conclusion: One in four cancer survivors in this sample were food insecure. Sociodemographic variables were associated with food insecurity, and food insecurity was associated with increased daily intake of sugar-sweetened beverages. These findings can inform behavioral interventions designed to reduce food insecurity, improve diet quality, and reduce adverse health outcomes among cancer survivors throughout treatment and survivorship.

C. CANCER PREVENTION AND MANAGEMENT

I-P-C.10

A Novel Measure of Metabolic Obesity Phenotype and Its Association with Risk of Colorectal Adenoma

L. Li^{1,2}, X. Sun¹, H. Taha¹, S. Venkatesh¹, B. Castrodale¹

¹University of Virginia, Family Medicine, Charlottesville, United States, ²University of Virginia, Comprehensive Cancer Center, Charlottesville, United States

Purpose: Obesity is a probable cause for colorectal cancer (CRC). Commonly used anthropometric measures of obesity, such as BMI, do not completely capture the metabolic dysfunction associated with obesity and risk of CRC. Insulin resistance is a key factor underlying the mechanistic link of obesity to CRC. We here propose a new measure combining waist-to-height ratio (WHtR) and homeostasis model assessment of insulin resistance (HOMA-IR) to define metabolic obesity phenotype and assess its associations with colorectal adenoma, circulating adipokines, and cardiometabolic profile.

Methods: We collected lifestyle risk factors and fasting blood samples from 908 individuals undergoing screening colonoscopy between 2006-2018. Of these, 253 patients had screening detected colorectal adenoma (i.e., cases), and 655 patients were free of any lesions (i.e., controls). HOMA-IR was dichotomized using a clinical cutoff of 2.0. WHtR was dichotomized at the median among controls not using anti-diabetic medication. We defined metabolic obesity phenotype by combining dichotomized HOMA-IR and WHtR, and evaluated its association with risk of colorectal adenoma and circulating biomarkers using multivariable regression models adjusted for potential confounders.

Results: HOMA-IR and WHtR were each independently associated with the risk of colorectal adenoma. The metabolic obesity phenotype HOMA-IR_WHtR showed much stronger risk association (odds ratios [ORs]=1.69–2.56 compared with the low-low reference group, all $P < 0.05$) than either component separately (ORs = 1.68–1.71, $P < 0.05$). HOMA-IR_WHtR was also significantly associated with advanced colorectal adenoma (ORs =2.14–4.17, $P < 0.05$), while for HOMA-IR and WHtR separately, the association was insignificant). In addition, HOMA-IR_WHtR was strongly associated with an adverse cardiometabolic profile, including lower IGFBP1 and adiponectin ($P < 0.01$), higher leptin and leptin-to-adiponectin ratio ($P < 0.01$), elevated triglycerides ($P < 0.01$), reduced HDL cholesterol ($P < 0.01$), and increased systolic blood pressure and hypertension ($P < 0.01$).

Conclusion: These findings suggest that metabolic obesity, defined by the combination of insulin resistance, i.e., HOMA-IR, and central adiposity, i.e., WHtR, captures a broad cardiometabolic profile encompassing both metabolic and vascular risk. This new measure may enhance CRC risk assessment associated with obesity.

I-P-C.11

Psychosocial and Behavioural Predictors of Symptom Burden in Prostate Cancer Survivors: A Latent Profile Analysis

J.K. Zhan¹, H. Xiao¹, T.C. Yip¹, G. Faulkner², C. Sabiston¹, S. Alibhai³, K. Campbell⁴, K. Arbour-Nicitopoulos¹, D. Santa Mina¹, J. Jones⁵, L. Trinh¹

¹University of Toronto, Faculty of Kinesiology and Physical Education, Toronto, Canada, ²University of British Columbia, School of Kinesiology, Vancouver, Canada, ³University of Toronto, Faculty of Medicine, Toronto, Canada, ⁴University of British Columbia, Department of Physical Therapy, Vancouver, Canada, ⁵Princess Margaret Cancer Centre, Department of Supportive Care, Toronto, Canada

Purpose: Prostate cancer survivors (PCS) experience treatment-related side effects (e.g., fatigue). Identifying lifestyle factors contributing to symptom burden can inform tailored supportive care interventions. This study aims to: (a) identify classes of symptom burden in PCS; and (b) examine psychosocial and behavioural factors of classes.

Methods: A cross-sectional analysis of baseline data from a randomized controlled trial among sedentary (>8 h/day) PCS was conducted. A latent profile analysis identified classes of PCS based on anxiety, depression, and fatigue. Logistic regression examined psychosocial (e.g., Multi-Process Action Control Framework), behavioural (e.g., sedentary behaviour [SED]; moderate-to-vigorous intensity physical activity [MVPA]), and demographic/clinical (e.g., treatment type) predictors.

Results: Among PCS ($N=115$; $M_{age}=69.4\pm9.9$ years), the two-class model demonstrated optimal fit (entropy=0.9; smallest class=29.8%). Class 1 “Low Symptom Burden” (70.4%, $N=81$) reported lower fatigue ($M=45.1$, $SE=\pm0.7$), anxiety ($M=2.9\pm0.3$), and depression ($M=2.2\pm0.2$). Class 2 “High Symptom Burden” (29.6%, $N=34$) reported higher fatigue ($M=29.8\pm1.1$), anxiety ($M=7.1\pm0.4$), and depression ($M=6.9\pm0.4$); all $p < .001$. Higher perceived capability for

C. CANCER PREVENTION AND MANAGEMENT

reducing SED (OR=0.57, 95% CI:0.3-0.9, $p=.025$), self-reported MVPA (OR=0.49, CI:0.3-0.8, $p=.009$), and older age (OR=0.44, CI:0.21-0.92, $p=.030$) were associated with lower odds of Class 2. Higher habit formation for reducing SED (OR=0.59, CI:0.3-1.9, $p=.087$) was marginally associated with lower odds of Class 2. University/college education (OR=3.15, CI:1.1-9.5, $p=.041$) was associated with higher odds of Class 2, and higher SED (OR=1.59, CI:0.9-2.7, $p=.081$) was marginally associated with higher odds of Class 2.

Conclusion: Higher MVPA, perceived capability, and habit regarding SED were associated with lower symptom burden, while higher SED was associated with higher burden. Future interventions should enhance self-regulatory skills and habit formation to reduce SED, which may alleviate symptom burden in PCS.

I-P-C.12

Using the TICD Framework and the Behaviour Change Wheel to Understand Implementation of Physical Activity Interventions in the PAC-WOMAN Trial

S. Franco¹, E. V. Carraça¹, I. Nobre², B. Rodrigues¹, C. S. Silva¹, M. N. Silva¹

¹Universidade Lusófona, CIDEFES, Lisboa, Portugal, ²Universidade de Lisboa, Faculdade de Motricidade Humana, Lisboa, Portugal

Purpose: Despite strong evidence supporting physical activity (PA) in cancer care, multiple barriers hinder real-world implementation of recommendations and interventions. A structured approach to process evaluation, guided by implementation science frameworks, can clarify these barriers, but such a process remains underused among cancer survivor trials. This study explored implementation determinants (barriers and facilitators) of two PA interventions for breast cancer survivors in the PAC-WOMAN trial, using the Tailored Implementation for Chronic Diseases (TICD) framework and the Behaviour Change Wheel (BCW).

Methods: This process evaluation was embedded in the PAC-WOMAN trial, which compared brief PA counselling (PAC) with a supervised exercise programme (ExG). Data were collected from twenty-four participants (six focus groups), three implementers (individual semistructured interviews with exercise professionals), and six stakeholders (interviews with oncology doctors and fitness club managers). Content analysis employed an adapted version of the TICD checklist to identify determinants, while the BCW guided the classification of strategies to address these barriers. Implementation monitoring logbooks were analysed for triangulation.

Results: Fifty-one determinants were identified across six TICD domains. Facilitators were mainly individual or interpersonal (e.g., trust, motivation, group dynamics, supportive setting), whereas barriers were mainly structural or systemic (e.g., time constraints, limited financial coverage, lack of policy support). Both interventions demonstrated similar feasibility and attrition rates. BCWinformed strategies to address these barriers encompassed education, training, modelling, enablement, environmental restructuring, and policy actions.

Conclusion: Evidence-based PA interventions require enabling systems for successful implementation. The feasibility of both counselling and supervised exercise programmes was shaped by participants' motivation, implementers' capability, stakeholder engagement, and available resources. To ensure sustainable integration of PA into cancer care, implementation efforts should prioritise policy reform, cross-sector partnerships, professional training, and financial incentives. Using BCW-aligned strategies to strengthen capability, opportunity, and motivation, alongside systemic support, appears to be essential for embedding PA into routine cancer care pathways.

I-P-C.13

Longitudinal Associations of Cardiorespiratory Fitness and Physical Activity with Cognitive Change in Breast Cancer Undergoing Chemotherapy for Breast Cancer: A Prospective Matched-control Study

H. Xiao¹, E. Warner², J. Ryan³, C. Sabiston⁴, G. Ghazinour⁴, S. O'Rourke⁴, L. Trinh⁴

¹University of Toronto, Faculty of Kinesiology and Physical Education, Toronto, Canada, ²Sunnybrook Health Sciences Centre, Toronto, Canada, ³University of Toronto, Departments of Psychology, Toronto, Canada, ⁴University of Toronto, Toronto, Canada

Purpose: Cancer-related cognitive impairment is frequently reported among breast cancer patients receiving chemotherapy. Cardiorespiratory fitness (CRF) and moderate-to-vigorous physical activity (MVPA) are modifiable behavioral factors that may support cognitive health, yet longitudinal evidence during active treatment is limited.

C. CANCER PREVENTION AND MANAGEMENT

This study examined whether baseline CRF and MVPA were associated with changes in objectively assessed cognitive function from pre- to post-chemotherapy in breast cancer (BC) patients compared with age-matched healthy controls.

Methods: This was a prospective study with two time points: baseline (pre-chemotherapy) and approximately five-month follow-up (post-chemotherapy). Participants were stage I–III BC patients undergoing chemotherapy and age-matched healthy controls. Patients were recruited from breast cancer clinics at the Odette Cancer Centre, and controls were recruited from the broader community. Cognitive function was assessed remotely with the NIH Remote Cognition Toolbox Battery (Picture Sequence Memory, List Sorting Working Memory, Oral Reading Recognition, Auditory Verbal Learning). CRF was measured using the remotely delivered 6-minute walk test via Zoom, and MVPA was assessed by accelerometry (i.e., ActiGraph GT3X+). Linear mixed-effects models were adjusted for anxiety and depression.

Results: Participants (N=55; BC N=32; controls N=23) were mostly White (BC 53%, controls 65%), largely married/partnered (BC 69%, controls 74%), and highly educated (>90% post-secondary). Group $\times$ time effects on cognition were not significant across domains in both groups. Higher baseline CRF trended to a positive association with better List Sorting working memory ($\beta=0.02$, 95% CI -0.01 to 0.05 ; $p=0.077$) and Auditory Verbal Learning ($\beta=0.02$, 95% CI -0.01 to 0.03 ; $p=0.077$) but did not predict cognitive changes. In the MVPA models, BC patients had a non-significant lower baseline Auditory Verbal Learning than healthy controls ($\beta=-4.63$, 95% CI -9.84 , 0.57 ; $p=0.081$), time and group $\times$ time terms were likewise non-significant across outcomes.

Conclusion: Higher baseline CRF showed trends toward better cognitive function, but no meaningful changes in cognitive function were observed over the five-month interval. Larger samples with longer, more frequent follow-up are needed to clarify whether CRF or MVPA truly predict domain-specific changes in cognitive function.

I-P-C.14

A Multi-site Mind-body Intervention to Reduce Sitting and Promote Movement in Black Adults

S. Mama¹, M. Buman², L. Cohen³, Y. Li⁴, L. McNeill¹

¹The University of Texas MD Anderson Cancer Center, Department of Health Disparities Research, Houston, United States,

²Arizona State University, Phoenix, United States, ³The University of Texas MD Anderson Cancer Center, Department of Palliative, Rehabilitation and Integrative Medicine, Houston, United States, ⁴The University of Texas MD Anderson Cancer Center, Department of Biostatistics, Houston, United States

Purpose: The purpose of this study was to explore the effects of Harmony & Health (HH), a faith-based mind-body intervention, on device-measured ST and PA among urban and rural Black adults.

Methods: We partnered with churches and community organizations to recruit participants to this multi-site feasibility and acceptability trial. Black adults who were at higher risk of developing cancer (reported not meeting PA recommendations, being sedentary, with overweight/obesity) were randomized to the HH intervention or a health education (HE) attention control group. All sessions were held in-person twice a week for 8 weeks (16 sessions). HH sessions focused on stretching, breathing, and guided relaxation with scripture; HE covered topics related to cancer and chronic disease prevention. Participants completed assessments at weeks 0 and 9 (post-intervention). Thigh-worn accelerometers were used to assess ST, total sedentary time, step count, and PA, and descriptive statistics were used to explore changes in ST and PA from week 0-9 between groups.

Results: 100 Black adults (50 per site) enrolled in the study; 88.0% were retained at week 9. Participants were mostly women (95.0%) in their 50s (M age=54.2 $\pm$ 14.2 years) with obesity (M BMI=35.6 $\pm$ 7.7 kg/m²). HH participants reported positive changes in ST ($\Delta=-18.5$ vs. 4.0 hours/week; $d=0.2$), total sedentary time ($\Delta=-18.4$ vs. 8.5 hours/week; $d=0.3$), and steps ($\Delta=310.5$ vs. -155.7 steps/day; $d=0.4$) compared to HE participants. Participants in HH reported small increases in PA ($\Delta=0.3$ vs. -0.03 MET-hours/week; $d=0.4$) compared to HE participants.

Conclusion: Trends suggest HH led to reductions in ST and slight improvements in PA. HH successfully reached participants and could be an innovative, scalable approach to reduce ST, cancer risk, and premature deaths among Black adults residing in rural and urban communities.

C. CANCER PREVENTION AND MANAGEMENT

II-P-C.01

Physical Activity and Unmet Support Needs of Young Adults Living with and beyond Cancer

J. Denney¹, E. Stamp¹, S. Costa¹, F. Munir¹

¹Loughborough University, School of Sport, Exercise and Health Science, Loughborough, United Kingdom

Purpose: Young adults living with and beyond cancer experience a number of unique challenges to their physical and mental wellbeing in contrast to peers. Facing a cancer diagnosis during early adulthood can often result in an extended period of survivorship laden with a multitude of support needs. Accordingly, understanding the unmet supportive care needs of young adults living with and beyond cancer is crucial to the development of future interventions and the optimisation of overall survivorship care. As such, this study aims to explore the most prevalent unmet needs within this population group

Methods: This cross-sectional, questionnaire-based study explores the unmet support needs of young adults aged 20-39 living with and beyond cancer. Data was collected via self-report questionnaire, including the validated Cancer Survivor Unmet Needs Survey (CaSUN) and quality of life measures (WHO-5). Lifestyle behaviours such as physical activity (GLTEQ) were also explored as a concept in this study, owing to the widely recognised benefits of increased physical activity within this population group

Results: Regression analysis was used to assess the responses given by a group of young adult cancer survivors to the Cancer Survivor Unmet Need Survey. While recruitment is in early stages, preliminary data analysis suggests younger participants experience a high burden of perceived unmet needs, particularly across the quality of life (66%) and information (60%) domains post-diagnosis. Findings to date also highlight a significant reduction in physical activity following a cancer diagnosis, with the majority of participants reportedly not meeting current physical activity recommendations (90%). Further analysis will explore if unmet needs are associated with physical activity levels and quality of life outcomes.

Conclusion: The present study aims to contribute to the literature exploring the unmet supportive care needs of young people diagnosed with cancer, aiding the development and optimisation of cancer support services. Findings thus far suggest there is a need to enhance supportive care services for young adults, with physical activity interventions offering a potential vehicle to support young adults to live well with and beyond cancer.

II-P-C.02

Physical Activity and Quality of Life in Younger Breast Cancer Survivors with Cardiometabolic Comorbidities: Baseline Results from a Dance-exercise Intervention Pilot Study

R. Kehm^{1,2}, D. Bazile¹, M. Eddy³

¹Columbia University, Epidemiology, New York, United States, ²Herbert Irving Comprehensive Cancer Center, New York, United States, ³Moving For Life, New York, United States

Purpose: The growing population of younger breast cancer (BC) survivors faces elevated risks of cardiometabolic comorbidities and reduced health-related quality of life (HRQoL), yet few lifestyle interventions are tailored to their unique needs. To address this gap, we developed an 8-week dance-exercise program for BC survivors under age 50 with cardiometabolic comorbidities, consisting of twice-weekly, one-hour online classes led by fitness instructors trained in cancer survivorship. This analysis evaluated the baseline association between physical activity and HRQoL in this population before the intervention.

Methods: We conducted a single-arm pilot study to evaluate the feasibility, acceptability, and preliminary efficacy of an 8-week dance-exercise intervention for younger BC survivors (n=20). Participants were recruited from a New York City academic cancer center and were eligible if they were under age 50, diagnosed with BC within the past five years, and had at least one cardiometabolic condition (obesity, hypertension, or hypercholesterolemia). At baseline, participants completed questionnaires assessing current physical activity habits and HRQoL using the Functional Assessment of Cancer Therapy–Breast (FACT-B), which includes overall and subscale measures of physical, social/family, emotional, functional, and BC-specific well-being. We used two-sample t-tests to compare HRQoL scores between participants who were regularly active and those who were inactive at baseline.

Results: At baseline, 62% of participants reported not engaging in regular physical activity, although all intended to begin exercising within 30 days. Additionally, 65% reported being somewhat or much less active following their

C. CANCER PREVENTION AND MANAGEMENT

diagnosis. The most cited barriers to exercise during or after cancer treatment were fatigue, depression, and stress/worry. Women who participated in regular physical activity at baseline had significantly higher overall HRQoL scores (105.1 ± 22.1 versus 73.3 ± 19.3 ; $p=0.01$), as well as higher functional (21.8 ± 3.7 versus 14.2 ± 6.2 ; $p=0.01$) and emotional well-being (19.6 ± 5.5 versus 13.8 ± 3.1 ; $p=0.04$) scores compared to inactive women. Although not statistically significant, active women also had higher physical, social/family, and BC-specific well-being scores.

Conclusion: Engaging in regular physical activity is associated with higher HRQoL among younger BC survivors with cardiometabolic comorbidities. Ongoing analyses will evaluate whether participation in the 8-week dance-exercise intervention further improves physical activity levels and HRQoL in this population.

II-P-C.03

Enhancing Intentions for Cancer-preventive Behaviors: Evaluation of Web-based Educational Interventions

F. Herbolzheimer¹, M. Illmann¹, A. Hausmann², K. Steindorf¹

¹German Cancer Research Center, Division of Physical Activity, Cancer Prevention and Survivorship, Heidelberg, Germany,

²University of Freiburg, Medical Center, Freiburg, Germany

Purpose: Modifiable lifestyle risk factors are estimated to account for nearly 40% of all cancer cases. Despite this, awareness of behaviors such as physical inactivity and poor diet as cancer risk factors remains low, highlighting the need for effective health communication strategies. This study aimed to develop and evaluate four educational materials designed to increase cancer literacy and intentions to adopt healthier lifestyles, particularly regarding nutrition and physical activity.

Methods: As part of the CLARO project, a web-based randomized intervention study was conducted. The intervention materials emphasized the modifiability of health behaviors and varied by modality (textual vs. audiovisual) and communication mode (non-narrative vs. narrative). Participants were randomly assigned to one of five groups: non-narrative text, narrative text, non-narrative animation, narrative animation, or control. Health-related behaviors assessed included fruit and vegetable consumption, red and processed meat intake, and physical activity. Participants' intentions to adopt healthier behaviors were measured for each behavior using a single item on a five-point Likert scale.

Results: A total of 1,191 residents of Stuttgart, Germany (53.4% female; $M = 41.0$ years, $SD = 14.4$) participated between January and May 2025. Randomization ensured no significant baseline differences between groups. Post-intervention, all intervention groups reported significantly higher intentions to adopt a healthier diet and increase physical activity compared with the control group (all $p < .01$). For physical activity, the non-narrative animation was associated with the highest intention for being physically active in the future ($\beta = 0.12$, $p = .003$), followed by the non-narrative text and narrative animation. In the narrative animation condition, identification with the characters was positively associated with intentions to pursue a physically active lifestyle, particularly among participants with lower educational attainment ($\beta = 0.30$, $p < .001$).

Conclusion: The CLARO study demonstrates that brief, web-based educational interventions can effectively enhance intentions to adopt healthier lifestyles. Besides text-based approaches, audiovisual materials appear a promising approach for promoting physical activity. Narrative communication elements seem especially effective when integrated into audiovisual formats.

II-P-C.04

Exercise Intensity Responses during Vigorous Intensity Lifestyle Physical Activity (VILPA) in a Sedentary Healthy Population

J. Vilaró¹, M. Daura², L. Ros², A. Quiñónero², G. Fregonezi³, P. Jakszyn⁴

¹Universitat Ramon Llull, Blanquerna Health Sciences Faculty, Global Research on Wellbeing (GRoW), Barcelona, Spain,

²Universitat Ramon Llull, Blanquerna Health Sciences Faculty, Barcelona, Spain, ³Universitat Federal de Rio Grande, Laboratório d'Inovação Tecnológica em Reabilitação, Departamento de Fisioterapia, Natal, Brazil, ⁴Institut Català d'Oncologia, Unitat de Nutrició i Càncer (UNAC), Barcelona, Spain

Purpose: Integrating short bouts of Vigorous Intensity Lifestyle Physical Activity (VILPA)—brief episodes of vigorous effort embedded in daily routines—has emerged as a promising strategy to reduce sedentary behavior, enhance cardiovascular health and reduce cancer risk. Identifying which common activities achieve vigorous intensity levels

C. CANCER PREVENTION AND MANAGEMENT

is essential to guide exercise recommendations for both healthy and chronic disease populations. This pilot study aimed to characterize heart rate (HR) responses during various VILPA activities in sedentary adults and to assess the validity of different wearable HR monitoring devices to be implemented in large-scale interventions.

Methods: Sixteen sedentary healthy adults (44 ± 14 years) performed a standardized laboratory protocol while wearing four HR monitoring devices (Polar H10, Polar Verity Sense, Coros Armband, Coros Pace3, and Apple Watch Series 9). Following an incremental exercise test (IET) to determine maximal heart rate (HRmax), participants completed several 1-minute VILPA tasks with 5-minute seated recovery intervals: sit-to-stand (STS-1min), fast walking (FW), fast walking carrying 5 kg (FW5kg), fast walking on a 14% slope (FW14%), fast walking on a 14% slope carrying 5 kg (FW14%-5kg), stair climbing (SC), descending stairs (DS), and 40-second sprints. Participants also performed free-living VILPA bouts for 3 days while wearing HR monitors.

Results: Mean HRmax during the IET was 177 ± 12 bpm. The peak HR achieved during VILPA activities was: STS-1min 158 ± 11 bpm; FW 156 ± 16 bpm; FW5kg 160 ± 15 bpm; FW14% 155 ± 13 bpm; FW14%-5kg 161 ± 15 bpm; SC 169 ± 15 bpm; DS 150 ± 17 bpm; Sprint 168 ± 22 bpm. All VILPA activities in the lab and during free-living, elicited HRs exceeding 80% of HRmax, indicating vigorous intensity. HR measurements were consistent across devices, except for the Apple Watch, which tended to underestimate intensity.

Conclusion: Common daily-life activities can elicit vigorous intensity when performed with sufficient effort, supporting VILPA as a feasible and time-efficient approach to improve exercise capacity and cardiovascular health. Moreover, affordable HR sensors proved reliable for monitoring VILPA intensity, highlighting their potential use in large-scale interventions and chronic disease populations.

II-P-C.05

Exploring Prostate Cancer Survivors' Views on the Role of a Low-carbohydrate Diet

A. Patel¹, G. Schofield², J. Keogh³

¹South Pacific College of Natural Medicine, Auckland, New Zealand, ²PREKURE, Auckland, New Zealand, ³Bond University, Gold Coast, Australia

Purpose: Based on Epidemiological data, diet could be a risk factor for prostate cancer (PCa) incidence and recurrence. With an increase in PCa survivorship, focus has been placed on the role that modifiable lifestyle factors such as physical activity and diet can have in improving health-related outcomes in PCa survivors. Emerging research indicates that a low-carbohydrate dietary approach could be beneficial for PCa patients and survivors. This study had two main aims: (1) To identify what PCa survivors perceive to be the benefits of a low-carbohydrate dietary approach, and (2) to ascertain if PCa survivors would consider following a low-carbohydrate dietary approach.

Methods: Participants were 16 PCa survivors from Auckland, New Zealand. Participants ranged in age from 57 to 88 years of age. Time since diagnosis ranged from 1 to 17 years (6.5 ± 5.6 years). At recruitment six men were receiving androgen deprivation therapy (ADT) for their PCa. The remaining ten men were in remission and were treatment free. An interview schedule was developed, and participants were individually interviewed. Interview transcripts were analysed using an indicative thematic approach.

Results: A low-carbohydrate dietary approach was perceived to be beneficial for cardiovascular health and weight management. Two participants had adopted this dietary approach because of their PCa diagnosis and to help mitigate treatment-related side effects. In comparison, other participants discussed the need for information regarding how a low-carbohydrate dietary approach could benefit men who were currently receiving treatment for their PCa, as well as for those who were in remission.

Conclusion: A low-carbohydrate dietary approach that focuses on minimising or eliminating simple refined carbohydrates can be beneficial throughout the PCa continuum (from diagnosis and treatment, through to remission and survivorship). This dietary approach can counteract treatment-related side effects associated with androgen deprivation therapy, such as abdominal weight gain, therefore, minimising the associated risk factors for both metabolic syndrome and type 2 diabetes. Men who plan to undertake this dietary approach need to discuss this first with their healthcare practitioner and/or a dietitian to ensure safety in relation to what level and type of carbohydrate intake is appropriate.

C. CANCER PREVENTION AND MANAGEMENT

II-P-C.09

Environmental Exposure in Mining Areas and Lung Cancer Risk: A Retrospective Analysis in Atacama, Chile

H. Martínez-Cortés¹, M. Parra-Saldías¹, J. De Souza-Lima², S. Mahecha-Matsudo³, J. Castro-Piñero⁴

¹Universidad de Atacama, Departamento de Educación Física, Deporte y Recreación, Copiapó, Chile, ²Universidad Andrés Bello, Santiago, Chile, Facultad de Educación y Ciencias Sociales, Instituto del Deporte y Bienestar, Las Condes, Chile, ³Clínica MEDS, Santiago, Chile, Centro de Investigación en Medicina, Deporte, Ejercicio y Salud, Santiago, Chile, ⁴Faculty of Education Sciences, School of Education, University of Cádiz, GALENO Research Group, Department of Physical Education, Cadiz, Spain

Purpose: The Atacama Region presents high levels of environmental exposure due to mining activity, with pollutants such as PM_{2.5} and arsenic associated with lung cancer. This preliminary study evaluates the association between residence in mining municipalities and lung cancer risk, adjusting for demographic and exploratory environmental variables.

Methods: A retrospective analysis was conducted on 121 lung cancer cases (regional databases HRC/HPH, total n = 3,567). Incidence rates were standardized by population (2024 Census, National Institute of Statistics of Chile). Preliminary environmental data included average PM_{2.5} and arsenic levels based on SINCA reports (2020–2023). Statistical analysis was performed using a Cox proportional hazards model (Cox PH) to estimate hazard ratios (HR) for adverse events (death or closed case), adjusted for age, sex, mining municipality, and incidence rate. Pearson correlations were calculated for pollutants. Analyses were performed in Python (statsmodels).

Results: Higher incidence rates were found in mining municipalities (Vallenar: 55.3 per 100,000 inhabitants; Copiapó: 46.2) compared with non-mining ones (e.g., Caldera: 5.3). The Cox model (n = 121, events = 15) showed HR = 3.72 (95% CI: 0.78–17.78, p = 0.1001) for mining municipalities, indicating a non-significant trend toward higher risk. Age (HR = 1.03, p = 0.2937) and sex (HR = 0.96, p = 0.9380) were not significant. Unexpected correlations were observed between pollutants and cancer incidence: r = -0.45 (PM_{2.5}) and r = -0.47 (arsenic), suggesting confounding factors such as migration or limited environmental data.

Conclusion: Preliminary results suggest a trend toward increased lung cancer risk in mining areas, possibly mediated by environmental exposure, although not statistically significant due to limited statistical power (few events). Future studies should integrate verified SINCA data and longitudinal cohorts to enhance the evidence base and support the implementation of air decontamination programs (PDA) in Atacama.

II-P-C.10

Implementation Adaptations and Lessons Learned from a Community-based Exercise Trial for Breast Cancer Survivors: Year 1 of a Hybrid Type I Effectiveness-implementation Study

D. Ehlers¹, M. Cole¹, B. Ernst¹, R. (. Butterfield¹, D. Vega², K. Kunze¹, P. Estabrooks³, J. Austin¹

¹Mayo Clinic, Phoenix, United States, ²Valley of the Sun YMCA, Phoenix, United States, ³University of Utah, Salt Lake City, United States

Purpose: This study describes initial implementation outcomes, adaptations, and lessons in a Hybrid Type I effectiveness-implementation study testing a community-based exercise trial for breast cancer survivors (BCS).

Methods: The trial examines effectiveness of a 6-month aerobic exercise program (AE; n=80), compared to health education (HE; n=80), on neurocognition in 160 BCS. The secondary aim gathers information on implementation success following the RE-AIM framework. BCS are recruited in an urban, academic medical center setting and randomized to AE or HE. AE is led by community fitness center personal trainers (PTs) and follows a titrated schedule of supervision (sessions increasingly unsupervised). HE includes small-group education delivered by hospital-based health educators. This presentation reports preliminary reach and implementation outcomes, adaptations, and lessons from Year 1 of the trial. Reach includes participant yield, rate, and representativeness; implementation includes PT competency/training; fidelity monitoring via direct observation of AE sessions; and AE session completion among BCS.

Results: Of 1,271 BCS contacted, 36 (n=18 AE, n=18 HE) are accrued (2.9% yield). Recruitment began with patient letters and follow-up calls (n=601), yielding 16 accruals at 1.5 per month. Patient portal messages were adopted (n=572), yielding 11 accruals at 2.2 per month and reducing coordinator burden. Despite efforts to engage outside

C. CANCER PREVENTION AND MANAGEMENT

health systems, only three participants were recruited outside the study site. Participants are 64.9±8.7 years-old and 75.0% non-Hispanic White. Among 18 PTs trained (33% experience with cancer populations, competency quiz performance: 70.0±15.7% BCS-specific exercise to 96.7±7.7% adverse events), 9 were maintained based upon engagement and performance. Quarterly learning collaboratives were added to provide updates, augment training, and foster PT peer support. Direct observation is conducted for all first supervised sessions and randomly across remaining supervised sessions. Observations indicate research staff presence at first sessions is essential. AE session completion is 94.1±15.1% and 70.1±53.0% for supervised and unsupervised, respectively.

Conclusion: While the hybrid approach yields rich information on reach and implementation, efforts to prioritize accrual, reduce burden, and overcome recruitment barriers are critical to achieving the primary effectiveness aim. Supervised session completion is high; however, heterogeneity in unsupervised session completion warrants greater monitoring and promotion of unsupervised exercise.

II-P-C.11

A Remotely-delivered Resistance Training Program for Cognitive Function in Prostate Cancer Survivors: A Feasibility Study

S. O'Rourke¹, C. Sabiston¹, L.J. Bernstein^{2,3}, L. Trinh¹

¹University of Toronto, Faculty of Kinesiology and Physical Education, Toronto, Canada, ²University Health Network, Princess Margaret Cancer Centre, Toronto, Canada, ³University of Toronto, Department of Psychiatry, Toronto, Canada

Purpose: Prostate cancer and its treatment are associated with many long-term adverse effects including cancer-related cognitive impairment (CRCI). Remotely-delivered resistance training (RT) offers a promising strategy to address CRCI and support overall physical health and well-being in prostate cancer survivors (PCS) undergoing androgen deprivation therapy (ADT). This study assessed the feasibility of an 8-week, supervised, remotely-delivered RT program. Secondary objectives examined changes in objective and self-reported cognitive function, objective physical function, and self-reported exercise.

Methods: This two-arm, randomized controlled trial (RCT) recruited Stage I-IV PCS through community organizations across Canada between April–September 2025, enrolling participants who were currently or previously on ADT. Participants were randomized to either an 8-week remotely delivered RT program (one live-remote session and one unsupervised session per week) or health education group that received exercise guidelines. Feasibility outcomes included enrolment rate, completion rate, attrition, adherence, adverse events, and participant satisfaction. Secondary outcomes were assessed pre- and post-intervention. Objective cognitive function was measured using the NIH Remote Toolbox Cognition Battery and PsyToolkit, and self-reported cognitive function was evaluated using the Functional Assessment of Cancer Therapy - Cognitive Function (v3). Physical function was measured using the 30s sit-to-stand test (remotely-delivered), and self-reported exercise was measured using the Godin Leisure-Time Exercise Questionnaire. Descriptive analyses were conducted for demographic, clinical, and feasibility outcomes. Secondary outcomes will be analyzed using repeated measures ANOVA.

Results: PCS (N=19; M_{age}=73.1) were randomized to RT (n=9) or usual care (n=10). PCS were White (88.9%) and were ~38.2±48.0 months post-treatment. Enrollment rate was 41.4%, with no attrition. Baseline assessment completion rates were 100% for questionnaires, and cognitive and physical function tests. Post-intervention data collection will be completed in December 2025 and will be presented at the conference. Among the participants who have completed the RT intervention (n=8), adherence to the RT program was high (96% overall), including 98% for live-remote sessions and 94% for unsupervised sessions, with no adverse events. Additionally, participants reported high satisfaction in terms of intervention safety, clarity of exercise instruction, and exercise difficulty.

Conclusion: Preliminary evidence supports the feasibility of an 8-week remotely-delivered RT intervention in PCS, informing the design of future efficacy trials.

II-P-C.12

Does Quality of Life Improve for Adult Cancer Survivors after a 12-Week Structured Exercise Programme? A Secondary Analysis of the Battle Cancer Programme

S. Costa¹, C.-H. Yu¹, A. Gould², C. Robertson², M. Spooner², E. Stamp¹

C. CANCER PREVENTION AND MANAGEMENT

¹Loughborough University, School of Sport, Exercise and Health Sciences, Loughborough University, United Kingdom,

²Battle Cancer Program, Exeter, United Kingdom

Purpose: Cancer survivors experience health challenges that negatively affect their quality of life (QoL). Exercise interventions have been proposed as an effective strategy to counteract this; however, evidence from standardised community-based structured exercise programmes is limited. This study aimed to assess the changes on the QoL of adult cancer survivors following the Battle Cancer Programme, and check whether change is predicted by age, sex or cancer type.

Methods: A secondary data analysis was conducted with 29 cancer survivors (79% women; mean age 50 years (24-69 years); 62% breast cancer) who had complete QoL data pre- and post-exercise programme. The Battle Cancer Programme (<https://www.battlecancer.com/>) consists of two 1-hour sessions/week of resistance, aerobic, and conditioning exercises. Participants reported age, sex and cancer type via a survey; cancer type was classified as breast or other cancers. QoL was assessed pre- and post-programme completion, using the World Health Organization's WHOQOL-BREF assessment, which assesses QoL in 4 domains: Physical Health, Psychological Health, Social Relationships, and Environment. Participants score items on a 5-point Likert scale, and these are converted to a standardised 0-100 points scale (higher scores represent higher QoL). We calculated the difference between post- and pre-programme scores and used paired- t-tests to assess if there were significant changes in each of the WHOQOL-BREF domains. Multiple linear regressions were used to assess whether age, sex or cancer type predicted change in each of the WHOQOL-BREF domains.

Results: Significant improvements were observed in the Physical Health (mean change: +12.44; $p=0.002$), Psychological Health (+16.38; $p=0.002$), and Environment (+7.97; $p=0.010$) domains, with medium effect sizes (Cohen's $d=0.51-0.65$). The Social Relationships domain showed a small but not significant improvement (+8.91; $p=0.149$). Age, sex and cancer type did not significantly predict change in any of the 4 QoL domains.

Conclusion: The Battle Cancer Programme shows potential to enhance QoL in cancer survivors, independent of age, sex and cancer type. Future research using a randomised-control trial and cancer-specific outcomes (e.g., cancer-related fatigue) are needed to confirm these findings and provide evidence for causal inference.

II-P-C.13

A Habit-based, Randomized Controlled Trial for Reducing Sedentary Behaviour in People Living with and beyond Cancer: A Feasibility Study Protocol

D. Khalaf¹, K. Arbour-Nicitopoulos¹, J. Gillen¹, H. Xiao¹, L. Trinh¹

¹University of Toronto, Faculty of Kinesiology and Physical Education, Toronto, Canada

Purpose: People living with and beyond cancer (LWBC) experience long-term treatment-related side effects such as reduced quality of life (QoL). Although reducing sedentary behaviour (SED) improves health outcomes, there are few sedentary behaviour interventions conducted in individuals LWBC and none explicitly grounded in habit theory, which targets automatic behavioural processes. Therefore, the primary objective of this study is to examine the feasibility of an 8-week habit-based intervention to reduce SED in individuals LWBC. Secondary objectives include examining changes in physical function, QoL, habit, and SED.

Methods: Individuals LWBC (N=30) will be recruited through cancer care organizations, cancer support groups, and posting recruitment posters on community boards and social media. Eligibility criteria include: (1) ≥ 18 years old; (2) localized or asymptomatic metastatic cancer diagnosis; (3) primary cancer treatment completion; and (4) sedentary (self-report >8 hours per day). Participants will be randomized into an intervention group (weekly habit-based tick-sheets consisting of tips to reduce SED) or active control group (movement guidelines and handout about SED). An example of a tip is "during ad breaks, climb up and down your staircase to reduce cancer-related fatigue associated with prolonged sitting." The intervention group will receive check-in sessions for further tailoring of tips. Outcomes will be measured pre- and post-intervention. SED will be measured using inclinometers and the AusDiab3 Sedentary Behaviour Questionnaire. Physical function will be measured remotely using the 30s sit-to-stand test and the 6-minute walk test. Habit will be measured using the Self-Report Behavioural Automaticity Index. QoL will be measured using the Functional Assessment of Cancer Therapy- General and Short Form-12 questionnaires.

Results: A priori feasibility indicators of success are $\geq 70\%$ check-in session adherence, $\geq 70\%$ tip adherence, $<30\%$ attrition, and no adverse events. Descriptive statistics will be used to characterize the sample's demographic, clinical, and feasibility outcomes. Preliminary intervention effects on secondary outcomes will be explored using intention-to-treat analyses and analysis of covariance models while controlling for the baseline value of the outcome.

C. CANCER PREVENTION AND MANAGEMENT

Conclusion: Study findings will inform larger randomized controlled trials to reduce SED in people LWBC. This intervention may be a cost-effective and accessible option for individuals LWBC to optimize their health.

II-P-C.14

Feasibility of Implementing a Tailored Rehabilitation Programme as Standard Care among People diagnosed with Lung Cancer: CanBenefit 3 Protocol

B. Williams¹, A. Bullock², H. Gordon³, J. Curry⁴, J. Cohen¹, M. Pearson³, M. Twiddy³, C. Huang¹, C. Pompili³, A. Salawu⁵, C. Forbes³

¹University of Hull, Hull Health Trials Unit, Hull, United Kingdom, ²University of Hull, Sport, Exercise, and Rehabilitation Sciences, Hull, United Kingdom, ³University of Hull, Hull York Medical School, Hull, United Kingdom, ⁴Colorado State University, Health and Exercise Science, Fort Collins, United States, ⁵Hull University Teaching Hospital NHS Trust, Rehabilitation Medicine, Hull, United Kingdom

Purpose: Lung cancer is third most common cancer in United Kingdom and most common cause of cancer death. Lifestyle interventions show improvement in quality of life (QoL), physical function, cancer treatment completion, recovery, and survival rates among breast, bowel, and prostate cancer, with promising evidence for lung cancer. Previously, we examined feasibility and acceptability of wellbeing counselling to people with lung cancer during treatment. We found benefits for overall wellbeing, but significant trial recruitment issues lead to small and unrepresentative samples. If standard care, all eligible patients could be referred and potentially benefit. This study aims to understand how best to embed a service (exercise physiologist (EP)) referral, routine measures collection, and tailored rehabilitation programme) into lung cancer care pathways.

Methods: In this multisite, feasibility, implementation study, clinicians will identify eligible patients in clinics and refer them to the EP. All patients attending the referral appointment receive the initial assessment and a personalised wellbeing programme with tailored information, with pre-defined criteria for more support based on need. Programmes are delivered “digital first” with paper-based options. All outcome measures are collected as part of standard care and recorded in electronic health records. A 12-month referral period aims to engage at least 300 people in the service. Follow-up assessments are completed at 3, 6, and 12 months.

Results: Primary feasibility aims are assessed by clinician referral rates, referral uptake rates, programme acceptability and engagement, ease of routine measures collection, and programme-related injuries. Secondary objectives will determine potential impact of the programme on changes in clinical outcomes (treatment completion rates, 1-year survival), physical function (cardiovascular endurance, muscular strength and endurance), patient-reported outcomes (cancer-specific QoL, breathlessness) and lifestyle behaviours (activity, nutrition, and sleep).

Conclusion: 25% of lung cancer diagnoses in England among those least deprived survive five years or more, compared to 18% of those most deprived. As standard care, referring all eligible patients reaches outside the usual wealthier, more educated, motivated, white women. Beyond survival gains, the intervention’s patient-centred approach affirms the worthiness of supportive care for underserved groups, often denied access, paving the way for broad culture change around lung cancer outcomes among disadvantaged populations.

II-P-C.15

Reclaiming Identity Through Exercise: Insights from the Battle Cancer Program

L. Jones¹, C. Stevinson¹, S. Costa¹, M. Morris¹, C. Robertson², M. Spooner², A. Gould², E. Stamp¹

¹Loughborough University, School of Sport, Exercise and Health Sciences, Loughborough, United Kingdom, ²Battle Cancer, London, United Kingdom

Purpose: Cancer survivorship often disrupts individuals’ sense of identity, with changes to physical capacity, appearance and social roles contributing to psychological distress and diminished self-concept. Although exercise is increasingly recognised as a tool to support physical and emotional recovery, limited research has explored how structured, communitybased exercise programs support identity reconstruction after cancer. This study aimed to explore how participation in the 12-week Battle Cancer Program, a functional fitness intervention integrating physical, psychological and social support, influences identity reconstruction and psychosocial recovery among cancer survivors.

C. CANCER PREVENTION AND MANAGEMENT

Methods: Semi-structured interviews were conducted with 8 participants who have completed cancer treatment, aged over 18 years, and attended the Battle Cancer Program (<https://www.battlecancer.com/>). Interviews included open ended questions designed to encourage participants to reflect on their experiences of identity, recovery and the role of exercise following the completion of cancer treatment. All interviews were audio recorded, transcribed verbatim and analysed using Braun and Clarke's reflexive thematic analysis.

Results: Three interconnected themes were generated: (1) Reclaiming Identity Through Physical Empowerment, (2) Community as a Catalyst for Recovery (3) Exercise Continuity and Future Self. Together these themes demonstrated how the Battle Cancer Program supported cancer survivors in rebuilding identity through the combined effects of physical gains, social connection and sustained engagement with exercise, enabling participants to move beyond illness-defined identities. Collectively, they highlight the programs role in fostering confidence, autonomy and a renewed sense of capability as individuals navigated life after cancer.

Conclusion: Findings demonstrated that exercise enabled participants to regain strength, rebuild self-concept, resist illness defined identities and encouraged the development of pride and autonomy. Participation in a supportive group environment reinforced social connection, motivation and a sense of belonging, while lifestyle integration of exercise promoted sustained engagement and future oriented goal setting. The Battle Cancer Program therefore functioned as both a rehabilitative tool and a catalyst for psychosocial adaptation, illustrating how structured, community-based exercise supports identity reconstruction among cancer survivors. Implications include the value of designing exercise programs for cancer survivors that extend beyond physical rehabilitation, by embedding social, psychological and personalised elements into survivorship support.

II-P-C.16

Walking in Nature (WIN) for Rural Cancer Survivors: Feasibility and Preliminary Outcomes of a Pilot Nature-based Physical Activity Intervention

G. Besenyi¹, C. Reavey¹, S. Nyp¹, A. Mattox¹, A. Ross¹, A. Field¹, E. Mailey¹

¹Kansas State University, School of Health Sciences, Manhattan, United States

Purpose: Advances in cancer treatment have led to a growing population of survivors who experience long-term physical and mental health challenges, including fatigue, reduced physical function, anxiety, and depression. Physical activity (PA) can help mitigate these effects, but rural cancer survivors often face barriers to participation, including limited access to programs. Nature-based PA interventions represent a promising yet understudied approach for survivorship in rural contexts. This pilot study evaluated the feasibility, acceptability, and preliminary effectiveness of Walking in Nature (WIN), a nature-based PA intervention for rural cancer survivors.

Methods: WIN used a mixed-methods, single-group pre/post pilot design. Data were collected in Summer/Fall 2025. Participants attended twice-weekly, 60-minute outdoor PA sessions for 12 weeks led by an ACSM-certified Cancer Exercise Specialist. Sessions included walking, light resistance training, mindfulness activities, and behavioral support. Feasibility and acceptability were assessed through attendance, session enjoyment, and post-program interviews. Preliminary effectiveness outcomes included changes in fitness (6-Minute Walk Test), fatigue, pain, anxiety, depression, and quality of life (QOL). Paired t-tests examined quantitative outcomes. Qualitative data were analyzed thematically.

Results: Participants (n=13) were primarily White (100%), female (84.6%), and older adults ($M=65.7, SD=10.0$), representing multiple cancer types. Attendance benchmarks were met (72.5%), and acceptability was high (mean enjoyment=4.5/5). Fitness significantly improved from pre6MWT ($M=1296.44, SD=187.28$) to post6MWT ($M=1455.91, SD=184.92$), $t(9)=5.43, p<.001$. Most participants (7/9) reported improved social support from friends, though not significant. Self-efficacy for exercise and spending time in nature decreased slightly ($t(9)=-2.35, p=.043$; $t(9)=-2.84, p=.19$). Qualitative findings highlighted the social, restorative, and motivational aspects of nature-based PA. One participant noted, "This [program] has changed my life. I now enjoy walking. I do it on purpose now."

Conclusion: Findings support the feasibility and acceptability of a nature-based PA intervention for rural cancer survivors. Preliminary improvements in fitness and positive participant experiences suggest promise for this approach and warrant a larger randomized controlled trial. Nature-based PA may represent a scalable strategy to enhance survivorship care in rural communities.

I-P-D.01

Analytical Validation of Wrist- and Hip-step Count Algorithms: The Importance of Physical Function

S. Strath¹, R. Marcotte², K. Lyden², A. Swartz¹

¹University of Wisconsin-Milwaukee, Kinesiology, Milwaukee, United States, ²Vivosense, Inc., Newport Coast, United States

Purpose: Accurate step counting is vital for population surveillance and physical activity interventions, yet device placement and user mobility may influence measurement accuracy. This study compared the accuracy of open-source accelerometer step counting algorithms from wrist- and hip-worn devices across different levels of physical function (PF).

Methods: For this cross-sectional observational validation study conducted under free-living conditions, 148 adults (mean age = 61.7 ± 20.3 y) completed the Short Physical Performance Battery (SPPB) and participated in three free-living 2-hour observation periods (FL-2hr) while wearing accelerometers on the left wrist and hip (ActiGraph; AG) and thigh (activPAL; AP). Participants then wore all devices for seven consecutive days (FL-Week). ActiGraph wrist (AG-Wrist) and hip (AG-Hip) step estimates were extracted and the open-source Ducharme step algorithm estimates were derived using raw wrist data (D-Wrist). Criterion step counts were obtained from the thigh-worn AP. Linear mixed-effects models with random intercepts for participants estimated group-level bias (percent error; PE) and individual-level precision (absolute percent error; APE). Nested mixed-effects models with and without SPPB were compared using likelihood ratio tests, adjusting for age and total AP steps ($\alpha = 0.05$).

Results: Steps were underestimated using AG-Hip (-18.0% [-21.1%, -15.0%]) and overestimated using AG-Wrist (60.2% [51.0%, 69.4%]) and D-Wrist (61.4% [51.1%, 71.8%]). Performance of wrist-based step algorithms differed by visit type ($p < 0.05$), whereas AG-Hip performance was comparable between FL-2hr and FL-Week ($p > 0.05$). For AG-Hip, inclusion of SPPB improved model fit for both PE ($\chi^2(1) = 7.87$, $p = 0.005$) and APE ($\chi^2(1) = 15.01$, $p < 0.001$), and remained after adjusting for total AP steps (PE: $\chi^2(1) = 24.27$, $p < 0.001$; APE: $\chi^2(1) = 31.59$, $p < 0.001$). In contrast, SPPB did not improve model fit for either wrist-based algorithm—AG-Wrist (all $p \geq 0.89$) or D-Wrist (all $p \geq 0.18$)—indicating wrist step counting accuracy was not influenced by PF.

Conclusion: Physical function influenced the accuracy of the hip-worn but not wrist-worn step counting algorithms. Hip placement may better capture function-related differences in mobility, whereas wrist-based estimates may lack precision and reliability to attribute measurement error to PF status. Wear location and mobility should be considered when interpreting device-based step counts in public health and behavioral research.

I-P-D.02

Effectiveness of Dynamically Tailored Mhealth Interventions for the Promotion of Healthy Diet-related Behaviours among Adolescents: A Systematic Review

A. Ramuscak¹, N. Braganza¹, D. Mager², J. Haines¹, K. Walton¹

¹University of Guelph, Guelph, Canada, ²University of Alberta, Edmonton, Canada

Purpose: Globally, adolescents fail to meet dietary guidelines and engage in unhealthy eating behaviours. Dynamically tailored mobile health (mHealth) interventions offer a promising platform for improving adolescent diet, as smartphone ownership among youth has surpassed 90% in most middle to high income countries. These interventions can deliver timely, personalized information to enhance access, relevance, and behavioural impact. This systematic review explored dynamically tailored mHealth interventions aimed at improving diet-related behaviours among adolescents, examining key components, theoretical underpinnings, feasibility, acceptability, and sustained behaviour changes.

Methods: Seven electronic databases were searched using keywords related to adolescents, mHealth interventions, and diet-related behaviours. Study quality was assessed using mHealth Evidence reporting and assessment checklist (mERA) and Cochrane's risk of bias tool for randomized trials (ROB-2), as applicable. Findings were narratively synthesized to summarize intervention characteristics, quality, and effectiveness.

Results: Nine studies involving 2,613 adolescents (mean age 12.7-18.3 years) with average sample sizes of 20-1,198 participants. Interventions targeted various diet-related behaviours, including general healthy eating habits (e.g., fruit and vegetable consumption), sugar consumption, iron intake, eating rate and disordered eating. Three of nine

D. E- & mHEALTH

studies were informed by a behaviour change theory. Common app components included feedback mechanisms (automated messages, human-delivered feedback, or gamification; $n=8$), self-monitoring ($n=6$), social supports ($n=4$), and cognitive tools ($n=2$). Several studies reported improvement in at least one dietary, psychosocial, or anthropometric outcome, however effects were often modest or not sustained. Feasibility and acceptability of the mHealth interventions ($n=3$) were mixed. Attrition was a common limitation, with 8 studies reporting rates $>55\%$. While most studies ($n=5$) detailed intervention delivery and content, few reported on the feasibility or acceptability of the intervention ($n=3$) or details of app cost, adaptability, or regulatory compliance ($n=8$). Two out of three studies assessed for risk of bias using the RoB-2 were considered to have a risk of bias.

Conclusion: Dynamically tailored mHealth interventions show emerging potential to support diet-related behaviours among adolescents. Although several studies demonstrated positive outcomes, effectiveness remain limited by high attrition rates and lack of sustained impact. Addressing these gaps may enhance effectiveness and sustainability of adolescent nutrition interventions.

I-P-D.03

Using Artificial Intelligence (AI) to Assist Students' Behavior Management for Obesity Prevention in Middle Schools: A Feasibility Study

Q. Tan¹, Y. Nie¹, P. Son¹, Y. Qian¹, P. Yang¹, A. E. Staiano², F. Wang³, R. R. Rosenkranz⁴, S. Chen¹

¹Louisiana State University, School of Kinesiology, Baton Rouge, United States, ²Pennington Biomedical Research Center, Baton Rouge, United States, ³Louisiana State University, Department of Geography & Anthropology, Baton Rouge, United States, ⁴University of Nevada, Department of Kinesiology & Nutrition Sciences, Las Vegas, United States

Purpose: Adolescent obesity remains a pressing public health challenge, particularly among socioeconomically disadvantaged populations. This study evaluated the feasibility and preliminary behavioral impact of *ProudMe Tech*, an AI-assisted web application designed to help middle school students self-manage obesity-related behaviors: physical activity, screen time, diet, and sleep, within naturalistic school settings.

Methods: As part of a larger multi-component obesity prevention intervention, this study focused on evaluating *ProudMe Tech* used by students at five public middle schools in Louisiana, USA. Of the 487 students who created an account, 172 submitted parent consent and assent. The participants ($N=172$) used *ProudMe Tech* to set SMART (specific, measurable, attainable, realistic, and timely) goals, record behaviors, write reflections, and receive AI-generated feedback. Engagement data (journal entries, reflections, AI feedback) were recorded and processed for analysis. Natural language processing examined sentiment of the user reflections and AI feedback. Paired t-tests were conducted to compare the four health behaviors at two points (first week vs. last week) to gauge behavioral impact.

Results: Participants logged 6,164 goals over eight weeks, 63.8% of which were self-reported as achieved. Participants entered 8.9(95% CI[7.8, 10.0]) behaviors, wrote 30(95% CI[25.8, 34.3]) reflections, and received 33.5(95% CI[29.1, 38.0]) AI feedback messages. Sentiment analysis indicated predominantly neutral-to-positive tones in both user reflections and AI feedback messages. Feedback patterns were dominated by positive reinforcement (60%) and educational prompts (28%), followed by constructive suggestions (12%). Significant pre-to-post reductions were observed for screen time (4.3(95% CI[3.9, 4.7]) to 3.4(95% CI[3.0, 3.7]) h/day; $\Delta M = -0.93$ h/day; $p < 0.001$) and slight reduction in fruits/vegetable intake 5.7(95% CI[5.1, 6.3]) to 5.2(95% CI[4.7, 5.7]) servings/day; $\Delta M = -0.50$; $p = 0.024$). Physical activity and sleep did not show significant changes.

Conclusion: The findings demonstrate the feasibility of *ProudMe Tech* as an AI-assisted behavior management tool in school settings. The AI feedback patterns, predominantly positive reinforcement, reflected supportive behavioral strategies consistent with promoting user engagement. While these patterns supported engagement and behavioral impact (notably in screen time), future iterations should explore diversifying feedback strategies, such as increasing constructive suggestions and integrating parental engagement, to sustain broader health behavior changes.

I-P-D.04

Snacktivity™ to Promote Physical Activity during Pregnancy: Feasibility Randomised Controlled Trial and Nested Qualitative Study

K. Sharp¹, A. Daley¹, L. Sherar¹, J. Sanders¹

¹Loughborough University, SSEHS, Loughborough, United Kingdom

D. E- & mHEALTH

Purpose: Pregnant women are advised to complete ≥ 150 minutes of moderate-intensity physical activity per/week for optimal health, yet many fall short. Updated guidelines for pregnant women now support any duration of activity, removing the stipulation that activity should be performed in ≥ 10 -minute bouts. Consequently, a short bout Snacktivity™ intervention was adapted for pregnant women and a feasibility randomised controlled trial with nested qualitative study was conducted.

Methods: Pregnant women between 10⁺ and 16⁺ weeks gestation were recruited at their antenatal dating scan appointments, or via social media. Participants were enrolled from (~18-weeks gestation) until 36-weeks gestation (~18 weeks total duration), and individually randomised (2:1 ratio) to a Snacktivity™ physical activity intervention plus standard antenatal care, or to standard antenatal care (comparator). The Snacktivity™ intervention focused on promoting participation in 2-5 mins activity snacks throughout the day to achieve ≥ 150 minutes of moderate intensity activity per/week. The intervention involved a mobile health app, tailored to pregnant women, which was linked to Fitbit smartwatch to support participation in Snacktivity™ and physical activity during pregnancy. The primary outcome was the feasibility and acceptability (recruitment rate, adherence Snacktivity™ and attrition) of the trial and Snacktivity™ intervention according to traffic light stop-go criteria (red/amber/green). Accelerometer-measured physical activity, gestational weight gain and psychological health outcomes were assessed via exploratory analyses at baseline and 36 weeks follow-up. At the end of trial, 15 participants in the Snacktivity™ intervention group completed an interview about their experiences.

Results: Ninety-six participants were recruited in six months (against target of 90) and 14/96 (14.6%) participants did not provide follow-up data (green for both criteria). Snacktivity™ adherence met the red criteria as 13/54 (24.1%) participants completed on average ≥ 4 activity snacks per/day across the whole intervention. Adjusted mean differences in total minutes of physical activity, gestational weight gain, and depression scores favoured the Snacktivity™ intervention group at follow-up. Qualitative insights found that intervention participants viewed the Snacktivity™ intervention positively, and new physical activity habits were developed.

Conclusion: With modifications to increase adherence, the Snacktivity™ intervention has potential to be a feasible and acceptable approach to promoting physical activity during pregnancy.

I-P-D.05

Do AI-driven Physical Activity and Sedentary Behaviour Interventions Impact Glycemic Outcomes in Adults Living with Type 2 Diabetes? A Rapid Review

Y. Genaidy¹, M. Mitchell¹

¹Western University, Kinesiology, London, Canada

Purpose: This review aimed to evaluate the effects of artificial intelligence (AI)-driven physical activity (PA) and sedentary behavior (SB) interventions on glycemic outcomes in adults with type 2 diabetes (T2DM). By synthesizing recent evidence (post-2020), this study addressed whether AI-integrated tools improve HbA1c, insulin sensitivity, or glucose variability. This research provides an innovative focus that bridges AI technology, T2DM self-management, and PA/SB research.

Methods: Following Cochrane Rapid Review Guidelines, Embase, CENTRAL and PubMed were searched for peer-reviewed studies published since March 2020. Eligible studies included quantitative research evaluating AI-driven interventions targeting PA or SB in adults living with T2DM. Studies reporting the following glycemic outcomes were included: glycated hemoglobin (HbA1c), insulin sensitivity (e.g., Homeostasis Model Assessment of Insulin Resistance [HOMA-IR]), and glucose variability e.g., (Time in Range [TIR]).

Results: Three studies were included (two pre-post single cohort studies, one randomized controlled trial; n=277; mean age 54.52 years, 40.07% female). All three examined the impact of AI-integrated mobile health applications (mHealth apps) for PA on HbA1c. None examined impact on SB. Two studies reported clinically significant HbA1c reductions (0.40% and 0.49%, respectively), with one revealing significant reductions in sub-group analyses only (0.80% among those with baseline blood glucose >180 mg/dL). One study found a modest overall increase of 1.1% in TIR, which was more pronounced in subgroups with elevated baseline glucose (15%, equivalent to 3.5 hours per day). Insulin sensitivity and glucose variability were not reported in any study.

Conclusion: Overall, the limited evidence suggests AI-driven PA interventions improve glycemic outcomes in adults with T2DM, with HbA1c reductions comparable to those achieved in broader digital self-management interventions. However, evidence quality was limited by the short intervention durations (12-16 weeks), heterogeneity in study design, and potential conflicts of interest. Importantly, no study assessed AI tools for SB reduction, a missed opportunity given its independent role in glycemic health. More, higher-quality studies (e.g., RCTs) examining whether AI-driven tools can support PA and/or SB in T2DM self-management are needed.

Validation of the SENS Monitor for Physical Activity Assessment in Free-living Adolescents Using Video and Ecological Momentary Assessment: A Study Protocol

H. Coughlin^{1,2}, J. Ma³, B. Herman Hansen³, A.E. Donnelly^{1,2}, INDEEP MSCA Doctoral Network

¹University of Limerick, Physical Education and Sport Science, Limerick, Ireland, ²University of Limerick, Health Research Institute, Limerick, Ireland, ³University of Agder, Sport Science and Physical Education, Kristiansand, Norway

Purpose: Development of accurate Physical Activity (PA) measurement devices is critical as self-reported data is subject to biases, and many objective tools fail to capture the sporadic nature of PA in adolescents. The SENS motion® activity monitor (SENS motion, Copenhagen, Denmark) is a novel, lightweight, thigh-worn device. SENS outputs have not previously been assessed compared to indirect calorimetry in adolescents, nor is behavioural identification available for adolescents using SENS. This study aims to (1) validate the SENS monitor for PA intensity classification and behaviour recognition in adolescents aged 12–14 years, and (2) employ machine-learning methods to develop and evaluate algorithms to identify movement behaviours using ground truth data from both worn video cameras and from smartphone-based responses to ecological momentary assessment (EMA) questions during free living. This study is funded by the European Union under Agreement #101120480.

Methods: Following ethics committee approval, a total of 100 healthy adolescents aged 12–14 years old will be recruited in Limerick, Ireland and Kristiansand, Norway. Participants will complete a lab-based session fitted with portable metabolic analyzers and SENS monitors. The lab session includes a structured protocol of an hour of 16 activities of varying intensities and an hour of semi-structured activities simulating free-living. Participants then complete a 3-day free-living protocol, wearing the SENS monitor, during which they will receive daily EMA prompts on their phones to report PA behaviours. For the first 10 hours free-living, a downward-facing video camera will capture contextual information about their activities. Video annotations and EMA responses will be employed to label accelerometer data, and this will be used to train machine-learning algorithms for the SENS device.

Results: Data collection is planned for March–May 2026. The video and EMA labelled accelerometer data will be used to develop machine-learning models to predict PA energy expenditure and PA behaviour. These methods will later be employed in the INDEEP project's main data collection across Europe.

Conclusion: This study will provide the first free-living validation of the SENS accelerometer in adolescents. Findings will advance PA measurement accuracy, support improved PA behaviour assessment methods, and add to the literature exploring the potential of EMA for PA behaviour measurement.

I-P-D.07

Interactional Preferences during Supervised Live-remote Exercise Programs: An International Concept Mapping Study with Individuals Living beyond Cancer

E. de Jongh¹, A. Hiensch², L. Buffart³, D. Binyam², A. Kias⁴, K. Steindorf⁴, N. Gunasekara⁵, D. Clauss⁶, Y. Wengström⁷, P. Anandavadivelan⁷, E. Zopf⁸, M. Trevasakis⁸, J. Belloso⁹, I. Perez-Ruiz⁹, C. Rezola-Pardo⁹, A. Alves¹⁰, P. Antunes¹⁰, C. Garcia¹⁰, N. Aaronson¹, A. May², M. Stuiver¹

¹Netherlands Cancer Institute, Psychosocial Research and Epidemiology, Amsterdam, Netherlands, ²University Medical Center Utrecht, Utrecht, Netherlands, ³Radboud University, Nijmegen, Netherlands, ⁴German Cancer Research Center, Heidelberg, Germany, ⁵German Sport University Cologne, Cologne, Germany, ⁶National Center for Tumor Diseases, Heidelberg, Germany, ⁷Karolinska Institute, Stockholm, Sweden, ⁸Cabrini Health, Malvern, Australia, ⁹Biogipuzkoa Health Research Institute, San Sebastian, Spain, ¹⁰Associação de Investigação de Cuidados de Suporte em Oncologia, Lisbon, Portugal

Purpose: The recent surge in live-remote exercise programs may facilitate greater patient access to rehabilitation and support restorative habits, but concerns have been raised about altered or weakened interpersonal dynamics between participants and trainers. As part of the EU-funded PREFERABLE II LION-RCT, investigating the effectiveness of a live-remote exercise program for people living beyond cancer who still experience side-effects, we conducted a concept mapping study assessing participants' preferences regarding social dynamics. In doing so, we identify aspects of social interaction considered to be essential within these programs. This study contributes to the growing body of literature aiming to promote positive affect towards live-remote exercise initiatives and improve their design for this population.

D. E- & mHEALTH

Methods: Individuals living beyond cancer from six countries (Australia, the Netherlands, Germany, Sweden, Spain, and Portugal) were included in this mixed methods concept mapping study after completion of a 12-week live-remote exercise program targeting the negative side effects of their treatment. Participants completed (1) a brainstorm phase (generating statements in response to two focus prompts; one related to peer-interaction and one to interaction with the trainer); and/or (2) a sorting and rating phase. In the latter phase, patients sorted statements into groups of related concepts and rated them according to perceived importance. Trainers or involved researchers simultaneously rated whether these preferences can be realistically implemented in practice. The survey was completed using an online concept mapping platform (GroupWisdom) and participant data were pseudonymised.

Results: (Results Pending) Participants generated 101 unique statements reflecting their preferences for interacting with their peers and the trainers. Data collection and analysis will be completed by April 2026. The sorted statements will be aggregated using cluster analysis. The “Go-Zone map” will combine ratings of importance and feasibility, informing which interactional features should be prioritized in online exercise interventions.

Conclusion: We expect this study will provide actionable insights on preferences of people living beyond cancer for optimizing interpersonal dynamics with their peers and trainers during live-remote exercise. The identified set of preferences – according to importance and feasibility – will contribute to guidelines for designing live-remote exercise initiatives.

I-P-D.08

AI-driven Personalised Recommendations and Real-time Monitoring for the Prevention and Management of Obesity: Design and Pilot Evaluation of the Multicentre BETTER4All Personalised Intervention

Purpose: This abstract presents the design and implementation framework of the BETTER4All trial, a multicentre randomised controlled trial (RCT) within the EU-funded BETTER4U project. The trial aims to evaluate an artificial intelligence (AI)-driven, biologically and behaviourally personalised lifestyle intervention for the prevention and management of obesity. The project seeks to move beyond the traditional “one-size-fits-all” approach by integrating genetic, metabolic, behavioural, and environmental data into adaptive, individualised care strategies.

Methods: The BETTER4All trial will be conducted across seven European countries (Greece, Cyprus, Portugal, Spain, France, Poland and Sweden), including 1,022 adults with overweight and obesity (BMI ≥ 25 kg/m²). Participants will be randomised to an intervention group receiving AI and polygenic risk score (PRS)-based lifestyle recommendations via a smartphone application, wearable device, and structured counselling, or to a control group receiving standard care and a light version of the app for self-monitoring. The primary outcome is change in BMI at six months. Secondary outcomes include weight-loss maintenance at one year, metabolomic and gut microbiota biomarkers, lifestyle behaviours, and psychosocial parameters. A mixed-methods process evaluation will assess fidelity, acceptability, feasibility, and appropriateness, alongside adherence metrics from the digital tools through continuous behavioural and contextual monitoring.

Results: The pre-trial pilot study, conducted across all seven sites and concluding in December 2025, aims to test the

D. E- & mHEALTH

feasibility, usability, and acceptability of the digital tools and intervention procedures. Results from the pilot's process evaluation—focusing on participant engagement, healthcare provider experience, and implementation fidelity—will be presented. These findings will inform the optimisation of the full-scale RCT, which is scheduled to commence in February 2026.

Conclusion: The BETTER4All trial will provide evidence on the effectiveness and scalability of AI-driven, biologically informed personalisation in obesity care, offering a methodological framework for integrating multimodal digital data, from omics and biomarkers to behaviour and lifestyle, contributing to the advancement of precision public health strategies across Europe.

I-P-D.09

Effectiveness and Behavioural Mechanisms of Physical Activity mHealth Interventions for Type 2 Diabetes Management: Meta-analysis

A. Willms¹, L. O'Malley¹, S. Liu¹

¹University of Victoria, Victoria, Canada

Purpose: 1) Evaluate the effectiveness of mHealth physical activity (PA) interventions in reducing HbA1c among adults with Type 2 Diabetes (T2D). 2) Examine key intervention components, including behaviour change techniques (BCT) and their ontologies to provide an understanding of how design and behavioural mechanisms influence intervention effectiveness.

Methods: Randomized controlled trials published in English from 2010–2025 were identified through four major databases and gray literature sources. Eligible studies included adults (≥ 18 years) with T2D using smartphone-based mHealth tools that incorporated a PA component and reported HbA1c outcomes. Random-effects meta-analyses (Hedges' g) were conducted to estimate pooled effects on HbA1c, with subgroup analyses examining BCTs and BCT ontologies.

Results: A systematic search conducted in June 2025 identified 27 independent studies. Random-effects meta-analysis showed that mHealth intervention groups achieved significantly greater reductions in HbA1c compared to control groups ($g = -0.35$, 95% CI = -0.45 to -0.24) with significant heterogeneity observed ($Q = 64.57$, $p < 0.05$). Subgroup analyses revealed that including the following BCT ontologies were associated with larger HbA1c improvements ($g \approx -0.23$ to -0.32), compared to other ontologies: goal directed, monitoring, social support, increase awareness of consequences, guide how to perform a behaviour, and associative learning. Specifically, interventions using 6-10 BCTs within these ontologies yielded greater effects ($g = -0.32$, 95% CI = -0.49 to -0.51), while those with fewer or more techniques were less effective.

Conclusion: These findings aimed to advance our understanding of how specific behavioural components influence the effectiveness of mHealth PA interventions for T2D management. Using BCT ontologies provided a more comprehensive framework for identifying intervention components, particularly when studies lacked explicit reporting. By analyzing intervention and app descriptions and available content, this approach allowed for more consistent classification of techniques across studies. Our results suggest that interventions incorporating goal setting, monitoring, social support, awareness of consequences, guidance on performing behaviours, and associative learning can effectively reduce HbA1c levels. Future research should prioritize clearer reporting and operationalization of behaviour change theories and techniques to strengthen reproducibility and optimize mHealth intervention design.

I-P-D.10

Step Count Changes before a Walking Challenge: Comparing New and Existing Activity Tracker Users

Z. Yin¹, D. Parra-Medina², J.L. Gay³, S. Buchholz⁴, Z. Mulla⁵, J.R. Thapa³, C. Dominguez⁶, K. Pal⁶, M. Sapargeldiyeva¹, G. Yza Muyna¹, J. Salinas⁶

¹University of Texas at San Antonio, Public Health, San Antonio, United States, ²University of Colorado Anschutz Medical Campus, Aurora, United States, ³University of Georgia, Athens, United States, ⁴Michigan State University, Lansing, United States, ⁵Texas Tech University Health Sciences Center, El Paso, United States, ⁶University of Texas at El Paso, El Paso, United States

D. E- & mHEALTH

Purpose: Reactivity—behavioral change resulting from awareness of being monitored—can influence physical activity levels when tracked by wearable trackers. This study examined whether participants enrolled in a walking challenge intervention study increased their daily step counts in the three weeks before the challenge’s start. We also assessed whether reactivity differed between individuals who were already using an Apple Watch and those newly provided with a Fitbit Inspire 3 Activity Tracker.

Methods: Study participants (N = 142) were enrolled in an ongoing clinical trial. Apple Watch users (n=71) were existing device owners, while Fitbit Tracker users who did not own a tracker received a Fitbit Tracker from the study. Daily step count data were collected from the three weeks before the challenge. A linear mixed effects model assessed changes in the weekly average daily steps for three weeks, including fixed effects for week, device type, and their interaction. Independent t-tests were used to examine the difference in step counts between devices at each week.

Results: Both user groups significantly increased their daily steps between Week 1 and Week 3. Apple Watch users increased by approximately 512 steps per week ($p < .001$), and Fitbit Tracker users by approximately 1,520 steps per week ($p < .001$). A significant interaction between device type and week ($p < .001$) indicated greater reactivity among Fitbit Tracker users. Mean daily steps rose from 7,113 (Apple Watch users) and 6,134 (Fitbit Tracker users) in Week 1 to 8,016 and 9,409, respectively, in Week 3. Across all participants, mean daily steps increased from 6,808 to 8,705. Fitbit Tracker users recorded significantly more steps than Apple Watch users by Week 3 ($p < .00001$).

Conclusion: Participants showed behavioral reactivity in the weeks preceding a walking challenge, with new Fitbit Tracker users exhibiting a steeper increase in activity than existing Apple Watch users. These findings emphasize the need to account for pre-intervention reactivity when interpreting physical activity outcomes in tracker-based studies.

I-P-D.11

Development of a Just-in-Time Adaptive Intervention to Reduce Glucose Excursions in Persons with Overweight/Obesity

C. Rethorst¹, B. Lim¹, S. Bruce², D. Dey², J. Szeszulski¹

¹Texas A&M Agrilife Research, Dallas, United States, ²Texas A&M University, College Station, United States

Purpose: Development of a just-in-time adaptive interventions (JITAI) requires identifying moments of opportunity for intervention, or “states of vulnerability” (i.e., moments at which an individual is at-risk for poor dietary behavior). Each state of vulnerability represents a decision point at which intervention delivery can be informed by tailoring variables. Continuous glucose monitors (CGMs) facilitate real-time, objective measurement of interstitial glucose. Glucose variability is primarily the result of postprandial glucose increases driven by meal composition, timing, and frequency, and has been identified to increase chronic disease risk in non-diabetic populations. CGMs, paired with other data sources, can provide insight into the time-varying factors that influence eating behavior. Machine learning can model these dynamic physiological and behavioral data to identify states of vulnerability. This presentation will describe the process by which we use machine learning to inform development of a JITAI to decrease glucose excursions, a measure of glucose variability.

Methods: Our approach leveraged existing data from 75 individuals with BMI ≥ 25 . In a 14-day observational study, participants wore a blinded CGM, and Fitbit Inspire 2, and received six daily ecological momentary assessments on affect, hunger, and boredom. We first developed a machine learning model to predict the likelihood of a glucose excursion. Next, we used cluster analysis to distinguish between different states of vulnerability and identify features of those unique states of vulnerability. Finally, we utilized an Intervention Mapping approach, informed by the clusters and feature importance, to develop tailored intervention messages.

Results: The machine learning model identified 634 moments of vulnerability. Cluster analysis revealed three clusters: Cluster 1 characterized by hunger and declining glucose levels, Cluster 2 characterized by increasing glucose, late in the evening (8pm or later), and no hunger; Cluster 3 characterized by stable glucose and evening (6pm or later). These clusters informed tailored messages targeting behavioral determinants congruent with specific states of vulnerability.

Conclusion: Identification of specific states of vulnerability can support the delivery of tailored JITAI. This approach aims to ensure that intervention support is matched to an individual’s specific state, which we hypothesize will lead to greater intervention efficacy and reduced habituation to intervention prompts.

I-P-D.12

Digital Dietary Assessment for All Ages: Usability of Traqq-Belgium in (Older) Adults

K. Cnudde¹, H. de Jong², D. Van Dyck¹, D. Lucassen²

¹Ghent University, Ghent, Belgium, ²Wageningen University & Research, Wageningen, Netherlands

Purpose: Accurate dietary assessment remains a challenge in nutrition research. Smartphone applications offer efficient and scalable solutions, but few have been adapted to local contexts or evaluated among older adults. To our knowledge, no validated, user-friendly apps tailored to the Flemish context exist. This study aims to (1) adapt Traqq, a Dutch-developed and validated dietary assessment app, to the Belgian (Flemish) context, and (2) evaluate its usability among older adults, an underrepresented group in digital health innovations.

Methods: Traqq was adapted by (1) developing a country-specific food list using the Belgian Food Composition Database, (2) incorporating Belgian portion sizes and product packaging, and (3) integrating and reviewing content with Belgian nutritionists. The app was evaluated in 130 healthy older adults (55–75 years). Participants recorded all food and beverage intake on four non-consecutive days within one week and completed the System Usability Scale (SUS) questionnaire afterwards, which includes 10 items rated on a 5-point Likert scale. SUS-scores range from 0-100, with >68 indicating above-average and >80 considered excellent usability. Mann-Whitney U tests were performed to compare SUS-scores based on sex, jobstatus, and prior experience with nutrition apps.

Results: In total, 130 older adults (68% women, 65.6±5.9 years, mean BMI 25.4±4.4 kg/m²) completed the study. Most participants were retired (72%). The majority were omnivores (88%) and 88% had no prior experience with nutrition apps. Mean self-reported energy intake was 1820 ± 574.6 kcal/day. Usability was above-average, with a mean SUS-score of 77.1 ± 16.0. Only 28.1% of participants reported that all consumed foods could be found in the food list. No significant differences in SUS-scores were found between men and women (p=0.486), professionally active and retired participants (p=0.996), and participants with or without prior experience with nutrition apps (p=0.157).

Conclusion: The high SUS-score indicates above-average usability among older adults, even for those without prior experience using nutrition apps. This highlights its potential as an accessible and user-friendly tool for dietary assessment in this population. Future research should focus on expanding the food list to improve completeness. This could improve reporting accuracy, user experience and strengthen the role of smartphone applications in nutrition research.

I-P-D.13

How Can Hard-to-reach Postpartum Migrant Women Be Recruited for Digital Health Interventions; Insights from the PRIMI Trial

A. Seiterö¹, M. Shirvanifar¹, M. Jubran Leksell¹, M. Rydfjord¹, B. Al-Saedi², A. Salah Ahmed¹, T. Gharakhani Bahar³, D. Berglind^{4,5,6}, H. Henriksson^{7,1}, V.H Ahlqvist^{8,9}, J. Wängdahl^{10,11,12}, U. Müssener¹, P. Henriksson¹

¹Linköping University, Department of Health, Medicine and Caring Sciences, Linköping, Sweden, ²Refugee Health Centre Region Östergötland, Norrköping, Sweden, ³Department of Obstetrics and Gynecology, Region Kalmar County, Kalmar, Sweden, ⁴Karolinska Institutet, Department of Global Public Health, Stockholm, Sweden, ⁵Region Stockholm, Centre for Epidemiology and Community Medicine, Stockholm, Sweden, ⁶Stockholm School of Economics, Center for Wellbeing, Welfare and Happiness, Stockholm, Sweden, ⁷Unit for Strategic Healthcare, Region Östergötland, Linköping, Sweden, ⁸Aarhus University, Department of Biomedicine, Aarhus, Denmark, ⁹Karolinska Institutet, Institute of Environmental Medicine, Stockholm, Sweden, ¹⁰Karolinska Institutet and Stockholm University, Aging Research Centre, Stockholm, Sweden, ¹¹Karolinska Institutet, Department of Neurobiology, Care Sciences, and Society, Stockholm, Sweden, ¹²Uppsala University, Department of Public Health and Caring Sciences, Uppsala, Sweden

Purpose: The PRIMI (Promoting Reproductive Health in Migrant Women) trial aims to evaluate the effectiveness of a smartphone app (the PRIMI app) on primary outcomes—diet quality and moderate-to-vigorous physical activity—and secondary outcomes, including health literacy, BMI, self-efficacy, and self-rated health, in first-generation migrant women after childbirth. The project can further provide insights and lessons learned regarding the recruitment of a hard-to-reach population for a digital intervention targeting physical activity and diet quality.

Methods: The PRIMI app provides support for physical activity, healthy diet, and health literacy using behavior change strategies such as goal setting, self-monitoring, and feedback, with content delivered via text, audio-files, and video in four languages: Arabic, Somali, English, and Swedish. A two-arm (1:1) randomized controlled trial will assess the

D. E- & mHEALTH

6-month effectiveness of the PRIMI app compared with standard care, such as parental guidance and support within child health care. Eligible participants are first-generation migrant women ($n = 200$) who have given birth within the past 6 months, are aged ≥ 18 years, and prefer to receive health-related information in any of the provided languages. Participants will be recruited through health care services in Sweden. The recruitment strategy includes follow-ups (e.g. visits or phone calls) between the research team and professionals (e.g. nurses) at the participating health care services ($n = 20$) every two months. These follow-ups involve dialogues focusing on professionals' experiences, ideas, and suggestions for creating favorable conditions for recruiting women, thereby facilitating mutual learning to enhance the recruitment of this underrepresented and marginalized group.

Results: Recruitment began in September 2025 and is expected to continue for at least one year. While results for the primary and secondary outcomes are anticipated in 2027, preliminary findings on recruitment insights and lessons learned will be available for presentation in May 2026.

Conclusion: As most digital interventions promoting physical activity and healthy diet are insufficiently tailored for migrant populations, the PRIMI project makes a significant contribution by generating both methodological and practical insights for future interventions targeting underrepresented groups, supporting equitable access to behavior change interventions focused on physical activity and healthy diet.

I-P-D.14

A Digital Physical Activity and Healthy Diet Intervention for People around Retirement Age: Results from the SO-NUTS Feasibility Study

J.D. Schoufour¹, N. Toussaint¹, T. Vágnerová², E. Klaassen¹, D. Bossen¹, M. Oey³, S. Kramer³, P. Collazo Castiñeira⁴, L. Reiter⁵, D. Eglseer⁵, Y. Boirie⁶, T. Voortman⁷, A. Cruz-Jentoft⁸, S. Ben Allouch³, E. Topinkova², P. Weijs¹

¹Amsterdam University of Applied Sciences, Faculty of Health, Sport and Physical Activity, Amsterdam, Netherlands,

²Charles University and General University Hospital, Prague, Czech Republic, ³Amsterdam University of Applied Sciences, Amsterdam, Netherlands, ⁴Servicio de Geriatria, Hospital Universitario Ramon y Cajal (IRYCIS), Madrid, Spain, ⁵Medical University of Graz, Institute of Nursing Scienc, Graz, Austria, ⁶Clermont Auvergne University, Clermont-Ferrand, France, ⁷Erasmus MC, Department of Internal Medicine, Rotterdam, Netherlands, ⁸Hospital Universitario Ramon y Cajal (IRYCIS), Servicio de Geriatria, Madrid, Spain

Purpose: Adopting healthier lifestyle behaviours during the transition to retirement is challenging. During this phase, changes in daily routines can accelerate weight gain and muscle loss, increasing the risk of sarcopenic obesity—a condition characterized by the coexistence of excess adiposity and reduced muscle mass and function. To prevent sarcopenic obesity, we developed the SO-NUTS mobile application to empower individuals around retirement to lose weight while preserving muscle mass and function. This study aimed to evaluate the feasibility of the SO-NUTS application and explore its potential effects on sarcopenic obesity-related outcomes among healthy, overweight adults around retirement.

Methods: We conducted a 6-week, one-arm feasibility study across four European countries among 121 participants who were either approaching retirement (<3 years) or recently retired (<5 years) with a BMI >27 . Participants attended baseline and 6-week follow-up visits at local research institutes and used the co-designed SO-NUTS mobile application, which integrates evidence-based behaviour-change techniques to improve diet and physical activity. Feasibility outcomes included user experience (System Usability Scale, SUS) and exploratory outcomes included dietary quality, physical activity (steps p/d), body composition (BMI, fat mass, fat-free mass), physical performance (grip strength, gait speed, 5×chair stand), and quality of life. Data were analysed descriptively and with paired-sample t-tests.

Results: 121 participants were enrolled and 106 finished the study: Netherlands ($n=25$), Czech Republic ($n=70$), Austria ($n=13$), and Spain ($n=13$). The mean age was 67 years ($SD=7$); 77% were female. Based on the SUS, 20% rated usability as good or excellent, 42% as moderate, and 38% as poor, with an average score of 53. Compared with baseline, participants significantly increased their steps per day (mean change=646, $SD=3014$; $p=0.046$), reduced BMI (-0.50 , $SD=0.99$; $p<0.001$), reduced fat mass (-0.73 kg, $SD=2.01$, $p<0.001$), and improved quality of life (mean change=3.0, $SD=1.23$; $p=0.023$). No significant changes were observed in other outcomes.

Conclusion: Although usability ratings varied, improvements in physical activity, adiposity, and quality of life suggest that SO-NUTS is promising for supporting lifestyle change. These findings highlight the potential of digital technology to effectively deliver evidence-based behaviour-change techniques aimed at preventing sarcopenic obesity among adults in the transition to retirement.

D. E- & mHEALTH

I-P-D.15

Use and Perceived Barriers to Mobile Health Apps among Cancer Survivors: Results from a Cross-sectional Survey

R.M. Benzo¹, M. Tetrack¹, J. Fisher²

¹The Ohio State University, Internal Medicine, Columbus, United States, ²James Cancer Hospital at The Ohio State University, Columbus, United States

Purpose: Mobile health (mHealth) applications are increasingly used to support behavior change and self-management among cancer, yet adoption is not fully understood. This study examined patterns of smartphone and mHealth app use, common reasons for use and nonuse, and factors associated with mHealth app engagement among cancer survivors.

Methods: Data were drawn from a cross-sectional survey of 953 cancer survivors who responded to questions about smartphone ownership and mHealth app use. Descriptive statistics summarized ownership, app use, specific apps used, reasons for use, and barriers. Logistic regression analyses examined predictors of current mHealth app use, including demographic factors, fitness tracker ownership, and reported barriers.

Results: Among 953 respondents, 913 (95.8%) owned a smartphone. Of 906 participants, 373 (41.2%) reported currently using mHealth apps. Commonly used apps included Apple Fitness (42.6%), MyFitnessPal (19.6%), and Fitbit (16.1%). The most frequent reasons for use were activity tracking (84.5%), heart rate tracking (42.1%), goal setting/progress tracking (34.9%), sleep tracking (30.3%), and motivation/reminders (28.7%).

Among current users, barriers included cost (22.8%), information overload (19.6%), lack of motivation (16.6%), limited technical skills (13.7%), and concerns about validity (13.1%). Among non app users (n=533), the most common barriers were lack of technical skills (26.1%), cost (26.1%), information overload (23.5%), lack of motivation (15.0%), belief that an app is unnecessary (14.3%), privacy concerns (12.9%), poor usability (11.3%), concerns about validity (10.9%), and preference for traditional methods (10.1%).

Multivariate analysis showed that fitness tracker ownership was strongly associated with mHealth app use (OR = 5.21; 95% CI: 3.54–7.65), while increasing age (OR = 0.98 per year; 95% CI: 0.97–1.00) and privacy concerns (OR = 0.57; 95% CI: 0.32–1.01) were linked to lower odds of use. Of 913 smartphone owners, 820 (89.8%) were willing to share mHealth data with researchers, and 654 (68.6%) wanted to learn how apps can support health management.

Conclusion: Nearly all participants owned smartphones, but fewer than half used mHealth apps. Cost, information overload, and privacy concerns were the most prevalent barriers. High willingness to share data and interest in mHealth education highlight opportunities for tailored digital literacy and engagement strategies to promote app adoption in cancer.

I-P-D.16

Integrating Diet Data Collection in Clinic: Findings from the Study of nUtrition in Postpartum and EaRly Life (SUPER)

M. Burgermaster¹, U. Shamim¹, M. Rosenthal¹

¹University of Texas at Austin, Austin, United States

Purpose: Pregnancy is a prime opportunity for behavioral nutrition interventions. In addition to the influence of prenatal diet on maternal and child outcomes, pregnant patients are often especially attuned to nutritional guidance. Most pregnant patients have regular prenatal appointments, making maternal-fetal medicine clinics an ideal site for nutrition risk assessment and behavioral nutrition interventions. However, the lack of diet data in the clinical setting limits the potential of these interventions. Therefore, we assessed the feasibility of collecting diet data with the Automated Self-Administered 24-Hour Dietary Assessment Tool (ASA24) during routine ultrasound appointments.

Methods: We collaborated with physicians, nurses, and sonographers at our partnering clinic to develop a diet data collection workflow. Then, we recruited English and Spanish-speaking adult patients who were 18–32 weeks pregnant without fetal abnormalities. After obtaining consent, bilingual research assistants demonstrated ASA24 and guided participants to complete a recall on a study tablet. Participants were asked to complete a second ASA24 on their own device at home, receiving US\$20 at each time point. We collected field notes and ASA24 usage log data to describe consent rates, ASA24 completion, recall language, and time to complete the recall. Valid recalls contained complete data and no calorie outliers (i.e., <300 kcals or $\geq 1.5 \times \text{IQR}$ above the median).

Results: Of 206 patients approached, 152 (74%) consented to participate (mean age=29+/-6 years; 99% women; 64%

D. E- & mHEALTH

Latinx), translating to a rate of 2.8 patients per research assistant per half day. 141 (93%) completed a valid recall (123 in clinic and 18 at home), in English (64%) or Spanish (36%). The mean time to complete ASA24 in clinic was 16+/-7 minutes. 113 (75%) completed a second ASA24 at home.

Conclusion: We demonstrated the feasibility of collecting diet data with ASA24 during routine prenatal ultrasound appointments, addressing a lack of diet data available to inform clinic-based nutrition interventions. Our implementation, which employed dedicated research staff and participant incentives, yielded high consent and completion rates across a diverse population and provides an initial framework for operationalizing diet data collection in clinical settings. This lays the groundwork for future models for integrating dietary assessment into prenatal care.

I-P-D.17

Examining the Long-term Impact of a Gamified mHealth App: An 18-month Prospective Cohort Study

Y. Genaidy¹, M. Mitchell¹, E. Bloom²

¹Western University, Kinesiology, London, Canada, ²WayBetter Inc., New York City, United States

Purpose: This study aimed to evaluate long-term user engagement and behavioral outcomes associated with the WayBetter mobile health (mHealth) app, which integrates gamification, coaching, and financial incentives to promote physical activity (PA) and healthy eating. It explored differences in app perceptions and health behaviors among different categories of users; an innovative follow-up extending evidence on mHealth sustainability beyond 12 months.

Methods: We initially recruited a cohort of 1,178 new WayBetter users starting a free trial (Nov 2023-Jan 2024), who completed a baseline survey (i.e. sociodemographics, health behaviors). In June 2025, we sent a follow-up survey to the same cohort, which assessed app opinions (i.e., Mobile Application Rating Scale) as well as current and previous (i.e., “while actively using WayBetter”) self-reported health behaviors. Follow-up survey respondents were classified into three groups: (1) Never members (free trial only), (2) Former members, and (3) Current members. Group differences were examined using χ^2 tests and ordinal logistic regression with covariates included in the model to adjust for baseline differences.

Results: One hundred and fifty-seven participants (Mean age: 40.83 years; % female: 92.09; 13.33% of initial cohort) responded to the follow-up survey (Never, n=60; Former, n=55; Current, n=42). Current members rated app ease-of-use more positively compared to Former and Never members ($p=.007$, $V=.264$). Current members were significantly more likely to agree that the app encouraged help-seeking ($p=.025$, $V=.276$) and that they would recommend it to others ($p=.017$, $V=.290$). After adjusting for baseline differences in PA levels, former members at follow up were more likely to report higher levels of vigorous PA compared to Current members ($p=.044$) and Never members were more likely to report higher levels of moderate PA compared to Current members ($p=0.024$). No groups differences in nutrition were observed ($p>.05$).

Conclusion: Eighteen months after initiating a 7-day free trial, as expected, Current members held more positive app opinions than Former and Never members. On the other hand, and surprisingly, Current members self-reported less PA than the other two groups, after adjusting for baseline PA differences. This disparate finding may be because Current members had less room to improve (‘ceiling effect’) and warrants further investigation.

I-P-D.18

Development of a Visualizing Nutrition Labeling System for Food and Meals

Y. Caballero¹, Y. Kawashima¹, A. Ushiwata², T. Akatsuka³

¹Utsunomiya University, Cooperative Faculty of Education, Utsunomiya, Japan, ²Kitasato University, Department of Clinical Medicine (Biostatistics), School of Pharmacy, Tokyo, Japan, ³Tokyo Gakugei University, Faculty of Education, Tokyo, Japan

Purpose: Accurately assessing nutrient intake from food and meals is crucial for preventing obesity and non-communicable diseases and maintaining health. This study developed a novel nutrition labeling system that uses pictures to convey the nutritional characteristics of foods and dishes and to evaluate the understandability of the system for refinement.

Methods: A home page was programmed allowing the user to select from 19 food or dishes, which then generated a triangle representing energy balance picture and flower representing nutrition balance. The flower was programmed

D. E- & mHEALTH

to visualize 12 nutrient values and the degree of sufficiency for the adult needed per meal, such as energy, energy-producing nutrients such as protein, three vitamins, and four minerals, based on nutrient-rich food (NRF9.3). A paper or web survey of adults was conducted between June and August 2025. The questionnaire included 9 questions, including 4-point scale questions on understandability and interest in the use for learning, a 10-point satisfaction scale (from 0 to 10 meant from “very unsatisfied” to “very satisfied”), and an open-ended feedback question.

Results: There were 77 participants. Of the participants, 98.7% found the tool very interesting (59.2%) or interesting to some extent (39.5%) and 98.7% answered that it was easy to understand (51.9%) or understandable to some extent (46.8%). The mean score for satisfaction with the system was 8.16. Open-ended feedback suggested that values of the ideal intake should be shown in the picture, data entry should be made easier (such as using a camera or the Internet), and personalized programs should be developed.

Conclusion: The novel visualized nutrition labeling made it easy to understand the nutritional characteristics of food and meals and showed potential for supporting diet management and nutrition education. The free answers suggested that further improvement and practical application were needed.

I-P-D.19

Evaluation of the NHS Active 10 Walking App Intervention through Time-series Analysis in 201,688 Individuals

D. Yerrakalva¹, S. Hajna², S. Brage³, S. Griffin³

¹University of Cambridge, Primary Care and Public Health, Cambridge, United Kingdom, ²Brock University, St Catharines, Canada, ³University of Cambridge, Cambridge, United Kingdom

Purpose: Despite widespread interest in integrating mobile health apps into primary care to prevent and manage physical inactivity-related health conditions, the effectiveness of these apps remains unclear. We aimed to quantify the effects of the NHS Active 10 app on brisk and non-brisk walking in a UK population between July 2021 and January 2024.

Methods: Design: The NHS Active 10 smartphone app was designed, promoted, and delivered through Public Health England. We conducted a single-group interrupted time-series analysis on individual-level data from users of the Active 10 app, comparing brisk and non-brisk walking levels (min/day) before and after users downloaded the app.

Participants & Setting: All UK smartphone users were eligible, and self-selected by download of the Active 10 app. Included participants downloaded the app and had 5 days of pre-download walking data (extracted from the user's device by the app at the time of download) and 28 days of post-download walking data available.

Intervention: The intervention consisted of a smartphone app centred on goal setting and self-monitoring of walking, optional use of widget notifications, and used for at least 28 days.

Main outcomes: These were post-download change on day 1 and post-download trend change in brisk and non-brisk walking levels (mins/day).

Results: Among Active 10 users ($n=201,688$; 51.4 ± 14.4 years; 75.4% women) brisk and non-brisk walking increased by 9.0 (95% confidence interval (CI) 8.9, 9.1; 73% above baseline) and 2.6 min/day (95% CI 2.4, 2.8; 9% above baseline), respectively, on the day of app download. Post-download, brisk and non-brisk walking decreased by 0.15 (95% CI -0.17, -0.13) and 0.06 (95% CI -0.08, -0.03) min/day/month, respectively, but remained above baseline.

Conclusion: Our findings suggest that large-scale population-level intervention tools such as the Active 10 app may be effective for facilitating clinically important increases in brisk walking among adults living in the UK. App engagement may contribute to the app's effectiveness.

I-P-D.21

Impact of Health-related Social Media Use on Exercise: A Cross-sectional Study Using Data from HINTS7

A. Schymiczek Larangeira Almeida¹, A. Shashank Mannava¹, D.A. Soto¹, O. Amaral de Andrade Leão¹

¹University of Illinois Urbana-Champaign, Health & Kinesiology, Champaign, United States

Purpose: The study aimed to assess the association between the frequency of health-related social media use among adults and exercise. We hypothesized that participants with higher health-related social media use would also have higher exercise levels. The association between social media use and exercise has been documented in the scientific literature. However, limited research has examined whether health-related social media use is associated with exercise.

D. E- & mHEALTH

Methods: This cross-sectional study was a secondary data analysis of the seventh edition of the Health Information National Trends Survey (HINTS7, n=7,278). The categorical variable of health-related social media use was designated as the exposure variable, categorized as never, infrequent, and frequent use. The continuous variable of weekly minutes of exercise was utilized as the outcome. Age, birth sex, ethnicity, educational level, feelings related to income, and weekly work hours were included as confounders. Linear regression models were run to evaluate the unadjusted and adjusted associations. The results are presented as regression coefficients (β) with the highest frequency of social media use set as the reference category.

Results: Frequent use of health-related social media was observed in 14.9% of participants, while infrequent use was identified in 49.3% of the sample. No use was reported by 35.8% of participants. The mean weekly moderate-intensity exercise was 182.9 minutes (SD=328.9). In the adjusted model, participants who used health-related social media infrequently had, on average, 13.4 fewer minutes (95% CI: -37.9 to 11.1) of weekly exercise than those who used it frequently ($p = 0.284$). Individuals who reported no health-related social media use had an average of 2.5 fewer minutes (95% CI: -29.5 to 24.5) of weekly exercise than the reference group with frequent use ($p = 0.855$).

Conclusion: Despite the direction of association suggesting that health-related social media use may benefit exercise levels, our findings suggest no statistically significant association between those variables. The use of health-related social media to improve exercise engagement shows promise. However, further studies are needed to better understand how to use this tool effectively to promote measurable changes in health-related outcomes.

I-P-D.22

Associations between Digital Health Engagement and Physical Activity among Women in Resource-limited Urban Communities: Data from the Step It Up Community-engaged, Digital Health Intervention

M.R. Andrews¹, M.A. Cintron¹, M.A. Pita¹, H.A. Tarfa¹, F. Osei Baah², S.T. Reynolds¹, S.R. Hicks¹, D. Sandler¹, S.J. Lopez de Leon¹, J.E. Seo¹, S. Sharda¹, M. Heist³, B. Frew³, A. Dave¹, B. Collins⁴, S. Deguzman¹, E.M. Aquino Peterson¹, L.R. Ortiz-Whittingham¹, A.S. Baez¹, M.J. Williams¹, A. Saurabh¹, L. Mendelsohn¹, M. Marah¹, A. Wells¹, J.F. Troendle¹, Y. Baumer¹, T. Dodge⁵, T.M. Powell-Wiley¹

¹National Institutes of Health, Bethesda, United States, ²Emory University, Atlanta, United States, ³University of North Carolina-Chapel Hill, Chapel Hill, United States, ⁴Indian Health Service, Livingston, United States, ⁵The George Washington University, Washington, United States

Purpose: Physical activity (PA) reduces cardiovascular disease risk; however, few studies have developed place-tailored digital health interventions to increase PA among resource-limited women in urban areas. Therefore, we sought to explore how engagement with a digital health application (app) is associated with PA in resource-limited communities and how psychosocial factors may modify these relationships.

Methods: African American women with overweight/obesity were recruited from under-resourced communities in the Washington, DC metropolitan area to participate in the six-month *Step It Up* intervention. Participants received a Fitbit Charge 2 device to track PA and downloaded the *Step It Up* digital health app to receive health promoting content, self-monitoring tools, and motivational messaging promoting PA. Engagement was measured by whether a participant used the educational modules, goal-setting tools, or completed ecologic-momentary assessments. We examined associations between overall app engagement and PA (in steps/day) and whether these associations were modified by social isolation and chronic stress measured by validated questionnaires. Mixed-effects models accounted for repeated measures within participants over the six-month intervention period, allowing examination of within- and between-person relationships. All models were adjusted for age, BMI, and socioeconomic status.

Results: Participants (n=151) had a mean age of 57±11 years, a BMI of 36.75 ± 7 kg/m², and a mean income of \$69,731 ± 31,454. App engagement was associated with 149 more steps/day ($p < 0.001$), with significant interactions between engagement and both social isolation ($\beta = -67.89$, $p = 0.01$) and chronic stress ($\beta = 5.46$, $p = 0.01$). With higher social isolation, greater engagement associated with less PA, whereas higher chronic stress, greater engagement associated with greater PA.

Conclusion: Engagement with a community-tailored, digital health application was positively associated with PA during the *Step It Up* intervention among African American women living in resource-limited Washington, D.C. communities. However, these associations varied by psychosocial factors. Future work should examine additional contextual factors that may modify these associations and assess whether tailored-to-place messaging may impact PA.

Optimal Physical Recovery after Hospitalization for Patients after Oncological Surgery (OPRAH): A Multicenter, Single-blind, Randomized Controlled Trial

M.E. de Leeuw¹, C. van Westerhuis², W.M. Charmant¹, E. Geleijn¹, H. Kruizenga³, J.WR Twisk⁴, C. Dickhoff⁵, M.I. van Berge Henegouwen⁶, M.G Besselink⁶, J.E Erdmann⁶, V. de Groot¹, M. van der Schaaf⁷, M. van der Leeden¹

¹Amsterdam UMC, Location VUmc, Rehabilitation Medicine, Amsterdam, Netherlands, ²Amsterdam University of Applied Sciences, School of Physiotherapy, Amsterdam, Netherlands, ³Amsterdam UMC, Location VUmc, Nutrition and Dietetics, Amsterdam, Netherlands, ⁴Amsterdam UMC, Location VUmc, Epidemiology and Data Science, Amsterdam, Netherlands, ⁵Amsterdam UMC, Location VUmc, Cardiothoracic Surgery, Amsterdam, Netherlands, ⁶Amsterdam UMC, Location University of Amsterdam, Surgery, Amsterdam, Netherlands, ⁷Amsterdam UMC, Location University of Amsterdam, Rehabilitation Medicine, Amsterdam, Netherlands

Purpose: Following major oncological surgery, patients may prevent muscle mass loss and postoperative decline in physical functioning by increasing their physical activity levels and meeting protein intake requirements. However, effective post-discharge interventions to reach this aim are limited. Blended interventions, combining digital tools, such as smartphone apps and activity trackers, with personalized coaching, offer promising solutions to enhance patient self-management. Therefore, we developed the blended Optimal Physical Recovery After Hospitalization (OPRAH) intervention. The purpose was to evaluate the efficacy of the OPRAH intervention to improve physical activity and protein intake after hospital discharge on recovery of physical functioning in patients after oncological gastrointestinal and pulmonary surgery.

Methods: A multicenter single-blinded randomized controlled trial was performed in adults undergoing curative intent oncological gastrointestinal and pulmonary surgery. Patients were assigned to usual care (control) or usual care plus a three-month post-discharge intervention comprising a smartphone app, activity tracker, and remote coaching from a physiotherapist and dietitian. Assessments were conducted preoperatively and at one, four and eight weeks, and three- and six-months post-discharge. The primary outcome was recovery in physical functioning, measured using the CAT PROMIS Physical Functioning questionnaire. The most important secondary outcome was physical activity.

Results: Overall, 163 patients were included (73 intervention, 90 control). An overall intervention effect on physical functioning was found in favour of the intervention group (difference 1.7; $p=0.03$). Physical activity levels were also significantly higher in the intervention group (difference = 12.9; $p=0.01$). Additional benefits were observed in protein intake, fatigue, pain, participation, self-efficacy, global perceived effect, and handgrip strength. No significant effects were noted for energy intake, lean body mass, physical performance, and readmission rates.

Conclusion: The OPRAH intervention – combining self-monitoring with remote coaching by a physiotherapist and dietitian to promote post-discharge physical activity and protein intake – effectively enhances recovery in physical functioning after curative intent oncological gastrointestinal and pulmonary surgery. Patients were more physically active, met their protein intake requirements more often and experienced less fatigue. Taken together, these findings suggest that the OPRAH intervention supports recovery while enabling patients to take a more active role in their own postoperative rehabilitation.

I-P-D.24

Adherence to Just-in-time Prompts for Interrupting Sitting and Increasing Walking Pace in Adults with Prediabetes and Type 2 Diabetes: An Ecological Momentary Assessment Study

I. Maes¹, D. Van Dyck¹, J. Novak², J. Kuhnova³, M. Janek², S. Elavsky⁴, M. Steffl², R. Cimlér³, N. Kral⁵, M. Pfeiferova⁵, B. Seifert⁵, T. Yates^{6,7}, T. Harris⁸, T. Vetrovsky^{5,9}

¹Ghent University, Department of Movement and Sports Sciences, Ghent, Belgium, ²Charles University, Prague, Czech Republic, ³University of Hradec Kralove, Hradec Kralove, Czech Republic, ⁴University of Ostrava, Ostrava, Czech Republic, ⁵Institute of General Practice, Charles University, Prague, Czech Republic, ⁶Institute for Social Marketing and Health, University of Stirling, Stirling, United Kingdom, ⁷Diabetes Research Centre, University of Leicester, Leicester, United Kingdom, ⁸City St George's University of London, London, United Kingdom, ⁹Faculty of Physical Education and Sport, Charles University, Prague, Czech Republic

D. E- & mHEALTH

Purpose: Interrupting prolonged sitting and increasing physical activity (PA) are essential for managing prediabetes and type 2 diabetes, yet these behavioral changes remain difficult to achieve. The ENERGISED trial used mHealth technologies to deliver occasional just-in-time prompts suggesting either a sitting interruption or an increased walking pace. This study examined the associations between self-reported adherence to these prompts and fatigue, stress, and pain, using ecological momentary assessment (EMA).

Methods: Patients in the intervention arm of the ENERGISED trial received just-in-time prompts when they had been sedentary for ≥ 30 minutes or walking for ≥ 5 minutes. Fifteen minutes later, an EMA survey was delivered via the HealthReact application (maximum once every other day) assessing adherence, reasons for non-adherence, and fatigue, stress, and pain levels (0 – 10 Likert scales). A Fitbit tracker monitored PA. Multilevel logistic mixed-effects models were used to analyze subjective adherence and its associations with fatigue, stress, and pain. Hurdle models will be applied to examine the associations between Fitbit-derived PA and fatigue, stress, and pain, with these findings to be presented at the conference.

Results: Forty-one patients participated for a median of 252 days. They received 2125 sitting-interruption and 1712 walking-pace prompts; 949 and 729, respectively, were followed by an EMA survey, of which 394 (42%) and 338 (46%) were completed. Sitting was interrupted after 26% of prompts; the most frequent barrier was concurrent activities such as driving or focused work (44%). Walking pace increased after 28% of prompts; the most common reason for non-adherence was that walking had already stopped (39%). Higher fatigue (OR 0.983, 95% CI 0.969–0.997, $p = 0.019$) and stress (OR 0.979, 95% CI 0.961–0.997, $p = 0.026$) reduced the odds of increasing walking pace, while pain showed no effect. No associations were found for sitting-interruption adherence.

Conclusion: Adherence to just-in-time suggestions to interrupt sitting or increase walking pace was modest. Inappropriate timing, prompts delivered during incompatible activities or after walking had stopped, emerged as a key limitation. Improving trigger algorithms to identify receptive and feasible moments may enhance the effectiveness of mHealth-supported behaviour change interventions.

I-P-D.25

A Theory-informed Mobile Health Application to Promote Physical Activity: The Planning and Design, Iterative Prototyping, and Development of a Minimum Viable Product

H. Hollman¹, W. Sui², H. Zhang¹, R. Sayar³, S. Courtnall¹, H. La⁴, A. Heck⁵, A. Lithopoulos⁶, S. Grant¹, R.E. Rhodes¹

¹University of Victoria, School of Exercise Science, Physical & Health Education, Victoria, Canada, ²London Health Sciences Centre Research Institute, London, Canada, ³Komak Robotics, Vancouver, Canada, ⁴University of Victoria, School of Exercise Science, Physical, & Health Education, Victoria, Canada, ⁵University of British Columbia, Faculty of Land and Food Systems, Vancouver, Canada, ⁶University of Saskatchewan, School of Rehabilitation Science, Saskatoon, Canada

Purpose: Mobile health (mHealth) applications (apps) are attractive tools for physical activity (PA) behaviour change interventions because a large proportion of the global population owns a smartphone and checks it daily. Although many PA promotion apps are available, few are effective beyond three months and the majority are neither evidence-based nor grounded in behaviour change theory. The purpose of this study was to develop a PA promotion mHealth app, guided by an intervention development framework that integrates behavioural theory (the Multi-Process Action Control Framework), up-to-date mHealth app research, a pedagogical framework, and expert consensus.

Methods: The mHealth app development process consisted of three phases. Phase 1 Planning and Design involved an iterative expert panel and literature review to determine app needs. The expert panel included a theory team ($n = 10$ adult members of a university lab) and an app development team ($n = 2$ adult members of a second university lab). Phase 2 Iterative Prototyping involved developing a first prototype through a series of structured, iterative consensus building sessions among the theory team and modified product presentations from the app development team. Phase 3 Minimum Viable Product (MVP) involved two members of the expert panel developing an MVP with two rounds of feedback from the lab director.

Results: Phase 1 findings revealed key desired features of multiple choice quizzes, a PA affect slide bar, graphs and figures for education delivery, self-guided emotion-regulation visualization videos, grab-and-go activities, goal-setting, and PA self-monitoring. Phase 2 iterative prototype feedback informed content text reduction and an updated pedagogical framework (Bridge-In, Outcomes, Pre-Assessment, Presentation of New Material, Practice and Participation, Post-Assessment, and Summary). Additionally, finalization of app features included video embedment, quiz cards, survey cards, and step-count tracking from pre-existing smartphone apps (e.g., Apple Health). Phase 3 feedback resulted in image load optimization, a table of lesson mechanisms of action, and the addition of pre- and post-activities, learning outcomes, and summary cards to each lesson.

D. E- & mHEALTH

Conclusion: A theory-informed PA mHealth app MVP was developed that includes a pedagogically-derived lesson plan, embedded videos, interactive quizzes and surveys, and step-count tracking. Future studies will evaluate the feasibility and efficacy of the MVP.

I-P-D.26

Validation of an Augmented Reality Tool for Real-time Smartphone-based Exercise Repetition Counting

A. Sadghian¹, M. Mitchell¹

¹Western University, Kinesiology, London, Canada

Purpose: Resistance training (RT) self-monitoring can support behaviour change, yet most consumer RT tracking tools have limited real-world validation, especially for live repetition counting. This study evaluated the practical validity of a smartphone-based augmented reality (AR) repetition-counting tool against human counting, and examined whether accuracy is maintained across realistic conditions relevant to self-monitoring (multiple exercises, clothing that may occlude landmarks, and different adult groups). We hypothesized the AR tool would be equivalent to manual counting within a pragmatic margin of ± 1 repetition per set.

Methods: Cross-sectional practical validation study (planned $n=26$: 13 students, 13 office workers). Participants complete 4 bodyweight exercises (squat, sit-up, push-up/knee push-up, high knees), performing 10 consecutive repetitions in two clothing conditions: (1) typical athletic attire and (2) loose long-sleeve top and long pants. AR rep counts are recorded live on a smartphone while sessions are video-recorded for two-rater manual counting (criterion = mean). Primary analyses include equivalence testing (paired TOST, bounds ± 1 rep, 90% CI), plus agreement indices (mean bias, MAE, and limits of agreement). Mixed-effects models examine clothing and group effects.

Results: In the completed student cohort (13 students; 104 sets), manual counting reliability was high (96.2% exact agreement; ICC(2,1)=0.95, 95% CI 0.93–0.97). Relative to the manual mean, the AR tool showed minimal bias (mean difference=0.03 reps; SD=1.60) and low typical error (MAE=0.59 reps/set). Overall, 88.5% of sets were within ± 1 rep and 96.2% within ± 2 reps. Equivalence within ± 1 rep was supported (90% CI –0.23 to 0.29; both one-sided tests $p<.001$).

Conclusion: These results provide practical evidence that live smartphone AR repetition counting can approximate human counting closely enough to function as a scalable RT self-monitoring method in behaviour-change interventions. Ongoing data collection will determine whether performance is robust across exercises, clothing occlusion, and an older working-adult cohort, informing when AR self-monitoring is appropriate and when refinement or user guidance is needed.

I-P-D.27

Criterion Validity and Transparency in Wrist Accelerometry for 24-hour Movement Behaviour Analysis: A LABDA Scoping Review, Meta-analytical Summary, Reporting Checklist, and Web Application

M.J. Theophilus¹, A.P Kingsnorth¹, L. Sherar¹, M.J. ChinAPaw^{2,3}, D.W Esliger^{1,4,5}

¹Loughborough University, School of Sport, Exercise and Health Sciences, Loughborough, United Kingdom, ²Vrije Universiteit Amsterdam, Department of Public and Occupational Health, Amsterdam University Medical Center, Amsterdam, Netherlands, ³Amsterdam Public Health Research Institute, Health Behaviours and Chronic Diseases and Methodology, Amsterdam, Netherlands, ⁴NIHR Leicester Biomedical Research Centre, Leicester, United Kingdom, ⁵Nottingham University Hospitals NHS Trust, HealthTech Research Centre for Rehabilitation, Nottingham, United Kingdom

Purpose: Global surveillance of physical activity, sedentary behaviour, and sleep (24-hour movement behaviours), still relies on self-report. Wrist accelerometry provide continuous monitoring of these behaviours but adoption is limited by inconsistent transparency and comparability. This scoping review aimed to evaluate criterion validity and improve the reproducibility and comparability of methods using high-resolution wrist-worn accelerometer data for assessing 24-hour movement behaviours.

Methods: Five databases were searched (8 August 2024). Inclusion required peer-reviewed studies with participants aged ≥ 3 years using high-resolution wrist accelerometry to classify physical activity intensity against indirect calorimetry, activity type against direct or video observation, sleep-wake against polysomnography, or energy

D. E- & mHEALTH

expenditure against doubly labelled water or indirect calorimetry. End-to-end processing pipelines were mapped to identify reporting gaps and inform transparent reporting guidance. Criterion validity was evaluated using participant-weighted random-effects meta-regression overall and by behaviour domain and contrasted by model complexity (traditional vs non-traditional). Risk of bias was appraised using QUADAS-2.

Results: A total of 137 studies contributed 272 criterion validations. Major reporting gaps included accelerometer sensor specifications, on-board processing, signal quality control, participant ethnicity, and confusion matrices with event counts. Overall pooled classification performance was F1 84.2% (N = 4,892), sensitivity 90.4% (N = 6,968), and specificity 79.3% (N = 6,845). Domain-specific pooled F1 was 75.5% for activity intensity (N = 933), 85.4% for activity type (N = 1,071), and 86.4% for sleep-wake (N = 2,888). Energy expenditure estimation had pooled mean absolute percentage error 22.6% (N = 573). Non-traditional methods outperformed traditional methods overall on F1 by 10.1% ($p < 0.001$), with larger gains for activity intensity (25.5%, $p < 0.001$) and activity type (32.9%, $p < 0.01$), but were comparable for sleep-wake and energy expenditure.

Conclusion: Wrist accelerometry demonstrates strong pooled classification performance for 24-hour movement behaviour assessment when compared to criterion methods, but persistent reporting gaps impede reproducibility and comparability. This study provides a comprehensive comparison of wrist accelerometry-based methods and presents two applied outputs to support transparent reporting and evidence-based selection: TRAC-MOVE, a 15-item methods checklist, and SCOPE-MOVE, an interactive evidence explorer with built-in analytics used in this study.

II-P-D.01

Assessing the Feasibility and Usability of DESI-heart: A Conversational Agent-based Self-care Intervention for People with Cardiovascular Disease - A Pilot Study

A.T. Sebastian¹, P. Jansons¹, R. Maddison¹

¹Deakin University, Institute for Physical Activity and Nutrition, Melbourne, Australia

Purpose: Cardiovascular diseases (CVDs) are a leading cause of illness and death globally and in Australia. Although self-care is essential for managing CVDs, individuals often face barriers such as complex regimens, limited health literacy, and a lack of culturally appropriate support. To overcome these barriers, conversational agents (CAs) provide AI-driven, voice-based support, but most are designed for mainstream populations and overlook the needs of culturally diverse communities. To address this gap, we co-designed and developed DESI-Heart, a culturally tailored CA promoting self-care among Indian Australians with CVDs. This study evaluates the feasibility and usability of the 8-week DESI-Heart intervention.

Methods: Informed by the initial co-design phase, the 8-week DESI-Heart program comprised four culturally and linguistically tailored modules: (1) medication reminders, (2) daily exercise guidance, (3) diet buddy, and (4) guided meditation. The study followed a single-arm pre-post pilot trial design (n=28) to assess the feasibility and usability of the DESI-Heart program. After completing the pretest assessments, participants accessed DESI-Heart through a web-based CA, available on smartphones or laptops. According to their preferred schedules, participants received links to the relevant modules, delivered at four time points each week over an 8-week period. Upon completion of the program, participants were invited to complete a follow-up session, which included post-test assessments and qualitative feedback on their experience using DESI-Heart.

Results: These are the preliminary findings from our data analysis reported based on existing participants who completed our study (n=18). Primary outcomes of study assessed the feasibility and usability of the DESI-Heart program. Feasibility was measured using recruitment rates, participant retention, completion of the prescribed self-care program and attrition. Recruitment rate was 100% (18/18), participant retention was 88.88% (16/18) and completion of the set goals was 80.27% (2312/2880 sessions). Usability, assessed using the Chatbot Usability Scale, yielded a mean score of 80.5 (15/18).

Conclusion: Based on the preliminary analysis, the co-designed DESI-Heart program demonstrated strong feasibility, as indicated by satisfactory recruitment rates, high participant retention, completion of the prescribed self-care activities, and low attrition and usability. Insights from this phase will guide refinement of the intervention and inform the design of a larger-scale evaluation trial.

II-P-D.02

Predicting Physical Activity Recovery after Stressors Using Step Count Data Derived from Activity Monitors

D. Baretta¹, S. Koch², J. Buekers^{3,4}, J. Garcia-Aymerich^{3,5}, L. Knapova⁶, S. Elavsky⁶, J. Godino^{7,8}, M. Olthof⁹, A. Lichtwarck-Aschoff⁹, R. den Hartigh⁹, G. Chevance^{10,3}

¹University of Bern, Institute of Psychology, Bern, Switzerland, ²University of Basel, Basel, Switzerland, ³ISGlobal, Barcelona, Spain, ⁴CIBER Epidemiología y Salud Pública (CIBERESP), Barcelona, Spain, ⁵Universitat Pompeu Fabra (UPF), Barcelona, Spain, ⁶University of Ostrava, Ostrava, Czech Republic, ⁷Family Health Centers of San Diego, San Diego, United States, ⁸UC San Diego, San Diego, United States, ⁹University of Groningen, Faculty of Behavioural and Social Sciences, Groningen, Netherlands, ¹⁰University Rennes, Inserm, EHESP, Irset (Institut de Recherche en Santé, Environnement et Travail), Rennes, France

Purpose: Physical activity is essential for health and well-being but is vulnerable to disruptions from various stressors (e.g., individual and environmental factors). Responses to such disruptions vary both across individuals and within individuals over time. Advances in mobile sensing enable the precise analysis of stressor-response trajectories using high-resolution time series data. Tracking daily changes in step counts allows researchers to model and predict the dynamics of individual responses, including the direction and pace of the stressor-response trajectory. Complex systems theory, particularly early warning signals, provides a framework for predicting individual progression through behavioral stressor responses. In this study, we investigated whether local dynamic complexity (DC) in step count—a statistical marker of early warning signals—could predict the future rate of change in the stressor-response trajectory.

Methods: We analyzed step count time series from 226 participants in the California, Czech Republic, Spain, and Norway following the first COVID-19 lockdown (the stressor). Daily step counts were measured using activity monitors (Fitbit, Garmin). The daily rate of change in the stressor-response trajectory (DV) was calculated as the first-order derivative of a growth function fitted to the time series. Local DC (IV) was assessed by analyzing fluctuations in step counts using a 14-day rolling window. Multilevel modeling was used for analysis.

Results: Local DC significantly predicted decreases in the rate of change 11 days later ($B = -35.62$, 95% CI $[-45.32, -25.92]$). This effect suggests that 15 days with local DC levels exceeding 1 standard deviation could result in a „delay“ of more than 500 steps per day in the average stressor-response trajectory.

Conclusion: This study demonstrates how step count data from activity monitors can be used to characterize and predict stressor-response trajectories in physical activity. These findings highlight opportunities for just-in-time interventions to support the recovery of physical activity after disruptive stressors.

II-P-D.03

Opportunities and Challenges to Supporting Motivation and Health Behaviour Change in UK Uniformed Services through Digital Interventions

M. Warmer^{1,2}, M. Western^{1,2}, J. Bilzon¹, J. Fallowfield³

¹University of Bath, Department for Health, Bath, United Kingdom, ²Centre for Motivation and Behaviour Change, Health, Bath, United Kingdom, ³Royal Navy People Support (Musculoskeletal Injury Mitigation and Nutrition), Portsmouth, United Kingdom

Purpose: Musculoskeletal injuries (MSKI) are a leading cause of medical discharge, training delays, and healthcare burden within the Royal Navy (RN). Modifiable health behaviours (physical fitness, diet quality, sleep, alcohol consumption and nicotine use) increase MSKI risk. Developing supportive workplace environments and targeted digital health (e-health) interventions show promise for supporting positive health-related behaviour change. However, the efficacy of e-health technologies rely on design features to: sustain engagement; facilitate reach to a high volume of users; and align with end-users' lived experiences. This qualitative study investigated barriers and facilitators to health behaviour change in early-stage RN personnel to inform the design of an e-health intervention to promote musculoskeletal health.

Methods: Following the Person-Based Approach framework, co-design workshops (n=56) were conducted with early-career stage participants. Data were synthesised using thematic framework analysis to code statements related to barriers and facilitators for health behaviour change and intervention design features, which were mapped onto the COM-B model.

Results: Facilitators for engaging in positive health-related behaviours included understanding the benefits of physical

D. E- & mHEALTH

activity, how to be physically active and being aware of MSKI risk factors. Barriers encompassed environmental and structural factors such as limited access to health and fitness education, time constraints, equipment, low baseline fitness, and a lack of accountability for health at both individual and organisational levels. Participants emphasised the value of a hybrid approach to health behaviour change intervention delivery, combining environmental improvements (e.g., improving food provision, creating opportunities to self-cater and engage in physical activity, and improved access to health practitioners) with the use of digital technology. Key features identified for an e-health solution included access to evidence-based, population-specific health and fitness information, personalised health recommendations, opportunities for peer encouragement, and integration with wearable fitness trackers to enable goal setting, self-monitoring, and foster intrinsic motivation.

Conclusion: This study supports that effective workplace digital interventions must address both environmental and motivational determinants of behaviour, and not just take the form of an individual application. Sustained behaviour change in constrained workplaces requires whole system engagement, combined with interventions that support psychological needs and drive intrinsic motivation.

II-P-D.04

Participants' Experiences of Using the SPARK App to Support Gestational Diabetes Management: Qualitative Findings from the SPARK Trial

E. Söderström Shields¹, M. Ersson¹, K. Åsberg^{2,1}, J. Sandborg^{2,1}, M. Löf¹

¹Karolinska Institutet, Department of Medicine, Huddinge, Stockholm, Sweden, ²Region Östergötland, Linköping, Sweden

Purpose: Gestational diabetes (GDM) affects approximately 17% of pregnancies globally. Effective GDM management is key in preventing adverse maternal and child outcomes, highlighting the need for effective interventions to support glucose control. The randomized controlled trial, SPARK, evaluates a novel smartphone app that supports women in managing their glucose levels through a lifestyle behavior change program (n=334 enrolled November 2025). This qualitative study explores women's experiences of navigating a GDM diagnosis and using the SPARK app as a digital support tool for GDM management.

Methods: Semi structured interviews were conducted in late pregnancy with participants that had used the SPARK app (n=20). The included women were representative of the whole intervention group in terms of age (32.8±4.0 vs. 32.1±6.7 years), proportion of women with overweight and obesity (74% vs. 77%), and proportion of foreign-born women (30% vs. 27%). Interviews were conducted through video calls and were transcribed verbatim. Data was analyzed using reflexive thematic analysis with an inductive approach.

Results: Preliminary findings suggest that navigating the diagnosis initially evoked feelings of guilt and uncertainty about how to manage GDM, followed by rapid lifestyle adjustments. The SPARK app was perceived as a trustworthy, comprehensive and reliable companion that provided support and guidance for managing GDM and making behavior changes. The app supported women in understanding their glucose levels, and made them reflect on how lifestyle modifications influence glucose levels, and establish new routines. Over time, the app contributed with a sense of control, confidence and self-efficacy in managing GDM.

Conclusion: Findings from this study indicate that the SPARK app may play a valuable role in the self-management of GDM by supporting dietary and physical activity changes. The app has the potential to complement standard care for GDM patients. Future research should investigate healthcare professionals' perspectives on integrating the app into routine clinical practice.

II-P-D.05

Healthcare Professionals' Experiences of Supporting Health Behaviors in Migrant Women after Childbirth: Opportunities for mHealth Integration

M. Shirvanifar¹, U. Müssener¹, A. Lindh¹, J. Wangdahl^{2,3,4}, P. Henriksson¹

¹Linköping University, Health, Medicine and Caring Sciences (HMC), Linköping, Sweden, ²Karolinska Institutet and Stockholm University, Aging Research Center, Stockholm, Sweden, ³Karolinska Institutet, Division of Nursing, Department of Neurobiology, Care Sciences, and Society, Stockholm, Sweden, ⁴Uppsala University, Department of Public Health and Caring Sciences, Uppsala, Sweden

D. E- & mHEALTH

Purpose: The period after childbirth offers a critical opportunity to promote women's long-term health. Migrant women face unique barriers to healthy lifestyles, yet little is known about how healthcare professionals support them after childbirth. To the best of our knowledge, no previous study in Sweden—or in other high-income countries with similar migration patterns—has explored these professionals' perspectives. This study examined healthcare professionals' experiences of promoting health behaviors in migrant women after childbirth and their views on the potential of mobile health (mHealth) tools in this context.

Methods: This qualitative interview study, part of the PRIMI (Promoting Reproductive health In Migrant women) project, included 20 female healthcare professionals (e.g. midwives, dietitians, physicians, health communicators) from four Swedish regions. Semi-structured interviews were analyzed using reflexive thematic analysis following Braun and Clarke, guided by the Reflexive Thematic Analysis Reporting Guidelines (RTARG). Dependability, credibility, and transparency were ensured through independent coding by two researchers, collaborative analysis meetings, and adherence to RTARG.

Results: Three main themes were identified:

1. Priorities and routines of health behavior promotion after childbirth – health promotion for mothers, especially migrants, was often deprioritized with unclear responsibilities and limited time.
2. Social influences on health behaviors – language barriers, limited knowledge, economic constraints, and a lack of social networks hindered healthy habits, while peer support could motivate change.
3. mHealth in supporting health behaviors after childbirth – culturally adapted, multilingual apps with reliable information, visuals and audio features were viewed as promising tools to increase accessibility and engagement.

Conclusion: Healthcare professionals described a lack of structured routines and resources for promoting healthy behaviors in migrant women after childbirth. Culturally competent healthcare professionals combined with tailored mHealth tools could help bridge these gaps. These findings extend behavior-change theory to a multicultural maternal-health context and inform the co-design of equitable, culturally sensitive digital interventions to promote long-term wellbeing.

II-P-D.07

Lessons Learned from Working with Community Members: Gaining Community Buy-in for Developing Artificial Intelligence-enhanced Physical Activity Interventions

G.E. Brannon¹, A. On², S. Wang³, S. Makhnoon⁴, J. Szeszulski⁵, Y. Liao²

¹University of Texas at Arlington, Communication, Arlington, United States, ²University of Texas at Arlington, Kinesiology, Arlington, United States, ³University of Texas at Arlington, Industrial and Manufacturing Systems Engineering, Arlington, United States, ⁴UT Southwestern, Public Health, Dallas, United States, ⁵Texas A&M AgriLife, Nutrition, Dallas, United States

Purpose: Involving community members is essential for developing effective patient-centered behavioral and physical activity (PA) interventions, particularly when integrating new technologies. However, building the relationships needed for meaningful engagement takes time and can be challenging. The objective of this study was to assess lessons learned from working with community partners to develop an artificial intelligence (AI)-enhanced PA intervention.

Methods: We engaged with the 20-member community advisory panel (CAP) of a university-based tertiary healthcare system in Texas at two separate hospital campus CAP meetings (October 2024, March 2025). The racially/ethnically diverse CAP members included 40% Black, 30% White, 20% Hispanic, and 10% Middle Eastern individuals. Members were predominantly women (80%) and mostly middle-aged (33%) or older adults (50%). The first meeting included 9 in-person and 5 virtual attendees; the second included 13 in-person and 3 virtual attendees. The first meeting focused on general AI perceptions, current experiences with AI tools, and opinions/concerns regarding AI's application in interventions. The second meeting involved a presentation of design mockups and potential features of an AI-enhanced PA intervention. One research team member facilitated the meeting; another served as notetaker and recorded observations.

Results: Relying on community locations provided logistical challenges with parking and building access as meetings were scheduled after working hours. The feedback and discussion from CAP members were positive towards the use of AI and machine learning in PA interventions. While opinions on AI's usefulness and trustworthiness were mixed, all CAP members acknowledged AI's growing integration into daily life and expressed a strong interest in learning

D. E- & mHEALTH

how to best utilize AI to improve health outcomes. CAP members appreciated the personalization and relevance of AI-generated messages using tailored health and location information and embraced the idea of integrating an AI chatbot as a support system. The positive input supports the research team to proceed with incorporating AI and machine learning in intervention design while being mindful about transparency and credibility of resources provided through AI.

Conclusion: AI-enhanced PA interventions show promise and support, especially for personalization and relevance in messaging. Future interventions should ensure transparency in AI usage and consider the usefulness, trustworthiness, and credibility of AI-provided resources.

II-P-D.08

Adolescent Athletes' Dietary Habits after Use of *PLAYTE*: A Proof-of-Concept Study

A.L. Deslippe^{1,2}, T.R. Cohen^{3,2}

¹University of British Columbia, Human Nutrition, Vancouver, Canada, ²British Columbia Children's Hospital Research Institute, Healthy Starts, Vancouver, Canada, ³University of British Columbia, Food, Nutrition and Health, Vancouver, Canada

Purpose: Emerging evidence suggests that adolescent athletes (13-18 years) have a high prevalence of unfavourable dietary habits including consumption of high caffeine energy drinks, reliance on sport supplements and food restriction. As there is no school policy and regulated nutrition resources in Canadian secondary schools this represents a missed opportunity to support these athletes. To address this gap, we co-created a novel sport fueling app called *PLAYTE* that relies on plate-based eating. Plate-based eating has potential to promote more intuitive eating behaviours and positive food-relationships by removing eating based on rigid numbers. The aim of this study is to evaluate trends in athletes' dietary behaviours after using *PLAYTE* (i.e., *PLAYTE*'s proof-of-concept).

Methods: Eighty athletes (40 males; 40 females) from schools (grades 8-12) around Vancouver are being recruited (Canada) who participate in at least one school sport. Prior to using *PLAYTE*, athletes report their demographics, sport and dietary history, and complete 3 electronic 24-hour dietary records. After using *PLAYTE* for 4 weeks dietary records are repeated. Once the full sample is collected (Dec 2025), within-person changes in energy balance from the pre- to post-intervention period will be assessed using paired t-tests. Trends in macronutrient intake (protein, carbohydrate, fat) will be analyzed using validated dietary assessment software, with proportions compared to 'ideal proportions' based on the validated Athlete's Plate™.

Results: Sixty-four athletes (25 males; 39 females) have been recruited and represent diverse grades (Grade 8: n=7; Grade 9: n=11; Grade 10: n=20; Grade 11: n=15; Grade 12: n=11). Most athletes are multi-sport and participate in basketball (n=22), volleyball (n=17), ultimate frisbee (n=15), cross country running (n=10), swimming (n=9), badminton (n=9), soccer (n=8), rugby (n=6), and track and field (n=6). Twenty-nine athletes identified as White, 16 as Chinese, 9 as Middle Eastern, and 9 as South Asian.

Conclusion: If trends in teen athletes' dietary behaviours are favourably following *PLAYTE* use (e.g., better alignment with recommendations), *PLAYTE* is ready for next-step efficacy testing. As there are no regulated nutrition resources for athletes in Canadian schools this research is a critical step in establishing if *PLAYTE* may have promise as a novel resource schools could implement.

II-P-D.09

Effect of Experience and Time on Usability in the Fitmobapp Application to Collect Fitness Data

J. Brazo-Sayavera¹, G. Angulo-Garay¹, F. Gómez-Vela¹

¹Universidad Pablo de Olavide, Sports and Computer Sciences, Seville, Spain

Purpose: This study aimed to evaluate changes in usability scores between two time points in the use of the application Fitmobapp, while accounting for key participant characteristics, including age, sex, educational level, professional sector experience, and experience in evaluating physical fitness.

Methods: System Usability Scale (SUS) scores were calculated from participants' responses to 10-item questionnaires administered at two occasions. Missing data were addressed using multiple imputation to reduce bias. The data were

D. E- & mHEALTH

reshaped into a long format to reflect repeated measures per participant. A linear mixed-effects model was fitted with time (R1 vs. R2) as the main predictor and covariates including age, sex, education, sector experience, and evaluation experience. Random intercepts were included to account for individual variability.

Results: The model revealed a non-significant trend toward increased SUS scores at the second evaluation compared to the first (+2.5 points, $p = 0.0635$). Among covariates, only experience evaluating physical fitness was significantly associated with higher usability scores (+1.04 points per unit increase, $p = 0.018$). Other factors such as age, sex, education, and sector experience showed no significant effects.

Conclusion: While SUS scores tended to improve over time, this change was not statistically conclusive. Experience evaluating physical fitness emerged as an important factor influencing perceived usability, suggesting expertise impacts usability ratings. Considering participant characteristics via covariates resulted in a more accurate and nuanced understanding of usability changes within the same individuals over time.

II-P-D.10

Development of a Quality Assessment Tool for Validation Studies of 24-hour Physical Behavior via Wearables: A Delphi Study

I. Timm¹, M. Giurgiu¹, D. Wohlfarth², S. Abdullah³, M. Adamakis⁴, J.K. Baumgart⁵, K. Denecke⁶, C. Doherty⁷, J. Dygryn⁸, J. Fiedler¹, C. Gawrilow⁹, S. Keadle¹⁰, R. Lambe¹¹, A. LeFaucheur¹², C. Lendt¹³, Y. Liao¹⁴, A. Lu¹⁵, A.I. Martinko^{16,17}, M. Charles¹⁸, A. Pesalo¹⁹, M. Schmidt²⁰, B. Semiz²¹, M. Soric^{16,17}, T. Vetrovsky²², K. Wunsch^{1,23}, M. O'Brien²⁴, P. Saint-Maurice²⁵, A. Tornberg²⁶

¹Karlsruhe Institute of Technology, Institute of Sports and Sports Science, Karlsruhe, Germany, ²University Hospital Ulm, Sports and Rehabilitation Medicine, Ulm, Germany, ³Mälardalen University Västerås, Division of Intelligent Future Technologies, School of Innovation, Design and Engineering, Västerås, Sweden, ⁴National and Kapodistrian University of Athens, School of Physical Education and Sport Science, Athens, Greece, ⁵Norwegian University of Science and Technology, Faculty of Medicine and Health Science, Trondheim, Norway, ⁶Bern University of Applied Sciences, Institute Patient-centered Digital Health, Bern, Switzerland, ⁷University College Dublin, Insight Centre for Data Analytics, Dublin, Ireland, ⁸Palacký University Olomouc, Faculty of Physical Culture, Olomouc, Czech Republic, ⁹University of Tuebingen, Department of Psychology, Tuebingen, Germany, ¹⁰California Polytechnic State University, Department of Kinesiology and Public Health, San Luis Obispo, Canada, ¹¹University College Dublin, School of Public Health, Physiotherapy and Sports Science, Dublin, Ireland, ¹²Univ Rennes, M2S (Laboratoire Mouvement, Sport, Santé), Rennes, France, ¹³University of Regensburg, Department of Epidemiology and Preventive Medicine, Regensburg, Germany, ¹⁴The University of Texas at Arlington, Department of Kinesiology, Arlington, United States, ¹⁵Northeastern University Boston, Health Technology Lab, Department of Communication Studies, College of Arts, Media, and Design, Department of Public Health and Health Sciences, Bouvé College of Health Sciences, Boston, United States, ¹⁶University of Zagreb, Faculty of Kinesiology, Zagreb, Croatia, ¹⁷University of Ljubljana, Faculty of Sport, Ljubljana, Slovenia, ¹⁸National Cancer Institute Rockville, Metabolic Epidemiology Branch, Division of Cancer Epidemiology and Genetics, Rockville, United States, ¹⁹South-Eastern Finland University of Applied Sciences Mikkeli, Preventive Health Research Unit, Active Life Laboratory, Mikkeli, Finland, ²⁰TU Dortmund University, Institute for Sport and Sport Science, Dortmund, Germany, ²¹Koç University Istanbul, Department of Electrical and Electronics Engineering, Istanbul, Turkey, ²²Charles University Prague, Faculty of Physical Education and Sport, Prague, Czech Republic, ²³Fresenius University of Applied Sciences, Heidelberg, Germany, ²⁴Université de Sherbrooke, Faculty of Medicine and Health Science, Sherbrooke, Canada, ²⁵Champalimaud Foundation Lisbon, Breast Cancer Research Program, Lisbon, Portugal, ²⁶Lund University, Department of Health Sciences, Lund, Sweden

Purpose: Wearables are increasingly considered a valid and scalable approach for measuring 24-hour physical behavior, including physical activity, sedentary time, and sleep. Despite their widespread use in research and clinical practice, there is currently no standardized framework for evaluating the methodological quality of validation studies on these devices. This project aims to develop a consensus-based Quality Assessment (QA) Tool for validation studies of wearables through a multi-round Delphi process. The study is part of the broader Wearable Landscape initiative, which also develops a complementary reporting checklist for validation studies.

Methods: A multi-round Delphi process is being conducted between September 2025 and February 2026 using SoSci Survey. International experts in wearable validation ($n = 644$), identified through systematic literature reviews and AI-assisted search, were invited to rate and refine potential QA criteria. In Round 1, participants assess the relevance and clarity of candidate items on a 9-point Likert scale. In subsequent rounds, participants receive both personal and anonymized group feedback (median, interquartile range, qualitative comments) and can adjust their ratings to foster consensus. The consensus threshold for item inclusion is defined as $\geq 70\%$ of ratings within the 7-9 range. Quantitative data will be analyzed using descriptive statistics and consensus metrics; qualitative feedback will be

D. E- & mHEALTH

thematically summarized to inform item revision.

Results: Round 1 is currently ongoing with $n = 40$ respondents, and data collection is scheduled to conclude in November 2025. Preliminary analyses will identify items achieving strong consensus as well as domains requiring refinement. The expected outcome is a structured, transparent QA Tool encompassing key domains such as patient selection, study design, reference measure, data synchronization, and statistical analyses.

Conclusion: This consensus-based QA Tool will enhance transparency, comparability, and methodological rigor in wearable validation research. The results will support researchers, reviewers, and policymakers in evaluating the study quality and will contribute to the harmonization of reporting standards in 24-hour physical behavior measurement.

II-P-D.11

Impact of Accelerometer Epoch Summary Measure on Associations between Physical Activity and All-cause Mortality in Whitehall II and UK Biobank

H.R. Eckmann¹, C. Razieh¹, I. Meneghel Danilevicz², S. Vidil², S. Chastin³, L.B. Sherar⁴, B.H. Hansen⁵, P.C. Dempsey⁶, S. Sabia², A.V. Rowlands¹

¹University of Leicester, Diabetes Research Centre, Leicester, United Kingdom, ²Inserm, Epidemiology of Ageing and Neurodegenerative Diseases, Paris, France, ³Glasgow Caledonian University, School of Health and Life Sciences, Glasgow, United Kingdom, ⁴Loughborough University, School of Sport, Health and Exercise Sciences, Loughborough, United Kingdom, ⁵University of Agder, Department of Sport Science and Physical Education, Kristiansand, Norway, ⁶Institute for Physical Activity and Nutrition, Deakin University, School of Exercise and Nutrition Sciences, Burwood, Australia

Purpose: Raw accelerometer data are commonly reduced into epoch summary measures for analysis, e.g. ENMO (Euclidean Norm Minus One), MAD (Mean Amplitude Deviation), MIMS (Monitor Independent Movement Summary) or Counts. No consensus exists around choice epoch summary measure, as ENMO, MAD, MIMS, and Counts have all been employed in recent large-scale studies. This study aimed to compare associations with all-cause mortality of the volume and intensity of physical activity when derived from four different measures (ENMO, MAD, MIMS and Counts) in two large cohorts – Whitehall II and UK Biobank – where combined associations with mortality of PA volume and intensity generated from the ENMO measure have previously been demonstrated.

Methods: Accelerometer-assessed volume (Average Acceleration, AvAcc) and intensity distribution (Intensity Gradient, IG) were derived from ENMO, MAD, MIMS and Counts. Higher values of IG indicate a larger proportion of PA accumulated at higher intensities. Associations with mortality were estimated using Cox Proportional Hazards models.

Results: 3,733 (25.1% female, median (IQR) age 68.3 (64.7, 73.8) years) and 89,848 (56.4% female, 63.5 (56.3, 68.6) years) participants were included from Whitehall II and UK Biobank, respectively. Median (IQR) follow-up was 11.0 (10.7, 11.3) and 8.0 (7.5, 8.5) years, with 563 (15.1%) and 3,656 (4.1%) deaths, respectively. Patterns of associations with mortality were largely consistent between measures. Irrespective of measure, the lowest mortality risk was for those high (above the median) in both AvAcc and IG (Range of hazard ratios in Whitehall: 0.59-0.68; in Biobank: 0.55-0.61, reference: low AvAcc / low IG). IG was associated with lower mortality risk, irrespective of AvAcc, measure or cohort. AvAcc was associated with lower mortality irrespective of IG or measure in Biobank only.

Conclusion: Associations of Average Acceleration and Intensity Gradient with mortality are broadly consistent across common epoch summary measures, with some inconsistencies in numerical estimates and relative impacts of volume versus intensity of physical activity. These findings support a fair, but not strict, comparability of activity-health findings across studies using different epoch summary measures.

II-P-D.12

Beyond Cut-points: Using Advanced Statistical Approaches to Refine the Understanding of the Associations between Accelerometer-measured Physical Activity and Body Mass Index

J. Lopez Garcia¹, I.M. Danilevicz¹, N. Berger², B.H. Hansen³, J. Steene-Johannessen⁴, E. Aadland⁵, S. Sabia^{1,6}

¹Université Paris Cité and Université Sorbonne Paris Nord, Inserm U 1153, INRAE, Centre for Research in Epidemiology and Statistics (CRESS), Epidemiology of Ageing and Neurodegenerative Diseases (EpiAgeing), Paris, France, ²Sciensano (Belgian Scientific Institute of Public Health), Department of Epidemiology and Public Health, Brussels, Belgium, ³University of Agder, Department of Sport Science and Physical Education, Kristiansand, Norway, ⁴University of Agder,

D. E- & mHEALTH

Department of Sports Medicine, Kristiansand, Norway, ⁵Western Norway University of Applied Sciences, Department of Sport, Food and Natural Sciences, Sogndal, Norway, ⁶University College London, Faculty of Brain Sciences, London, United Kingdom

Purpose: Traditionally, cut-point methods have been used to classify accelerometer data into broad intensity categories, but the lack of standardization across calibration studies has limited the comparability and interpretation of the findings. The activity intensity distribution has emerged as an alternative approach to fully exploit the rich and high-resolution accelerometer data while going beyond the lack of consensus on cut-points. Commonly-used analytical approaches, such as linear regression, are not suited to handle the complex nature of the entire intensity distribution; therefore, advanced statistical analysis across the lifespan are needed. This study aims to evaluate whether analysing the activity intensity distribution, rather than cut-point-derived intensities, provides insightful information on the associations between movement behaviours and body mass index (BMI) across the lifespan.

Methods: Accelerometer data from four cross-sectional studies in Norway and Belgium were analysed (n=7112, 3–90 years, 53% female). Associations between movement behaviours and BMI were investigated using linear regressions for the cut-point approach, and functional data analysis (FDA) as well as multivariate pattern analysis for the activity intensity distribution, in six different age groups (preschoolers, children, adolescents, younger adults, middle adults and older adults).

Results: Time in physical activity (PA) and sedentary behaviour (SB) varied substantially by the cut-point applied (e.g., in children: $SB_{Evenson} 438.8 \pm 57.5$ vs $SB_{Romanzini} 477.4 \pm 57.3$ vs $SB_{Puyau} 597.2 \pm 55.8$ min/day, $P < 0.001$). SB was associated to a higher BMI in children and adults, while moderate to vigorous intensity was associated with a lower BMI. However, the magnitude of associations varied considerably depending on the cut-points used. FDA and multivariate pattern analyses showed that these associations within the SB range, were mainly driven by the time in zero counts, and that the minimum PA intensity associated with a lower BMI decreased with age (e.g., 989 vs 450 counts/15s in young and older adults, respectively).

Conclusion: FDA and multivariate pattern analysis provide a detailed picture of PA and BMI associations across the lifespan, overcoming the limitations of cut-points. These approaches enhance comparability between studies and reveal specific associations that may be masked by traditional cut-points, supporting their use in future accelerometer-based research.

II-P-D.13

Integrating Wearables and Ecological Momentary Assessment for Multimodal Monitoring of Children's Movement and Digital Behaviours: The ReDiKid Study

T. Vetrovsky¹, V. Dostalova¹, P. Popelkova¹, J. Kuhnova¹, A. Faltysova¹, R. Cimler¹, M. Giurgiu², M. Saradin Lebedikova³, M. Tkaczyk³, D. Smahel³, J. Vindis⁴, A. Gaba⁴, J. Dygryn⁴, J. Pelclova⁴

¹University of Hradec Kralove, Center of Advanced Technologies, Faculty of Science, Hradec Kralove, Czech Republic,

²Karlsruhe Institute of Technology, Mental mHealth Lab, Institute of Sports and Sport Sciences, Karlsruhe, Germany,

³Masaryk University, Interdisciplinary Research Team on Internet and Society, Faculty of Social Studies, Brno, Czech Republic, ⁴Palacky University Olomouc, Faculty of Physical Culture, Olomouc, Czech Republic

Purpose: Children's movement behaviours and digital media use interact throughout the day and shape their stress regulation, recovery, and resilience. However, these behaviours are usually assessed separately or with limited temporal resolution. Wearable devices offer opportunities to monitor experiences continuously, but proprietary processing restricts transparency and comparability. The *ReDiKid* study leverages raw accelerometer and beat-to-beat interval data from a Garmin watch and integrates these signals with smartphone analytics and ecological momentary assessment (EMA). This multimodal approach enables high-resolution examination of how movement behaviours, digital engagement, and stress relate in everyday life.

Methods: Two hundred children aged 9–11 years will participate in a two-week ambulatory monitoring. Movement behaviours and heart rate variability will be continuously recorded using a *Garmin vivoactive* watch. A custom-built app, *Garçon* (developed using Garmin's SDK), captures raw accelerometer (25 Hz) and beat-to-beat interval data while simultaneously streaming processed metrics such as stress level and step count. In parallel, the *eBehave* app monitors smartphone patterns (e.g., screen time, app use). Both data streams are processed via the *HealthReact* platform, which delivers gamified EMA surveys capturing experiences, stress, sleep, and context. Surveys are initiated through a hybrid sampling strategy combining time-based prompts with event-based triggers activated by changes in stress level or behavioural and digital-activity patterns.

Results: The study will demonstrate the feasibility of integrating multimodal, real-time data streams from wearables, smartphones, and EMA into a unified framework for child behavioural research. The dataset will provide

D. E- & mHEALTH

high-resolution insight into short-term, bidirectional relationships between movement behaviours, digital media use, sleep, and stress. By linking continuous physiological and behavioural signals with in-the-moment self-reports, the study will offer a resource for identifying context-sensitive markers of resilience and opportunities for just-in-time adaptive interventions.

Conclusion: The *ReDiKid* study establishes a novel methodological infrastructure that combines continuous wearable sensing, smartphone analytics, and EMA. This multimodal approach enables observation of how children's movement behaviours, digital media use, and momentary experiences interact in daily life, providing a foundation for future resilience-promoting interventions.

II-P-D.14

Conversational Nutrition: The Enhancement of Dietary Assessment with an AI-driven Chatbot

L. Peters^{1,2}, G. Spada³, S. Schneider³, A. Middelweerd¹, S. Wopereis^{2,1}

¹University of Twente, EEMCS / BSS, Enschede, Netherlands, ²TNO, Health and Work, Leiden, Netherlands, ³University of Twente, HMI, Enschede, Netherlands

Purpose: Accurate dietary assessment is essential for personalized nutrition. However, traditional methods such as questionnaires are often burdensome and fail to sustain user engagement, resulting in unreliable data. Digital tools, including large language model-based systems, offer new opportunities to improve both assessment quality and user experience. The Nutri+ questionnaire is a validated, web-based tool for estimating habitual intake, but faces usability and engagement challenges. To address these, we developed an AI-driven chatbot that assesses habitual dietary intake through natural conversation. This study evaluated the chatbot-based dietary assessment and compared its usability, user-experience, and engagement with the questionnaire.

Methods: A mixed-methods, co-creation design consisting of three phases was employed among healthy adults. In phase one, user evaluation (n=6) of the Nutri+ questionnaire was conducted using the User Experience Questionnaire (UEQ; range -3 to +3) and User Engagement Scale-Short Form (UES-SF; range 1-5) to identify areas for improvement and guide chatbot design. In phase two (n=24), engagement techniques - nudging and gamification - were tested against a generic version of the chatbot using the UES-SF. In the final user-testing phase (n=35), a user-driven and system-driven chatbot are being evaluated using the UES and Chatbot Usability Questionnaire (range 1-5). Participants also provided qualitative feedback through open-ended questions, and quantitative metrics, like total session duration, were recorded.

Results: In phase one, the Nutri+ questionnaire scored highest on dependability (1.50/3.00), indicating a sense of control over the interaction, but lowest on novelty (-0.25/-3.00), suggesting limited innovation. Users reported confusion about portion sizes, frustration with the reporting interface, and fatigue. Overall engagement received an average score of 3.83/5.00. In phase two, both nudging and gamification yielded similarly high engagement (4.04/5.00 and 3.99/5.00, respectively), outperforming the mixed version (3.41/5.00). Consequently, both techniques were incorporated into two chatbot versions. Data collection from the final phase will be finalised in November 2025.

Conclusion: This chatbot represents a first step toward an innovative approach to dietary assessment. Incorporating nudging and gamification techniques can enhance engagement and retention, and potentially improve long-term adherence and data quality. These results indicate that Chatbot-based dietary assessment is a promising alternative to traditional self-report methods.

II-P-D.15

Effectiveness of the Click2Move Multi-component Intervention at Reducing Sedentary Behaviours in the Home-office

A. Coffey¹, I. Parés-Salomón², J. Bort-Roig², K. Proper³, A. Puig-Ribera², B. Loef⁴, A. M. Señé-Mir², M. Pajek⁵, I. Luznik⁵, R. Healy¹, C. Vaqué-Crusellas², K. Dowd¹

¹Technological University of the Shannon, Sport and Health Science, Athlone, Ireland, ²University of Vic, Sports and Physical Activity Research Group, Vic, Spain, ³Universiteit Amsterdam, Department of Public and Occupational Health, Amsterdam, Netherlands, ⁴National Institute for Public Health and The Environment, Centre for Prevention, Lifestyle and Health, Amsterdam, Netherlands, ⁵University of Ljubljana, Faculty of Sport, Ljubljana, Slovenia

D. E- & mHEALTH

Purpose: Office workers spend up to 66% of their day sitting. There has been a drastic increase in home-office working, which has been shown to further increase sitting time compared to the office environment. Existing research has focused on examining the effectiveness of interventions to reduce sitting time in a traditional office setting. This study investigates the effectiveness of the 12-month multi-component Click2Move intervention at reducing sitting time in home-office employees.

Methods: The evidence and theoretically informed Click2Move intervention included a wrist-worn device, phone application, educational material and organizational support and was delivered for 12 months. The primary outcome was occupational sedentary time, with physical activity behaviors as secondary outcomes and were measured using the activPAL^{3TM} at baseline, three, six and 12 months. Differences between groups in the change from baseline, at 3-, 6-, and 12-months for all outcome variables were estimated by fitting a linear mixed-effects model. Time, group, and their interaction were included as fixed effects, age, gender, and country included as covariates, and participant and company as random effects. Changes were examined across home office and traditional office settings, and during work hours and non-work hours.

Results: A total of 156 (46 male, 114 female) participants were recruited at baseline, with 134, 110 and 78 participants included at 3, 6 and 12-month time points respectively. The participants had a mean age of 39.8 years (SD=11.5) and an average of 2.8 days (SD=1.2) days working from home. Preliminary analysis showed significant differences between intervention and control groups in time in sedentary bouts of 30-60 minutes in duration between baseline and three months (Intervention = +11 minutes vs. Control = -7 minutes). No additional significant differences for any of the physical activity behaviors across all measured days were identified. Further analysis investigating physical activity and sedentary behaviors on home-office days, traditional office days, workdays and non-workdays will be finalized and reported at the conference.

Conclusion: A long-term multi-component digital intervention impacted sedentary bout accumulation in the intervention group with further analysis on home-office and office days pending.

II-P-D.16

Developing a Multidimensional Taxonomy for Physical Behavior Metrics: A Scoping Review

Z. Liu^{1,2}, B. Berendsen², R. Ma², H. Savelberg², K. Driessens¹

¹Maastricht University, Department of Advanced Computing Sciences, Maastricht, Netherlands, ²Maastricht University, Department of Nutrition and Movement Sciences, Maastricht, Netherlands

Purpose: Progress in monitoring techniques have led to more advanced metrics that provide richer information about how, when, and under what circumstances physical behaviors occur. The major challenges in physical behavior research are the lack of structure to organize and interpret these metrics, and the inconsistencies in terminology and computations. Such issues hinder comparability across studies and conclusions about physical behavior patterns and health. Hence, this review aims to develop a standardized taxonomy for transparently reporting metrics.

Methods: Studies applying accelerometer-derived physical behavior metrics were identified across PubMed and Embase databases. To include advanced metrics beyond summary volume-based measures, a two-stage screening was conducted. Besides the basic study characteristics, metrics and their characteristics such as data pre-processing, raw inputs, metric definitions and calculations were also extracted. Duplicate metrics were removed, and identical or similarly defined metrics were merged. A systematic method adapted from previous study was followed to develop the taxonomy consisting of definition-based dimensions for describing and assessing physical behaviors metrics, and those characteristics under each dimension. Conceptual-to-empirical and Empirical-to-conceptual iterations were proceeded until the characteristics under each dimension were mutually exclusive and exhaustive.

Results: A total of 734 metrics were extracted from the 308 included publications consolidated into 181 independent metrics for constructing taxonomy. The taxonomy comprises as follows: Temporal scope captures the time scale over which metrics are analyzed, ranging from short bouts to long-term cycles such as yearly patterns. Intensity representation refers to how physical intensity is expressed or derived, like cadence-based, energy-expenditure-based and postural classification. Computational complexity describes the number of processing steps required to compute a metric from raw signals. Applicability indicates whether metrics are designed for general use or tailored to specific populations or contexts, such as age- or condition-specific measures.

Conclusion: This taxonomy serves as a standardized tool that supports the structured and transparent description of physical behavior metrics with different dimensions. It provides a common framework for defining, computing, and comparing metrics across studies, and lays a conceptual foundation for future standardization and development of advanced behavior metrics.

II-P-D.17

Physical Behavior during School Days and Physical Education: Results from the MoMo 2.0-Study

J. Fiedler¹, M. Fleps¹, B. von Haaren-Mack², A.-C. Frenz¹, C. Niessner¹, A. Woll¹, C. Volk¹

¹Karlsruhe Institute of Technology, Institute of Sports and Sports Science, Karlsruhe, Germany, ²Federal Institute of Sport Science (BISp), Bonn, Germany

Purpose: As children and adolescents spend a large proportion of their time at school, schools represent an important setting to provide opportunities for an active school day. Previous studies have primarily focused on the intensity of physical activity during school days and in physical education by combining accelerometry with diary data. The present study aims at providing a holistic perspective on the physical behavior—such as sitting, stair walking, moving, walking, and running—for both total school days and physical education among children and adolescents from a nationwide sample in Germany.

Methods: Children and adolescents aged 4–17 years from the MoMo 2.0 Study wore ActivPal4 accelerometers on their right thigh for eight consecutive days and completed a daily diary noting times spent at school and during physical education. Raw accelerometer data were combined with the diary entries using the open-source ActiPASS software with age-adjusted cadence thresholds for walking to derive context-specific behavioral and intensity classifications. Only days where participants entered a school-specific time period were included in the analysis.

Results: A total of 1089 children and adolescents (male = 529 (48.6%) female = 560 (51.4%) age = 11.4 (3.1)) provided information about their school days on 4239 days with valid accelerometer data. Data processing has been completed, and the plausibility check will be finished by December 2025. The results of the analysis will present sex- and age-specific findings on time spent in different physical activity intensities, such as light and moderate-to-vigorous physical activity, as well as time spent in physical behaviors including sitting, standing, walking, running, and stair walking during a school day and during physical education.

Conclusion: The sensor-based recording and detailed analysis of the holistic perspective on physical behavior during a school day offer a wide range of new insights into the behaviors of children and adolescents. Additionally, challenges of data processing e.g. combining self-reported diary data with device-based measured data will be discussed. These results can help guide the school environment towards promoting a physically active and healthy lifestyle.

II-P-D.18

Device-measured Physical Activity and Sedentary Behaviour Patterns and their Associations with Cardiometabolic Health: A Systematic Review and Meta-analysis

T. Yona¹, J. Culverhouse², K. Driessens¹, H. Savelberg¹, B. Berendsen¹

¹Maastricht University, Maastricht, Netherlands, ²University of South Carolina, Columbia, United States

Purpose: Cardiometabolic diseases are a leading driver of mortality. We've long known that physical activity and sedentary behaviour are key modifiable lifestyle factors for prevention. But this knowledge may have a blind spot. While most of the literature assesses total volumes, the daily pattern, how we sequence, interrupt, and accumulate activity and sitting, may be an important factor for cardiometabolic health. However, previous research has primarily focused only on total volumes. This systematic review is the first to comprehensively synthesize evidence on patterns of device-measured physical activity behaviour, and their associations with cardiometabolic health outcomes in adults.

Methods: We conduct a systematic review following the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) statement. With an information specialist, we developed database-specific search strategies in four databases (MEDLINE, Embase, CINAHL, and Web of Science). Search strategies combined controlled vocabulary and free text across four domains – physical activity behaviors, patterns, devices, and cardiometabolic outcomes. Eligible studies are observational studies among adults (≥18 years) that use an objective device to measure at least one physical activity behaviour pattern metric, capturing its sequencing, timing, variability, and accumulation. Eligible outcomes include cardiometabolic biomarkers (e.g., glucose, lipids, blood pressure, adiposity), composite risk scores, and incident disease/mortality.

Data screening, extraction, and risk-of-bias assessment (using Joanna Briggs Institute tools) will be performed by pairs of reviewers. We will conduct a structured narrative synthesis and, where sufficient homogeneity exists, random-

D. E- & mHEALTH

effects meta-analyses and meta-regressions. The certainty of evidence will be assessed using the GRADE approach.

Results: A total of 23,854 records were identified (MEDLINE= 5,077; Embase= 8,734; Web of Science= 7,379; CINAHL= 2,664). De-duplication, screening, and data extraction are ongoing. The findings will be organized by pattern metrics and outcome domains. Our primary synthesis will focus on identifying which movement patterns demonstrate the strongest associations with different cardiometabolic health outcomes.

Conclusion: This review will provide the first synthesis of how daily movement patterns are consistently associated with cardiometabolic health. Our findings will inform metric selection, the development of pattern-specific public health guidelines, and the identification of pattern-related intervention targets.

II-P-D.19

Assessing the Temporal Relationship between Free-living Physical Activity and Affect in Adolescents: A Feasibility Study during the School Day

A.E. von Ah Morano^{1,1}, G. Brailey², L. Price³

¹University of Exeter, Public Health and Sports Science / Children's Health and Exercise Research Centre, Exeter, United Kingdom, ²University of Exeter, Faculty of Health and Life Sciences, Exeter, United Kingdom, ³University of Exeter, Faculty of Health and Life Sciences / Public Health and Sports Science, Exeter, United Kingdom

Purpose: Poor mental health among adolescents is a global concern due to its rising prevalence. Physical Activity (PA) has the potential to mitigate negative affect and enhance positive affect. However, the environment and the social context may influence this relationship and require further investigation. EMA and accelerometry can provide data on affect and PA, respectively. Although school time is often excluded from adolescent studies due to concerns that data collection could cause disturbance and may not be feasible, evidence is needed to determine if such methods can be implemented during school time. The purpose of this study is to explore the feasibility of using ecological momentary assessment (EMA) and wrist-worn accelerometry, including during school hours, to investigate the relationship between physical activity and affect in adolescents.

Methods: A total of 55 adolescents (55% female) from a state secondary school were enrolled in this study. EMA prompts were delivered to participants' mobile phones for 7 days, 5 times per day (Emmodie lab app) to assess affect and social context. During the same 7 day period, participants wore an accelerometer (GENEActiv set at 100 Hz) to record PA. The criteria adopted for valid assessments were: ≥ 15 EMA prompts answered, and ≥ 4 accelerometer wear days, including one weekend day with ≥ 16 hours/day.

Results: EMA adherence averaged 74%, with school-time prompts reaching 86% of total response. The criterion of at least 15 answered prompts was met by 89% of the sample. For PA, 92% of the participants had at least 4 valid days, and 75% completed all 7 days. Taken together, 76% of participants provided valid data for both PA and EMA.

Conclusion: EMA and accelerometry, including during school hours, is feasible to investigate affect and PA in adolescents. These methods should be used in a larger study to provide better guidance for tailoring PA interventions aimed at enhancing wellbeing during adolescence.

II-P-D.20

Online Dietary Reporting for Adults with Type 2 Diabetes: Developing a Protocol to Detect and Manage Potentially Fraudulent Responses

L. van Lunteren^{1,2}, R.M. Taylor^{1,3}, C.E. Collins^{1,3}, R.C. Asher^{1,3}

¹The University of Newcastle, School of Health Sciences, Callaghan, Australia, ²Wageningen University and Research, Wageningen, Netherlands, ³Hunter Medical Research Institute, Nutrition and Metabolic Research Program, New Lambton Heights, Australia

Purpose: Online research is an effective method to reduce research costs, access diverse or hard to reach populations, and support rapid data collection. However, online research increases exposure to bot generated and fraudulent/imposter responses, threatening data integrity and wasting research funds. Researchers conducting an online observational study assessing feasibility and acceptability of digital dietary reporting in adults with diabetes observed suspicious response patterns following social media recruitment. The objective of this research is to develop a protocol to differentiate genuine from fraudulent responses.

Methods: Participants were asked to complete six online Research Electronic Data Capture (REDCap) surveys, an

D. E- & mHEALTH

online food frequency questionnaire (FFQ) and two fourday (digital and traditional paper-based) food diaries. eGift cards reimbursed participants. Participants accessed the surveys via a public link. Initial recruitment was from a database of previous research participants, followed by social media posts. Estimated basal metabolic rate (BMR) was calculated using the Mifflin-St Jeor equation and compared to Goldberg cutoffs (physical activity level=1.55) to flag FFQ missreporting. Suspicious indicators included nonAustralian or invalid phone numbers, placeholder or mismatched postcodes, rapid survey completion time, inconsistent reporting, and implausible FFQ reported energy intakes. Three or more indicators flagged suspicious, potentially fraudulent responses.

Results: Of 161 respondents who consented, 80 completed the FFQ, 47 completed two food diaries. Of participants completing two food diaries, 39 completed records were flagged as suspicious (64% ≥ 3 suspicious indicators and 26% ≥ 5 indicators). No responses prior to social media recruitment were flagged suspicious. In responses following social media recruitment (n=43), median FFQ energy intake was 25280 kJ/day (71% under/overreporters), compared to 8270 kJ/day (25% under/over-reporters) pre-social media promotion (n=4). Twenty-six percent completed the FFQ in less than half the median time.

Conclusion: Careful planning of online recruitment, survey design, fraud detection and management in online research is essential for protecting data integrity, upholding ethical research practices, and reducing the burden of fraudulent responses on researchers. Strategies must also be balanced to minimise participant burden. The protocol to detect suspicious response can inform recruitment and fraud detection in future online/digital nutrition research.

II-P-D.21

A Novel Approach Aiming to Reduce Overestimation of Self-reported Physical Activity Levels: SKIP-Questionnaires

E.HGM Collombon¹, R.HJ Golsteijn¹, A.MMP Wijnands¹, C. Vullings¹, A. Oenema¹, L. Lechner¹

¹Open University of the Netherlands, Faculty of Behavioral and Health Sciences, Heerlen, Netherlands

Purpose: Accurate measurement of physical activity (PA) is essential for evaluating intervention effects, but remains challenging. Although self-report questionnaires are feasible in large scale studies, they are known to substantially overestimate PA compared to accelerometry. In this study, a novel approach using routing formulas in an online version of the Short Questionnaire to Assess Health-enhancing Physical Activity (SQUASH) is presented and tested. We hypothesize that incorporating automated routing algorithms will reduce misreporting and improve convergent validity with accelerometer data.

Methods: Baseline data were used from three trials: CARE-FIT (n=356) and OncoActive (n=430), including cancer patients, and Active4Life (n=722), including adults aged ≥ 50 years. In OncoActive, participants completed either a paper-based (n=141) or online (n=289) SQUASH. Active4Life participants completed the online SQUASH. CARE-FIT participants completed an adapted online version incorporating multiple routing formulas (SKIP-SQUASH). In all trials, PA was objectively assessed using ActiGraph accelerometers. Convergent validity, extreme-group validity, and mean differences between self-reported and accelerometer-based moderate-to-vigorous PA (MVPA) were calculated per dataset and compared across SQUASH versions. Independent t-tests were conducted to compare misreporting between questionnaire formats ($p < .05$).

Results: In OncoActive and Active4Life, self-reported PA substantially exceeded accelerometer-based PA. Mean overestimation of MVPA was 569 min/week (paper-based) and 574 min/week (online) in OncoActive, and 597 min/week in Active4Life. Based on these findings, the SKIP-SQUASH was developed and implemented in CARE-FIT. Baseline measurements of the CARE-FIT study are currently completed. Comparative analyses will determine whether the SKIP-SQUASH reduces absolute overestimation and improves correlations with accelerometer-based PA compared to traditional SQUASH formats.

Conclusion: This study addresses an important issue in PA research: systematic overreporting in self-report questionnaires. Incorporating routing formulas and accordingly restructuring questionnaire flow enables more efficient navigation through online self-report PA questionnaires. By skipping irrelevant questions, it is expected that this approach leads to improved validity and reduced overreporting of PA levels. If this approach is effective for the SQUASH questionnaire, the routing-approach could also be applied to other online PA questionnaires to enhance measurement accuracy.

D. E- & mHEALTH

II-P-D.22

Machine Learning Models for Predicting Free-living Activity Type from Raw Accelerometry and Heart Rate in Children

J.W. White III¹, R.G. Weaver¹, O.L. Finnegan¹, H. Yang², N. Niako³, B. Armstrong¹, S. Nelakuditi², K. Kiely¹, J. Culverhouse¹, Z. Zhong², B. Hadj-Amar³, M. Savidge¹, G.A.T. Randolph¹, K. Bowen¹, A.J. Holmes¹, M.W. Beets¹, E.L. Adams¹, S. Burkart¹, R. Ghosal³

¹University of South Carolina, Exercise Science, Columbia, United States, ²University of South Carolina, Computer Science and Engineering, Columbia, United States, ³University of South Carolina, Epidemiology and Biostatistics, Columbia, United States

Purpose: Predicting activity type (e.g., lying down, sitting, walking, running) is important for understanding what types of activities children engage in and for evaluating the effectiveness of built environment interventions to improve physical activity. While previous work has demonstrated high classification performance (>80%) for predicting children's activity types in semi-structured settings using accelerometry, more work is needed to evaluate classification performance across more granular activity types in free-living children. Including heart rate (HR) data may aid this pursuit. This study evaluates the performance of raw accelerometry and beat-by-beat HR data to predict granular activity types in free-living children compared to direct observation.

Methods: Children (n=85, mean age 8.5 ± 1.8 yrs, 38.8% female, 69.4% White) wore a research-grade accelerometer (ActiGraph GT9X) on their non-dominant wrist, and a chest-placed, research-grade HR monitor (Actiheart 5) while attending a day of summer camp. Children's activities were directly observed by trained research assistants using the SOSpan observation system. Activities were categorized into 13 activity types (e.g., Enrichment [arts and crafts, board games, watching a movie while sitting or standing], Kickball [any variation of a game of kickball], Circle Games [games played in a circle formation e.g., parachute games]). Random Forest (RF) and Support Vector Machine (SVM) classifiers were trained on 70 time-domain, frequency-domain, correlation, and angular features derived from raw accelerometry and HR by analyzing 60-second sliding windows to predict activity type at the second level. Leave-one-subject-out cross validation was used to evaluate model performance.

Results: A total of 486,139 observations were evaluated. RF and SVM exhibited low overall classification performance (weighted average F1 score: 51.7% and 50.4%, respectively). For RF, F1 scores ranged from 0% (Football, Kickball) to 83.1% (Enrichment, the majority class). For SVM, F1 scores ranged from 0.5% (Circle Games) to 81.7% (Enrichment).

Conclusion: Findings suggest RF and SVM models trained on features derived from raw accelerometry and beat-by-beat HR data were limited across more granular activity types in free-living children. More work is needed evaluating machine learning approaches and features that capture the distinct movement patterns associated with these activity types.

II-P-D.23

Psycho-social and Behavioral Associations of Perimenopause Symptom Burden: Study Protocol and First Results of a Needs Assessment for a Just-in-Time Adaptive Intervention

K. Haas¹, A. Schürch¹, W. Bierbauer², U. Scholz²

¹Bern University of Applied Sciences, Department of Health Professions, Bern, Switzerland, ²University of Zurich, Applied Social and Health Psychology, Zurich, Switzerland

Purpose: Perimenopause involves hormonal, physiological, and psychosocial changes that may negatively affect well-being and may increase the likelihood of unhealthy lifestyle behaviors, thereby elevating chronic disease risk. Despite its considerable public health relevance, this life phase remains underrepresented in behavior change research and interventions. This project aims to develop and evaluate a theory- and evidence-based Just-in-Time Adaptive Intervention (JITAI) for women in perimenopause, focusing on healthy dietary behavior and physical activity. The current research presents the study protocol and preliminary findings from the needs assessment phase.

Methods: The project follows a participatory, multi-phase development process guided by the Intervention Mapping framework, comprising three work packages.

WP1: Needs Assessment. A mixed-methods approach is used to identify psychological, behavioral, and social determinants of well-being and health behaviors during perimenopause. This includes (a) a quantitative cross-sectional survey (completed; reported here), (b) establishment of a participatory expert group of women from

D. E- & mHEALTH

the target population and stakeholders, and (c) an upcoming qualitative study exploring facilitators and barriers to healthy behaviors. Project (a) was co-developed with women to ensure relevance and acceptability. Purposive sampling aimed to approximate the educational distribution of women in Switzerland.

WP2: Intervention Development. Findings from WP1 will inform a logic model of change and the selection of theory- and evidence-based behavior change methods to design the tailored JITAs.

WP3: Implementation and Evaluation. The mobile-delivered JITAs will be evaluated in a micro-randomized trial assessing feasibility, engagement, and proximal behavioral outcomes.

Results: A total of 531 women aged 40–60 years participated in project (a) ($M_{age} = 48.9 \pm 6.3$; 62% low-to-medium education, 38% high education). Findings indicate substantial heterogeneity in symptom burden and behavioral adaptations. Overall, 41.8% reported weight gain during perimenopause. Approximately one quarter reported intentional changes in dietary behavior and/or physical activity in response to menopause.

Conclusion: This needs assessment provides an empirical and participatory foundation for the stepwise development of tailored JITAs to support healthy lifestyles and well-being during perimenopause. These findings represent the first phase of the project, informing subsequent qualitative research and the co-creation of diverse intervention components across the remaining work packages.

II-P-D.24

Timing Is Everything: Collecting Data to Develop Data-driven Digital Self-management Support for Hip and Knee Osteoarthritis

F. Groen¹, M. de Rooij^{1,2}, C.J.J. Klok³, C. Veenhof^{3,1}, M.C.A. Klein⁴, A. al-Janabi⁴, E.S. van Haeringen⁴, A. Ronteltap³, B. Paans-Cijs³, B. van Dongen⁵, D.E. Ginsel³, D.-J. Barten^{3,1}, T.J. Hoogeboom^{1,3}, M.F. Pisters^{1,6}

¹University Medical Center Utrecht, Department of Rehabilitation, Physiotherapy Science & Sports, Utrecht, Netherlands,

²Reade, Center for Rehabilitation and Rheumatology, Amsterdam, Netherlands, ³HU University of Applied Sciences Utrecht, Research Group Innovation of Human Movement Care, Utrecht, Netherlands, ⁴Vrije Universiteit Amsterdam, Department of Computer Science, Amsterdam, Netherlands, ⁵Maastricht University, Department of Health Promotion, Maastricht, Netherlands, ⁶Fontys University of Applied Sciences, Department of Health Innovations & Technology, Eindhoven, Netherlands

Purpose: Clinical guidelines recommend a stepped-care strategy for patients with hip and knee osteoarthritis (OA), starting with self-help approaches. However, the implementation of stepped-care remains limited. Digital self-management interventions have the potential to empower people while taking an active role in their OA management. Within the rapidly evolving field of digital health technologies, there is a growing need for solutions that adapt to individual patient needs over time. Artificial Intelligence (AI) offers new opportunities to deliver a personalized, just-in-time self-management intervention for people with OA. The development of such AI algorithms is limited due to a lack of rich, longitudinal datasets. Therefore, the objective of this study protocol is to collect data to develop data-driven models that support personalized recommendations on the optimal timing of self-care programs for individuals with hip and/or knee OA.

Methods: This prospective cross-over study aims to include 600 people with hip and/or knee OA, meeting the NICE criteria (ClinicalTrials.gov registration: NCT07423858). We aim to specifically include a subset of people with limited digital health literacy. Participants will be recruited across the Netherlands and will get access to the OsteoArthritisCoach. The OsteoArthritisCoach is a digital platform designed to collect data and to support behavioral change in OA with three self-care programs (i.e., physical activity promotion, weight management, and sleep optimization). Each participant will complete all three 12-week programs and one 12-week control period in a randomized sequence. The primary outcome for model development will be physical functioning over time. Secondary outcomes will be pain and participation. Additional measures include patient characteristics, physical activity, sleep, psychosocial factors, behavioral determinants, and engagement. The data will be used to develop models using supervised (causal) machine learning.

Results: This study protocol will provide data to develop data-driven models that forecast changes in physical functioning over time and support personalized recommendations on the optimal timing of specific self-care programs (physical activity promotion, weight management, and sleep optimization) for people with hip and/or knee OA.

Conclusion: These models will be integrated into a newly developed self-management app, the OsteoArthritisCoach version 2, to deliver just-in-time, personalized behavioral recommendations.

II-P-D.25

Assessing Satisfaction with the App-based Global Adolescents and Child Physical Activity Questionnaire (GAC-PAQ) among Spanish Children, Adolescents, and Caregivers

J. Brazo-Sayavera¹, G. Angulo-Garay², R. Larouche³

¹Universidad Pablo de Olavide, Department of Sports and Computer Science, Seville, Spain, ²Universidad Pablo de Olavide, Doctoral School, Seville, Spain, ³University of Lethbridge, Faculty of Health Sciences, Lethbridge, Canada

Purpose: The Global Adolescent and Child Physical Activity Questionnaire (GAC-PAQ) is a recently developed app-based questionnaire aimed at assessing physical activity in young populations. User satisfaction is a key determinant of acceptability in digital health tools, particularly among children and adolescents. The purpose of this pilot study was to assess satisfaction with the digital version of the GAC-PAQ among children/adolescents and their parents in Spain.

Methods: A descriptive and analytical cross-sectional pilot study was conducted with 64 participants, including children and adolescents (8–17 years) and their parents/guardians, recruited from two regions in Spain (i.e., Seville in the south and the Basque Country in the north), representing both rural and urban settings. After completing the digital GAC-PAQ, participants rated their overall satisfaction using a five-point emoji-based Likert scale, coded from 1 (lowest) to 5 (highest satisfaction).

Group comparisons of satisfaction scores were conducted according to participant type (children/adolescents vs. parents), age group (children vs. adolescents), sex, and geographical context (rural vs. urban). To compare groups, the Wilcoxon test or Kruskal-Wallis tests were applied, with statistical significance set at $p < 0.05$.

Results: Overall satisfaction with the digital GAC-PAQ was high across the total sample (4.62 ± 0.58). Non-parametric analyses revealed no statistically significant differences in satisfaction based on sex or generational group (children, adolescents, and parents). However, participants from rural areas reported significantly higher satisfaction than those from urban areas (4.78 ± 0.49 vs. 4.47 ± 0.62 ; $p = 0.020$). Similarly, satisfaction was significantly higher among participants from Seville versus the Basque Country (4.81 ± 0.40 vs. 4.44 ± 0.67 ; $p = 0.013$).

Conclusion: The findings support the high user satisfaction of the digital GAC-PAQ across diverse age groups, sex and locations, indicating broad usability. Although satisfaction remained consistently high across all participant subgroups, the statistically significant variations observed in urbanicity, and territorial origin suggest that geographic and sociocultural contexts may be associated with digital engagement. Consequently, while the tool demonstrates excellent overall acceptability across diverse settings, future large-scale implementations could explore these minor contextual nuances to further optimize adaptation and refine the user experience.

II-P-D.26

Development and Validation of an mHealth Nutrition and Lifestyle Education Package for Obesity Risk Reduction in Nigeria; A Digi-BB Trial Protocol

G.O. Iheme^{1,2}, B.F. Ortutu^{3,2}, F.C. Kalu⁴, F.C. Gideon-Iheme⁵, B.A. Onyeonu⁶, E.A. Oyebamiji⁷, A.F. Taiwo⁷, F.O. Samuel⁷

¹Uppsala University, Food Studies Nutrition & Dietetics, Uppsala, Nigeria, ²Michael Okpara University of Agriculture Umudike, Human Nutrition & Dietetics, Umuahia, Nigeria, ³Texas A&M University, Nutrition, Texas, United States, ⁴Michael Okpara University of Agriculture Umudike, Human Nutrition & Dietetics, Umudike, Nigeria, ⁵Abia State University Teaching Hospital, Medicine & Surgery, Aba, Nigeria, ⁶Federal University of Agriculture, Nutrition & Dietetics, Mubi, Nigeria, ⁷University of Ibadan, Human Nutrition & Dietetics, Ibadan, Nigeria

Purpose: The rising prevalence of Obesity among young people underscores the need for sustainable lifestyle interventions for weight reduction and overall health improvement. There is a lack of comprehensive, culturally-relevant, simplified and digitally compatible educational materials tailored for low-income settings. This study describes the systematic development and validation of a comprehensive mHealth educational curriculum designed to support a planned RCT intervention for young adults living with Obesity in Nigeria

Methods: A structured and visually-stimulating educational curriculum comprising 48 lessons was designed to be delivered twice every week, with accompanying quiz, reflections and monthly tasks. The nutrition module, accounting for one-third of the contents covered aspects of food literacy, portion control, ultra-processed foods, and emotional eating, while physical activity and other lifestyle behaviours were substantially integrated. During the formative development stage, a Delphi approach was employed within the Nutrition Drive for Healthy Diet (NDDI) network

D. E- & mHEALTH

to preliminarily strengthen the curriculum's quality. The refined version was then forwarded to experts and pilot participants for content and face validation, respectively. The selected experts, comprising health care professionals and researchers in related disciplines, and the pilot groups were pooled across all geopolitical zones. A web-enabled validation tool was developed using the Flutter programming framework selected for the mHealth application, allowing validators experience content delivery in a format aligned with the native app environment.

Results: The Delphi panel identified the curriculum's broad scope, strong evidence base, simplicity, and inclusion of ultra-processed food messaging as key strengths. However, reviewers highlighted the need for more nationally relatable examples and stronger alignment between visual elements and educational content. Outcomes of the in-progress content and face validation will be disseminated at the congress.

Conclusion: The mHealth Nutrition and Lifestyle education curriculum offers the potential to provide a feasible and evidence-based approach to supporting young adults' weight-loss journey through the adoption of health-promoting behaviours. The mHealth Nutrition and Lifestyle education curriculum offers the potential to provide a clear, feasible and evidence-based approach to support young adults' weight loss journey through the adoption of health-promoting behaviours. There is a need for rigorous validation and pilot of future intervention packages to strengthen the chances of success.

II-P-D.27

Feasibility, Acceptability, and Self-management Behavior Change Associated with CGM Use in Individuals with Early-onset Type-2 Diabetes

V. Castellanos-Ponce¹, E. Hernandez Mozo^{1,2}, F. Ronzon¹, R. Belasco³, S. Bagsic³, A. Philis-Tsimikas³, J. McCurley¹

¹San Diego State University, Psychology, San Diego, United States, ²SDSU/UCSD Joint Doctoral Program in Clinical Psychology, San Diego, United States, ³Scripps Health, San Diego, United States

Purpose: Early-onset type 2 diabetes (EOT2D) is increasing in prevalence and is associated with increased risk of diabetes complications and reduced life expectancy. Poor adherence to self-management behaviors is common among individuals with EOT2D, and few complete standard diabetes education programs. Continuous glucose monitors (CGMs) can support behavioral change and glycemic awareness but are underutilized among adults with EOT2D. This study aims to explore the feasibility and acceptability of CGM use, changes in glycemic awareness, and self-management behavior change among individuals with EOT2D using a CGM for the first time.

Methods: This study is enrolling adults aged 18-40 with a T2D diagnosis in the past 5 years, as documented in the electronic medical record of a California health system, and with no prior CGM use. Participants wear both a CGM and a FitBit watch for 30 days. A follow-up survey and qualitative interview are conducted to assess the acceptability and feasibility of CGM use, changes in glycemic awareness, and self-management behavior change. Qualitative data are transcribed, coded, and analyzed using structured thematic analysis.

Results: N = 14 of 40 participants have completed the study. Participant mean age is 35.4 (SD: 4.2) years, 57.1% are male, 50.0% are Hispanic, and 91.8% reported income that was below the median regional household income of \$100,000/year. Most participants felt confident using the CGM (85.7%), liked it (71.5%), found it easy to use (92.9%) and acceptable (92.9%), and wore it for the expected duration (100% wore ≥75% time). In qualitative interviews, participants reported increased glycemic awareness, improved confidence with self-management behaviors, improved understanding of the connections between diet, physical activity, and glucose, and changes in self-management behaviors (e.g., increased physical activity and healthy eating).

Conclusion: Preliminary findings indicate that CGMs are a feasible, acceptable, and well-liked tool for supporting glycemic awareness and behavior change among adults with EOT2D. Understanding behavior changes associated with CGM use combined with behavioral sensors (e.g., FitBit) will inform the design of optimal CGM-based self-management interventions for this high-risk population.

Understanding Implementation of Lifestyle Front Offices in the Netherlands: A Qualitative Causal Loop Diagram

A. Driessen¹, M. van Dijk¹, F. van Nassau¹, H. van der Ploeg¹, J. Jelsma¹

¹Amsterdam UMC, Public and Occupational Health, Amsterdam, Netherlands

Purpose: A healthy lifestyle is important in the treatment of non-communicable diseases. However, not all healthcare professionals offer lifestyle counseling due to several reasons. In the Netherlands, 23 hospitals have set up a Lifestyle Front Office (LFO) where patients will be guided in changing their lifestyle and when needed are referred to community-based lifestyle initiatives. However, all hospitals face challenges during the implementation process. Some evidence is known about facilitators and barriers for implementation of lifestyle interventions in a hospital setting. The aim of this paper is to identify leverage points for applying implementation strategies by mapping the current system in a Causal Loop Diagram (CLD) in order to better implement LFOs in the Netherlands.

Methods: Both qualitative interviews with healthcare professionals, as group model building sessions with project leaders of different lifestyle front offices were held to map barriers during implementation. The identified barriers were grouped into factors and incorporated into a CLD. These factors were then placed in a connection circle, where researchers examined potential causal relationships between them. Additional factors were added to the CLD when necessary to ensure the presence of feedback loops. The proposed causal links were subsequently reviewed and validated by other researchers.

Results: The following themes were found in the CLD: financial aspects, quality of care within the care pathway of the LFO, organization within the hospital and barriers concerning the target group. Within each theme leverage points were identified.

Conclusion: The current study highlights the importance of a systems perspective on implementation of interventions within a hospital setting. Implementers of LFOs can use the results to better understand where they could intervene in the system for a more sustainable implementation.

I-P-E.02

Do Effective Implementation Trials Receive Long-term Follow up and Does Effect Sustain? A Secondary Review of Prevention Programs in the School Setting

C. Gardner^{1,2,3}, A. Hall^{2,1,3}, C. Lane^{1,2,4}, N. Nathan^{1,2,4}

¹University of Newcastle, School of Medicine and Public Health, Newcastle, Australia, ²The National Centre of Implementation Science (NCOIS), University of Newcastle, Newcastle, Australia, ³Hunter Medical Research Institute, New Lambton Heights, Australia, ⁴Hunter New England Local Health District, Hunter New England Population Health, Wallsend, Australia

Purpose: Implementing health promoting programs in the school setting is a common approach to encourage physical activity and balanced nutrition early in life. However, if we are to improve population health, we need to ensure effective implementation is a precursor to long term delivery. This review uses innovative methods to explore program sustainment of effectively implemented programs and quantitatively assesses sustained implementation effect, in the school setting.

Methods: The sampling base of effectively implemented programs were sourced from a Cochrane systematic review of controlled implementation trials in schools (Wolfenden et al 2022). To identify follow-up studies, we conducted systematic forward citation searches of eligible trials in PubMed, SCOPUS, and Google Scholar. Eligible follow-up studies needed to collect comparable measures, at least 6 months after implementation supported ended and report findings quantitatively. Screening and data extraction were performed in duplicate. Long-term effect was calculated using a standard mean difference score for controlled studies, or a percentage of effect in intervention only follow-up.

Results: Citations relating to 23 effective implementation trials, produced 5483 unique papers for screening. Six studies were identified that had collected comparable effect data at a follow-up time (six months post implementation). Three studies addressed physical activity, two focused on nutritional behaviours and one targeted tobacco use. Four studies reported results compared to a control group. Four re-assessed implementation measures and two individual behavioural outcomes only. Sustained implementation effect was 51% to 122%, with a median of 76% (IQ1=56%, IQ3=107%).

E. IMPLEMENTATION AND SCALABILITY

Conclusion: This review shows few effectively implemented programs reported on sustained effect using the same rigorous methods as the implementation trial studies. It also suggests that effective implementation of school health programs can sustain some effect over time. However, the small and heterogeneous sample restricts our capacity to interpret or generalise these findings. To address this persistent gap, researchers should plan, conduct and disseminate trial findings at timepoints at least 12 months after implementation support has ended using comparable methods and rigor used during the trial. When synthesised, such findings can inform future program design to support the sustainment of effectively implemented programs.

I-P-E.03

Community Health Nurses' Acceptability of a New Sleep Intervention Supporting First-time Parents on Infant Sleep: A Mixed-methods Process Evaluation from the Bloom Study

R.R. Carlsson¹, M. Rasmussen¹, M.P. Jensen¹, L. Kierkegaard¹, T.R. Ubbesen¹, T.P. Pedersen¹, H.L. Ball², C.T. Bonnesen¹

¹National Institute of Public Health, Child and Adolescent Health, Copenhagen, Denmark, ²Durham Infancy & Sleep Centre, Durham University, Department of Anthropology, Durham, United Kingdom

Purpose: This ongoing process evaluation explores community health nurses' (CHNs) perceptions of acceptability of a new sleep intervention and its implementation strategies during the first year of implementation. The sleep intervention is part of the multicomponent Bloom Study and is integrated into the Danish community health nursing system to promote healthy weight development among infants and toddlers in first-time families in Denmark.

Methods: A convergent mixed-methods design combines focus groups and questionnaire data to obtain a comprehensive understanding of CHNs' perceptions of acceptability. This study is innovative in applying the Theoretical Framework of Acceptability (TFA) alongside a mixed-methods design to explore community health nurses' acceptability of the intervention components and implementation strategies in a real-world context. Both the interview guide and questionnaire are developed using the TFA, covering seven constructs of acceptability.

Two focus groups were conducted with CHNs from two Danish municipalities participating in the Bloom Study, with at least one additional group planned for 2026. Qualitative data will be analyzed using reflexive thematic analysis within an abductive approach, iterating between empirical data and TFA constructs to identify both theory-driven and emergent insights. The questionnaire, designed to quantitatively assess the seven TFA constructs, will be distributed to all participating CHNs (n = 134) in January 2026, and descriptive statistics will summarize acceptability scores. Integration of qualitative and quantitative findings will be guided by the TFA through a side-by-side joint display with meta-inferences.

Results: Preliminary qualitative findings identified three main themes influencing CHNs' perceptions of the sleep intervention's acceptability: (1) Need for knowledge and tools, (2) Believing in effectiveness, and (3) Confidence gained through training and guidance. The intervention was perceived to address a clear practice gap by providing evidence-based knowledge and concrete tools, fostered positive experiences with families, and strengthened CHNs' confidence through training and implementation support.

Conclusion: Preliminary results suggest that the sleep intervention was well-received and perceived as relevant, feasible, and supportive of CHNs' professional practice. Structured implementation support and opportunities for competence development appear central for sustaining engagement and ensuring successful integration into the community health nursing system.

I-P-E.05

Process Evaluation of a Randomised Controlled Trial Aimed at Improving Health Behaviours and Vitamin D Status during Pregnancy: Implementation of the SPRING Trial

S. Proebstl¹, C. Vogel^{2,3}, W. Lawrence², S. Strömmer², H. Inskip², J. Hammond², K. Hart², K. McGill², N. Harvey², M. Barker², J. Baird²

¹LMU Munich, Munich, Germany, ²University of Southampton, Southampton, United Kingdom, ³University of London, London, United Kingdom

E. IMPLEMENTATION AND SCALABILITY

Purpose: Globally, approximately 44% of pregnant women are affected by overweight or obesity. Maternal adiposity can adversely affect the health of the mother and her offspring, including increased risks for pregnancy complications and non-communicable diseases later in life. The Southampton PRenancy Intervention for the Next Generation (SPRING) evaluated two interventions to improve women's nutritional status during pregnancy: the behaviour change intervention 'Healthy Conversation Skills' (HCS) and vitamin D supplementation. This process evaluation aimed to assess the implementation of these interventions.

Methods: A total of 717 pregnant women were recruited from a maternity hospital in Southampton, UK, and randomised in a two-by-two factorial design. We collected quantitative data through questionnaires, case report forms, and audio recordings. We assessed the intervention's fidelity, dose, and reach descriptively. Using multiple linear regression models, we assessed HCS' effectiveness on diet quality, measured by a Food Frequency Questionnaire, and self-reported overall physical activity in participant subgroups.

Results: Our findings show that both interventions were delivered with high fidelity and participant compliance. The SPRING trial achieved a high retention rate (92%), however, women of lower socioeconomic status and those with less healthy behaviours were more likely to discontinue their participation. Women from ethnic minorities and those living in deprived areas were underrepresented among trial participants. During the Healthy Conversations, most women identified physical activity as their primary behaviour for change, while fewer focused on improving dietary quality. The dietary quality of these women did not show improvements but there appeared to be a marginally beneficial effect on physical activity, with the largest difference observed between the control group and participants with the highest exposure to Healthy Conversations (adjusted difference 0.16 SD (95%-CI -0.03; 0.34)).

Conclusion: This process evaluation offers insights to inform the interpretation of trial outcomes and the design of behaviour change and supplementation interventions during pregnancy. Engaging pregnant women in changing dietary behaviour proved more difficult than encouraging changes in physical activity. This might reflect both the challenges of diet-related change during pregnancy and the influence of unsupportive food environments. We also highlight the persistent difficulties in involving women from deprived backgrounds and ethnic minority communities in research.

I-P-E.06

Fostering Movement: A Feasibility Study of a School-based Intervention for Primary Children in Bangladesh

R.B. A. Ghani¹, W.C.P. Lau¹

¹Hong Kong Baptist University, Sports and Health Sciences, Hong Kong, Hong Kong, SAR of China

Purpose: Physical inactivity among children is a growing concern, particularly in Bangladesh. Globally only 10.3% of primary school children meet the 24-Hour Movement Guidelines. This study aimed to assess the feasibility, acceptability, and preliminary effectiveness of a school-based active play (AP) intervention designed to enhance all three components of movement behaviours among primary school children.

Methods: The pilot study was conducted at a selected primary school, involving 24 children recruited with the consent of their parents and teachers. Over four weeks, participants engaged in one-hour AP sessions twice a week after school. An orientation session for parents and teachers promoted AP during and after school, emphasising the use of safe outdoor spaces. Movement behaviours were assessed using structured questionnaires, the Global Physical Activity Questionnaire for Children (GPAQ-C), and waist-worn ActiGraphs over a seven-day period. Feasibility was evaluated through participation rates, achieving a retention rate of 75% (18 out of 24 children) by the endline assessment. Acceptability was measured through feedback collected via Likert scales and structured questionnaires. Intervention fidelity was maintained through the use of logbooks, fidelity checklists, and direct observations.

Results: Initial assessments revealed that 52.0% of participants engaged in active play for 30 to 60 minutes, while 41.7% reported less than 30 minutes of playtime. Endline results indicated a significant improvement in AP duration, with 36.8% now participating for 30 to 60 minutes and 55.6% engaging in AP for 60 to 120 minutes ($p < 0.05$). This shift reflects a statistically significant increase in both the frequency and duration of AP among participants. Feedback indicated high enjoyment levels, particularly for competitive activities, although some children expressed a preference for same-gender group formations. Parents recognised the positive impact on their children's PA levels but noted time management challenges, advocating for the integration of active play opportunities during school hours.

Conclusion: Despite discomfort with ActiGraphs in humid weather, the overall findings support the feasibility and acceptability of the intervention.

E. IMPLEMENTATION AND SCALABILITY

I-P-E.07

Adapting Primary Care-based Physical Activity Interventions: Protocol for a Sequential Exploratory Mixed Studies Review Using Topic Modelling

K. Wassef¹, T. Schuster¹, T. Barnett¹

¹McGill University, Department of Family Medicine, Montreal, Canada

Purpose: Physical activity interventions hold the potential to improve physical health and contribute to non-communicable disease prevention. However, these often need to be contextually tailored and adapted to clinic contexts and patient populations. Implementation researchers and clinicians lack clear guidance on how to adapt these interventions and what the most effective adaptation strategies are for their contexts. This review aims to assess the scope and effectiveness of strategies used to adapt physical activity interventions in primary care. The review will be guided by the question, “What strategies have been used to adapt primary care-based physical activity interventions and with what effect?”

Methods: We will apply a topic modelling approach to conduct a sequential exploratory mixed studies review. We will identify English and French primary studies and trial protocols from PubMed, Embase, CINAHL, and CENTRAL. Eligible articles describe and evaluate implementation strategies focused on adapting primary care-based interventions that promote physical activity or decrease sedentary behaviours among adults (aged 18-65) at risk of non-communicable disease. Topic modelling, an unsupervised learning method for analyzing text data, will be applied on eligible articles. This method employs Latent Dirichlet Allocation (LDA) to determine the probabilities of articles associated with given themes and how they relate in network graphs. We will use the Expert Recommendations for Implementing Change (ERIC) taxonomy for categorizing the strategies identified into themes. We will then use the Reach, Effectiveness, Adoption, Implementation, Maintenance (RE-AIM) framework to assess the effectiveness of strategies in terms of these dimensions.

Results: We expect to identify a range of strategies used to adapt primary care-based physical activity interventions. We found 47/73 ERIC strategies related to adaptation, of which we generated 102 terms to enable relevant mapping of topic distributions using LDA. We identified 816 unique records on PubMed. Using this test dataset, the preliminary LDA model produced visualizations of implementation outcome measures and intervention groups, including in rural communities.

Conclusion: To our knowledge, this is the first review of adaptation strategies used in primary care. Implementation scientists and primary care providers may consider these for effectively adapting physical activity and other health behaviour interventions to different settings, including underserved communities.

I-P-E.08

Burnley Outdoor Town: Operationalising a Cross-sector Vision for Physical Activity and Wellbeing through Place-based Implementation

E. Brady-Young¹, C. Goodman¹, P. Foster¹, A. Turner¹

¹Sport England, Together an Active Future, Burnley, United Kingdom

Purpose: The primary purpose of the study was to understand how system partners co-created the conditions for lasting physical-activity behaviour change at population level. It addressed three key research questions:

How do multi-sector partnerships develop a shared vision that aligns across agendas?

What mechanisms enable implementation and scale within a complex local system?

How can practice-based evidence inform wider policy on sustainable systems change?

Innovation lies in the use of developmental evaluation and realist methods within an applied setting to produce insights meaningful to both practitioners and policymakers, bridging the divide between real-world learning and academic evidence.

Methods: A developmental, practice-led evaluation was conducted between 2021 and 2025. Data were gathered from partnership workshops, reflective learning sessions, interviews with local leaders, and analysis of strategic documents. A realist-informed approach was used to identify context-mechanism-outcome (CMO) patterns explaining how system alignment and shared vision emerged. Iterative sense-making sessions ensured findings were tested and refined with stakeholders in real time.

E. IMPLEMENTATION AND SCALABILITY

Results: Implementation produced both mechanistic insights and system-level outcomes:

1. System coherence and shared purpose: partners co-created a collective vision and cross-sector strategy, positioning the outdoors as a policy and wellbeing asset.
2. Distributed leadership and embedded capacity: new funded roles and governance structures were established within local organisations.
3. Policy and investment alignment : the Outdoor Town vision became integrated into Burnley's Strategic Plan, Cultural Framework, Green Infrastructure Strategy.
4. Relational learning infrastructure: the Forum evolved into a self-sustaining learning network, fostering iterative practice, evidence generation, and shared accountability.

Conclusion: This learning highlighted both the potential and the challenges of developmental, practice-led research in complex systems. While this approach generated timely insights that directly shaped local strategy and investment, it also operated within policy environments that often prioritise quantitative evidence and standardised metrics. Demonstrating impact through traditional measures proves difficult, as learning and adaptation occurred in real time rather than through fixed endpoints. Additional challenges included managing shifting system boundaries, sustaining engagement across sectors. Yet these tensions became part of the learning process itself, illustrating that when evidence and action evolve together, evaluation can strengthen the culture of collaboration that underpins long-term systems change.

I-P-E.09

Outcomes of a Community-engaged Implementation Mapping Process to Design Equity-focused Implementation Strategies for Universal School Meals

G. McLoughlin¹, A. Smith¹, D. Kulkarni¹, S. Dubrin-Meneses¹, R. Jones^{2,3}, O. Martinez⁴, A. Dopp⁵, S. Kumanyika⁶, R. Brownson^{7,8}, J.O. Fisher¹

¹Temple University, Social and Behavioral Sciences, Philadelphia, United States, ²Temple University, Epidemiology and Biostatistics, Philadelphia, United States, ³Temple Health, Fox Chase Cancer Center, Philadelphia, United States, ⁴University of Central Florida, School of Medicine, Orlando, United States, ⁵RAND, Santa Monica, United States, ⁶University of Pennsylvania, Perelman School of Medicine, Philadelphia, United States, ⁷Washington University in St. Louis, Prevention Research Center, St. Louis, United States, ⁸Washington University in St. Louis, Alvin J. Siteman Cancer Center, St. Louis, United States

Purpose: Improving child food security and dietary intake among low-income, racial and ethnic minority populations can mitigate inequities in chronic disease risk such as obesity, diabetes, and cancer. Universal School Meals (USM) policies in the U.S. allow schools serving low-income populations to provide free breakfast and lunch to all students, showing promise for improving health and education outcomes. However, implementation challenges—such as stigma and funding constraints—persist. To address this issue, this study aimed to 1) engage in an Implementation Mapping process in collaboration with a low-income urban school district in the United States, and 2) collaboratively design implementation strategies grounded in health equity principles.

Methods: In the 2024-2025 academic year we began a pilot hybrid type III implementation-effectiveness trial with 4 schools in the School District of Philadelphia (2 intervention, 2 waitlist) and our community advisory board. Intervention schools formed implementation teams of teachers, staff, students, and parents and completed several Implementation Mapping tasks: (i) conducted needs and assets assessment and identify adopters and implementers, (ii) identified implementation outcomes, equity-related performance objectives (iii) created equity-driven implementation strategies, and (iv) produced implementation protocols; strategies were operationalized according to the Implementation Strategies Applied in Communities compilation.

Results: Across both intervention schools, we engaged 19 participants (3 teachers, 2 food service, 2 parents, 2 administrators, 10 students) and 10 district/external staff in the mapping procedure. Strategies developed by intervention schools included Identify Champions (teachers and/or students as ambassadors), Engage Community Members (menu promotion), Use Formal Agreements with Partners (food educators), Change Adaptable Program Components (new flavors), Create Program Guide (implementation protocols), and Facilitate Implementation (technical support). School teams and researchers collaborated to develop equity-focused evaluation protocols to examine potential impact on equitable implementation and health impacts of USM.

Conclusion: By integrating structured, theory-based methods with genuine community partnership, this approach provides a replicable roadmap for other public health and education settings seeking to close the gap between policy and equitable practice. Future phases of this hybrid trial will assess not only the effectiveness of the strategies but also their scalability, sustainability, and impact on reducing disparities in food security and health outcomes among vulnerable youth.

E. IMPLEMENTATION AND SCALABILITY

I-P-E.10

Implementation Strategies Applied in Communities Matching Process (ISAC Match): Expanded Guidance and Case Study

L. Balis¹, T. Massey-Swindle^{2,3,4}, S. Palmer¹, E. Shaw¹, S. Jones-Dozier⁵, M. Grocke-Dewey^{6,5}

¹Center for Nutrition & Health Impact, Omaha, United States, ²University of Arkansas Medical Sciences, Department of Pediatrics, Little Rock, United States, ³Arkansas Children's Nutrition Center, Little Rock, United States, ⁴Arkansas Children's Research Institute, Little Rock, United States, ⁵Montana State University, Extension, Bozeman, United States, ⁶Montana State University, Department of Human Development and Community Health, Bozeman, United States

Purpose: Limited guidance exists on feasible processes for selecting and tailoring implementation strategies in community settings. The recently developed Implementation Strategies Applied in Communities (ISAC) compilation includes a pragmatic matching process (ISAC Match). The purpose of this study is to expand on ISAC Match by providing additional detail and a case study example.

Methods: ISAC Match includes four steps: 1) reviewing available information on intervention integration and conducting contextual inquiry, if needed, to understand barriers and facilitators; 2) identifying existing implementation strategies used in the implementing organization, 3) using ISAC guidance tools to select relevant implementation strategies to overcome barriers and capitalize on facilitators; and 4) tailoring strategies to fit within the setting. These steps are completed with health equity considerations in mind to ensure that implementation strategies are designed to improve adoption, implementation, and maintenance in ways that seek to narrow health disparities. This study applied the ISAC Match process to select and tailor implementation strategies to increase Montana State University Cooperative Extension Agents' adoption of built environment approaches that facilitate physical activity. This was conducted through an Integrated Research-Practice Partnership composed of Agents and researchers.

Results: Step 1: A previous contextual inquiry study and a "walking vote" were used to prioritize barriers facilitators. Step 2: A facilitated discussion was used to identify existing implementation strategies to overcome barriers. Step 3: Potential implementation strategies following the ISAC guidance tool were reviewed. Twelve were selected and rated for importance and feasibility on 5-point Likert scales. Five strategies had mean ratings of 4.0 or higher for both feasibility and importance; they were consolidated into three implementation strategies to test (technical assistance, guidebook, and funding support). Step 4: A brainwriting premortem activity was used to tailor strategies; most suggestions aimed to improve feasibility, were related to modifying content, and were fidelity consistent.

Conclusion: The case study presented here describes the use of ISAC Match in one community setting with one type of intervention. Future work is needed across settings and interventions to determine whether the strategies selected through ISAC Match are effective in improving adoption, implementation, and maintenance.

I-P-E.11

Using Implementation Science to Assess Stakeholders' Perspectives on the Innovation, Implementation, and Sustainability of an Enhanced Home Delivered Meal Program (Meals+)

G. Oladeji¹, C. Caspi¹, K. Thomas², I. Costa da Silva¹, B. Tyler¹, M. Noonan¹, K. Gans¹

¹University of Connecticut, Storrs, United States, ²Johns Hopkins University, Baltimore, United States

Purpose: Nutrition insecurity and social isolation are public health priorities among older adults. Meals+, an enhanced home-delivered meal program (HDMP), augments traditional Meals on Wheels of RI (MOWRI) services with monthly supplemental grocery bags and community health worker calls to address these problems. Understanding baseline contextual factors is critical for intervention implementation planning and sustainability. This study explored stakeholders' perspectives on Meals+, including barriers and facilitators, using implementation science frameworks.

Methods: We conducted baseline qualitative interviews with five internal stakeholders (MOWRI) and 12 external stakeholders. Transcripts were coded using a deductive-inductive thematic analysis approach. Data analysis and interpretation were guided using the Practical, Robust Implementation and Sustainability Model and the Consolidated Framework for Implementation Research, focusing on inner/outer settings, innovation characteristics, and implementation and sustainability infrastructure domains. Stakeholders also completed an adapted Program Sustainability Assessment Tool (PSAT) survey assessing organizational capacity across sustainability domains.

Results: Regarding innovation characteristics, internal stakeholders broadly viewed Meals+ as a natural extension of

E. IMPLEMENTATION AND SCALABILITY

traditional HDMPs. Most stakeholders emphasized the intervention's perceived fit and relative advantage, particularly its potential to enhance socialization and supplement existing community services. Concerns were raised about potential duplication with other grocery delivery programs.

Internal stakeholders expressed strong enthusiasm and readiness, citing a dedicated internal team, integration with existing organizational services, and mission alignment as key facilitators. Outer setting factors included the political and financial climate and revealed mixed perceptions among stakeholders. Stakeholder recommendations for implementation and sustainability included establishing robust case management systems, coordinating cross-sector partnerships and communication among community partners, and forming advisory committees. Stakeholders also advocated tailoring grocery delivery based on in-person or telehealth assessments of participants' needs.

PSAT findings supported qualitative themes. Across combined stakeholder responses, adaptability (mean = 6.06), communication (mean = 6.09), and strategic planning (mean = 6.08) were rated highly on a 7-point Likert scale, while funding sustainability scored moderately (mean = 5.61).

Conclusion: Findings reveal facilitators, including strong organizational readiness and enthusiasm for Meals+, alongside the perceived positive impact of the innovations. Embedding sustainability strategies early — leveraging internal strengths and addressing external financing barriers — will be essential for long-term success.

I-P-E.12

Implementing Produce Prescriptions for Adults with Type 2 Diabetes: A Multi-site Qualitative Study Guided by the Exploration, Preparation, Implementation, Sustainment (EPIS) Framework

S. Stotz¹, E. Mitchell², J. Marriott², D. Nugent³, C. Byker Shanks²

¹Colorado State University, Food Science and Human Nutrition, Fort Collins, United States, ²Center for Nutrition and Health Impact, Omaha, United States, ³Independent Consultant, Deale, United States

Purpose: Socioeconomic inequities shape access to healthy foods and diabetes outcomes. To address this, Produce Prescription (PPR) programs, which allow clinicians to “prescribe” fruits and vegetables to patients experiencing food insecurity, show promise but remain under-studied from an implementation science perspective. This multi-site qualitative study applied the Exploration, Preparation, Implementation, Sustainment (EPIS) framework to identify contextual factors influencing feasibility, fidelity, and sustainability of PPR delivery within the Pathway for Produce Prescriptions in Type 2 Diabetes (PPPT2D) initiative.

Methods: Pre- and post-PPPT2D implementation interviews were conducted with clinic and community-based partner leadership and staff at five sites throughout the U.S. (n=13 pre; n=18 post). Semi-structured moderator guides explored EPIS phases. Transcripts were analyzed thematically using both inductive and deductive approaches.

Results: Key themes aligned with EPIS phases.

Exploration: Partners recognized the urgent need to address diet-related diabetes disparities and viewed PPR as a tangible “food-as-medicine” strategy. Motivation stemmed from community demand and prior success with PPRs, yet outer-context barriers such as complex IRB processes, contracting delays, and fragmented funding created early uncertainty.

Preparation: Building inner-context capacity was essential. Sites developed electronic referral workflows, staff training, and coordination systems but cited turnover and limited protected time as persistent challenges. Bridging relationships with food access partners (e.g., farmer networks, grocers) enhanced readiness through shared logistics planning.

Implementation: Program delivery required ongoing adaptation. Clinics navigated workforce instability, complex data-sharing, and variable participant engagement. Success hinged on having a “PPR champion,” building and sustaining strong partnerships between multisector collaborations with aligned priorities, and compensating dedicated PPR staff.

Sustainment: Partners emphasized integrating PPR processes into standard workflows (e.g., embedding referrals into electronic medical records) and advocated for mechanisms to ensure long-term funding. Many planned to leverage outcome data to maintain and adjust relevant partnerships and scale implementation.

Conclusion: Applying the EPIS framework showed that sustaining PPR programs depends on strengthening inner-context infrastructure (staffing, leadership engagement), streamlining outer-context systems (funding and regulatory alignment), and supporting bridging relationships that anchor multisector collaboration. EPIS provided a useful lens for understanding how PPR programs can be implemented and scaled as equitable, systems-level approaches to diabetes management.

E. IMPLEMENTATION AND SCALABILITY

I-P-E.13

Physical Activity Intervention Development and Evaluation: A Five-step Plan Applying Multi-process Action Control

C. Brennan¹, H. Hollman¹, R. Rhodes¹

¹University of Victoria, Behavioural Medicine Lab, Victoria, Canada

Purpose: There is a pressing need for effective theory-based interventions that promote the initiation, sustained engagement, and long-term maintenance of physical activity (PA). Although intervention development frameworks suggest grounding interventions in behaviour change theory, practical guidance on how to do so remains limited. This paper presents a five-step plan to harmonise the use of behaviour change theory in intervention development and evaluation, conceptually aligned with established intervention development frameworks, and illustrated using Multi-Process Action Control (M-PAC) as an example. M-PAC explains and predicts how PA is initiated, enacted, and maintained over time through three interrelated processes (reflective, regulatory, and reflexive).

Methods: A critical review of the literature was conducted to examine intervention development frameworks, guidance on theory use in intervention design, and reviews of theoretical approaches to behaviour change. Through iterative synthesis, the review team reached consensus on what is commonly addressed (e.g., calls for greater conceptual and methodological innovation in health behaviour change research) and what remains absent (e.g., explicit steps for operationalising theory in intervention design) across frameworks and theories. Drawing on these findings, a five-step plan was developed to guide researchers in grounding interventions in behaviour change theory and applied to M-PAC.

Results: The five step plan consisted of: (1) Formative Research: understanding behavioural context and behaviour science theory in relation to population and context, (2) Design: selecting behaviour change techniques mapped to reflective, regulatory, and reflexive processes, identifying mode-of-delivery, and developing an M-PAC logic model, (3) Assessment: selecting and testing validated M-PAC measures and ecological momentary assessment items. (4) Process Evaluation: examining fidelity, mechanisms, and context, including qualitative M-PAC exit interview guides, and (5) Knowledge Mobilisation: translating evidence into practice and policy. Each step embeds integrated knowledge transfer with knowledge users (e.g., participants, practitioners, educators, clinicians, and policymakers).

Conclusion: The five-step plan provides a standardised and practical approach for the development and evaluation of M-PAC-based interventions and may inform the development of approaches for other theoretical frameworks. The plan advances intervention science by bridging theory and practice through a systematic, theory-driven, and adaptable process that strengthens theoretical fidelity, reproducibility, and real-world impact.

I-P-E.14

Implementation of a Lifestyle Front Office for Obstetrics and Fertility Patients and Gastroenterology Patients in a Dutch Hospital: A Process Evaluation

A. Driessen¹, J. Marks-Vieveen¹, M. van Dijk¹, H. van der Ploeg¹, A. van der Beek¹, K. Stronks¹, A. de Jonge², J. Bont³, J. Erdmann⁴, R. Painter⁵, J. Jelsma¹

¹Amsterdam UMC, Public and Occupational Health, Amsterdam, Netherlands, ²Amsterdam UMC, Midwifery Science, Amsterdam, Netherlands, ³Amsterdam UMC, Huisartsgeneeskunde, Amsterdam, Netherlands, ⁴Amsterdam UMC, Maag-, Darm- en Leverziekten, Amsterdam, Netherlands, ⁵Amsterdam UMC, Verloskunde & Gynaecologie, Amsterdam, Netherlands

Purpose: A lifestyle front office (LFO) was set up in a Dutch hospital, a new care model that refers hospital patients towards community based lifestyle initiatives (CBLI). The implementation of this new care model was investigated in the current study, in the care pathway of obstetrics and fertility (Gyn) patients on one hand and Gastroenterology (GE) patients on the other hand.

Methods: We conducted a mixed methods process evaluation using the UK MRC guidelines. Quantitative data was obtained from patients electronic health records, patients and healthcare professional (HCP) questionnaires. Qualitative data was obtained via patients and HCP questionnaires and interviews. A semi-structured interview guide was used and analyzed deductively using a pre-defined codebook that followed the structure of the interview topic guide.

Results: The study showed the following results according to the UK MRC guidelines. *Context:* 32% of patients visiting the GE and Gyn department reported at least one unhealthy behavior. *Recruitment:* Patients heard about the LFO mainly via their health care professional (79.8%) and Health care professionals were familiarized with the LFO via

E. IMPLEMENTATION AND SCALABILITY

their colleagues (73.7%) or via presentations at their department (52.6%). *Delivery*: 56.6% of patients were referred to a CBLI and 78% worked on their lifestyle behavior, as discussed with the lifestyle broker. 78% of HCPs discussed the LFO with their patients. *Reach*: 868 patients were referred to the LFO from March 2022 till December 2024, with 780 first consults. 122 unique HCPs referred patients to the LFO. *Mechanisms of impact*: Patients rated the conversation at the LFO with an 8.0. HCPs scored the LFO as important and therefore should continue well into the future.

Conclusion: This study highlights the potential of an LFO in a hospital setting. Future research should further investigate implementation strategies on referral of patients to the LFO and objectively investigate effectiveness for behavioral change.

I-P-E.15

Expert Insights on High-quality Multi-site Data Collection on Physical Activity Behaviours: A Preliminary Analysis

A. D'Sa¹, F. van Nassau², A. Lane¹, K. Dowd¹

¹SHE Research Centre, The Technological University of the Shannon, Department of Sport and Health Sciences, Athlone, Ireland, ²Amsterdam Public Health Research Institute, Amsterdam UMC, Department of Public and Occupational Health, Amsterdam, Netherlands

Purpose: Physical inactivity remains a significant public health concern globally. To inform evidence-based practice and policy, high-quality data on physical activity behaviours (i.e., prevalence, trends and determinant identification) is required. Harmonised multi-site data collection (MSDC) allows for larger, comparable datasets to be analysed, thereby increasing study power and the reliability of findings, helping to inform national and international policy and practice. However, difficulties in co-ordinating MSDC arise from differences in planning and implementation of approaches across sites. This study aimed to gather expert insights into factors influencing high-quality MSDC of physical activity behaviours.

Methods: Semi-structured online interviews were conducted with experts who have led large-scale MSDC for physical activity behaviours. Experts were identified through a systematic search of relevant projects, and invited via email to participate in a 60-minute interview. Interviews were audio-visually recorded, transcribed verbatim, and coded using MAXQDA. A reflexive thematic analysis was used to identify common themes and patterns.

Results: Twelve experts were interviewed between May and October 2025. Most were part of multi-site studies across Europe (n=6), four had experiences with global MSDC, and two had experience with MSDC within one European country. Key facilitators of high-quality data collection included team confidence, in-person collaboration, thorough training, and pilot testing. Research fatigue emerged as a recruitment barrier, with experts highlighting the importance of creating a supportive environment for data-collection to encourage participation. Data collection methods varied (online vs paper-based), however, were often processed centrally. Multi-level quality checks and various researcher-based resources (i.e., videos, stepped guides) were found to support data quality. Experts emphasised the importance of flexibility, back-up plans to mitigate challenges, and the presence of trained senior staff during data collection. Finally, establishing clear guidelines for handling ethics applications, dissemination of findings, and decision-making hierarchies can facilitate effective multi-site collaboration.

Conclusion: This study provides practical insights into challenges of conducting MSDC. Findings support the development of procedures to ensure consistency and quality in MSDC. Further providing practical guidance for future large-scale public health studies, promoting harmonised high-quality data to better inform interventions and policy.

Using Implementation Mapping to Optimize Health Impacts of the Universal School Meal (USM) Provision in a Low-income, Urban School District: An In-depth Qualitative Analysis

G. McLoughlin¹, A. Smith¹, D. Kulkarni¹, S. Dubrin-Meneses¹, G. Adhikari¹, R. Jones^{2,3}, S. Viruduchalam⁴, J. Deutsch⁵, I. Hong⁶, H. Eisenstein⁷

¹Temple University, Social and Behavioral Sciences, Philadelphia, United States, ²Temple University, Epidemiology and Biostatistics, Philadelphia, United States, ³Temple Health, Fox Chase Cancer Center, Philadelphia, United States, ⁴Children's Hospital of Philadelphia, Department of Pediatrics, Philadelphia, United States, ⁵Drexel University,

E. IMPLEMENTATION AND SCALABILITY

Department of Food and Hospitality Management, Philadelphia, United States, ⁶Northeast High School, Philadelphia, United States, ⁷University of Pennsylvania, Philadelphia, United States

Purpose: Childhood obesity and food insecurity disproportionately impact Black and Latino students in Philadelphia, United States. Universal school meals (USM) serve as a first line of defense for students facing hunger. Despite this, uptake remains low across the district. Community-led interventions and strategies are an underutilized approach but may yield a more sustainable impact on addressing food insecurity. The aims of this study were to: 1) engage in a structured implementation mapping process with a diverse array of school and district representatives grounded in implementation science and health equity frameworks and 2) understand the key constraints and supports of implementation mapping through policy implementer and recipient perspectives.

Methods: Within a hybrid type III implementation-effectiveness trial, we recruited 4 schools (2 intervention, 2 waitlist) to engage in the mapping process. Meetings covered tasks 1-4: task 1) needs assessment, 2) identify objectives, 3) select strategies, and 4) prepare implementation plan over 4-5 planning meetings in partnership with school food service, students, parents, teachers, and administrators of each school. Transcripts were coded deductively using the Exploration, Preparation, Implementation and Sustainment (EPIS) and Getting to Equity (GTE) frameworks and inductively by the research team.

Results: We engaged 19 participants (3 teachers, 2 food service, 2 parents, 2 administrators, 10 students) and 10 district/external staff in the mapping procedure. Qualitative extracts (N=3042 codes) were primarily coded to Culture (n=132) from the EPIS framework and Increase Healthy Options (n=178) from the GTE framework. Code relations analysis between both frameworks highlighted factors such as school and district operations and social drivers of health among school communities that impact equitable USM implementation. Inductive coding yielded four primary themes of communication, social structure, autonomy and decision making, and infrastructure/material barriers, with subthemes to highlight the facilitators and barriers to implementation mapping and changing USM on a systems level.

Conclusion: Engaging school and district partners is an essential step for building lasting change in health of underrepresented communities. We engaged a diverse array of representatives in implementation mapping and facilitated development of implementation strategies. This is one example of how community-partnered research can be leveraged to produce long-lasting change in school systems.

I-P-E.17

Development of a Nutrition Care Pathway for Individuals with a History of Gestational Diabetes Mellitus: Preliminary Results

I. Auclair Mangliar¹, C. Simoneau², É. Carbonneau^{3,2}, A.-S. Morisset^{1,3,2}, S. Desroches^{3,2}, J. Robitaille^{1,3,2}

¹Centre de Recherche du CHU de Québec-Université Laval, Axe Endocrinologie et Néphrologie, Québec, Canada,

²Université Laval, Centre Nutrition, Santé et Société (NUTRISS) de l'Institut sur la Nutrition et les Aliments Fonctionnels (INAF), Québec, Canada, ³Université Laval, École de Nutrition, Québec, Canada

Purpose: Gestational diabetes mellitus (GDM) affects around one in ten pregnancies in Canada and has lasting health impacts. While nutrition counseling is provided for GDM-complicated pregnancies, no systematic postpartum follow-up is available in the province of Quebec, despite evidence that a healthy diet is essential to prevent type 2 diabetes and cardiovascular disease. The project aims to: 1) develop and implement a nutrition care pathway for individuals with a history of GDM; 2) evaluate the implementation of the nutrition care pathway using indicators to report on feasibility, adoption, and acceptability.

Methods: A nutritional consultation within a hospital setting is being offered to 500 individuals ≥ 18 years who have been diagnosed with GDM and given birth at the CHU de Québec. At 2 months after the estimated due date, participants complete a web-based 24-hour dietary recall (R24W) and other web-based questionnaires (eating practices, perceived risk, self-efficacy), followed by a nutrition consultation (in-person or via teleconsultation). At 6-months postpartum, participants complete the R24W and the questionnaires again. Implementation is being evaluated by quantitative and qualitative indicators collected through participant questionnaires, feedback and program monitoring.

Results: Since recruitment began (March 2025), postpartum nutrition consultation was offered to 192 individuals at their last nutrition consultation during pregnancy, with 78% (n=149) expressing interest. A total of 116 individuals were reached and 76% (n=90) consented to participate in the project. So far, 30 participants have completed the questionnaires and nutritional consultations began at the end of June 2025. Preliminary results (n=30) indicate that 84% believe they have a low to moderate risk of developing type 2 diabetes in the next 10 years, suggesting lack of awareness. Despite 97% recognizing the importance of adopting healthy eating habits and 83% feeling motivated to do so, postpartum nutrition consultations revealed suboptimal diets. In terms of adoption, 90% chose a teleconsultation

E. IMPLEMENTATION AND SCALABILITY

follow-up, as opposed to in-person, and 63% completed R24W.

Conclusion: Gaps in diet quality and diabetes risk awareness, combined with the absence of systematic postpartum follow-up, highlights a need for structured nutrition guidance. This project is a first step towards implementing a postpartum nutrition care pathway for people with GDM-complicated pregnancies.

I-P-E.18

Sustaining Food Is Medicine Programs: Evidence from Multi-site Food Bank – Healthcare Partnerships across the United States

B. Houghtaling¹, E. Short¹, C. Long¹, E. Anderson Steeves¹, L. Flournoy¹, M. Isack¹, G. Talavera¹, P. Kramer², E. August², A. Berry², N. Cawrse¹, E. Calloway¹

¹Center for Nutrition & Health Impact, Omaha, United States, ²Feeding America National Organization, Chicago, United States

Purpose: Food is Medicine (FIM) programs are complex interventions delivered in partnership with healthcare that identify patients with limited income and diet-related chronic disease risk and provide access to nutritious food. Despite substantial investment and promising outcomes emerging globally, evidence on FIM implementation and long-term viability is limited. This study aimed to address this gap.

Methods: A national cohort of twenty-one FIM food bank grantees and their healthcare partners could participate. The abbreviated Program Sustainability Assessment Tool (PSAT) was administered to food bank grantees, which uses a 7-point scale across eight constructs (higher numbers indicate increased capacity for sustainment): Environmental Support, Partnerships, Organizational Capacity, Funding, Evaluation, Adaptation, Communications, and Strategic Planning. The survey also captured implementation strategies used by food banks following standard compilations and included open-ended items. A separate survey was administered to healthcare partners using the comparable Clinical Sustainability Assessment Tool (CSAT) and open-ended questions. All survey terminology was adapted with partners for content validity. Structured notes about implementation successes and challenges from two years of grantee meetings were used to triangulate and supplement survey data.

Results: Twenty food bank grantees and twenty-eight healthcare partners associated with fourteen food banks responded to surveys. The total mean PSAT score was 5.2 (± 0.53) out of a possible 7, ranging from 3.4 (± 1.5) to 6.4 (± 1.1) across food banks. The Environmental Support construct scored highest; Partnerships scored the lowest. Most food banks (81%) reported needing additional resources for FIM implementation/sustainment, including financial ($n=15$), technical assistance ($n=11$), and staffing ($n=7$). All grantees reported providing technical assistance ($n=20$) to support FIM implementation, with many also using fidelity checks and trainings; fewer incentivized staff. The total mean CSAT score across healthcare partners was 5.49 (± 0.60) out of 7. Organizational Readiness for FIM was rated lowest; Engaged Partners was rated highest. Fifteen reported needing additional resources. Implementation notes offered deeper insight into PSAT/CSAT scores from the food bank perspective, including partnership challenges/successes.

Conclusion: Grantee sustainability reports highlighting organizational strengths and challenges to inform planning were shared with food banks. Results offer critical insight into FIM implementation and sustainability opportunities for researchers, practitioners, and policymakers globally.

I-P-E.19

Dose-response Association between Wearables-quantified Incidental Physical Activity and Type 2 Diabetes

A. Sabag¹, R. Kishore Biswas¹, N. Koemel¹, E. Stamatakis¹, M. Ahmadi¹

¹The University of Sydney, Faculty of Medicine and Health, Sydney, Australia

Purpose: To determine the dose-response associations between intensity-specific incidental physical activity (IPA) and the incidence of type 2 diabetes (T2D) among adults in the UK.

Methods: Study participants included adults from the UK Biobank accelerometry sub-study who self-reported as non-exercisers. Participants were excluded if, at baseline, they had T2D, were undergoing insulin therapy, or were diagnosed with T2D within 12 months of follow-up. T2D diagnosis was primarily obtained from self-reports and primary care records. Device-captured IPA duration was categorised into light, moderate, and vigorous (LIPA, MIPA

E. IMPLEMENTATION AND SCALABILITY

and VIPA). Additional analyses determined the T2D-specific equivalence of one minute of VIPA against MIPA and LIPA. The reference group included participants who did not engage in MIPA or VIPA.

Results: The primary analysis included 22,857 non-exercisers (mean age 62.1±7.7 years, 42.8% male). Over a 7.9-year follow-up period, 721 (3%) participants developed T2D. MIPA and VIPA, but not LIPA, exhibited near-linear inverse associations with T2D risk. Median VIPA (4.75 min/day) was associated with a HR 0.62 (95%CI:0.53–0.73), and median MIPA (23.70 min/day) showed a HR of 0.67 (95%CI:0.52–0.86). One minute of VIPA/day was equivalent to the T2D risk reduction of 5.9 min MIPA/day and 54 min LIPA/day.

Conclusion: Both MIPA and VIPA were associated with a lower risk of T2D in a dose-dependent manner, with one minute of VIPA equivalent to 5.9 min of MIPA or 54 min of LIPA. Whilst the median LIPA was associated with a reduced risk of T2D, there was no clear dose–response association.

I-P-E.20

Adapting a Food Retail Evidence-based Program for Latinos Living in Rural Communities: The Nuestro Valor Study

K.K. Hara-Hubbard¹, M. Flores Moreno¹, E. Grijalva-Martinez¹, A. Hernandez¹, M. Sanchez¹, L. Rios², D. Diaz², S. Guadarrama¹, J. Valencia¹, E. Torres², G.X. Ayala³, I. Ornelas¹, P.A. Hannon¹, B. Bekemeier¹, B. Baquero¹

¹University of Washington, Seattle, WA, United States, ²Northwest Communities Education Center/Radio KDNA, Granger, WA, United States, ³San Diego State University, San Diego, CA, United States

Purpose: For Latinos living in rural areas of the United States, structural inequities lead to limited access to fresh produce and unhealthy dietary behaviors. To address these gaps, we must accelerate the implementation of effective community-level interventions. Nuestro Valor is a culturally grounded food-retail intervention that promotes produce purchasing and consumption through a stipend to upgrade store (tienda) produce displays, specialized staff training, and a customer-directed point-of-purchase (POP) campaign. Partnering with a community-based organization (Radio KDNA), we adapted the Nuestro Valor intervention to be delivered by community health workers (CHWs) to Latinos shopping in rural tiendas.

Methods: Grounded in the Framework for Reporting Adaptations and Modifications-Enhanced (FRAME), we used convergent mixed methods to inform intervention adaptations. FRAME guides what to adapt, decision-making processes for adaptations, and informs adaptation monitoring and documentation. Radio KDNA CHWs conducted tienda customer and manager surveys while researchers hosted CHW focus groups to interpret survey results and inform intervention adaptations.

Results: Together we completed 100 customer intercept surveys, 13 manager surveys, and 3 focus groups. Nearly 1 in 4 customers used food assistance programs, so we adapted the tienda stipend to support Point of Sale systems that can track produce sales. Ninety-two percent of managers believed staff recommendations influenced customers' shopping decisions, yet 85% indicated staff business was a barrier to offering Nuestro Valor, so we shortened staff trainings, maintaining a focus on customer service and marketing. Managers (72%) and customers (77%) indicated that food demonstrations influenced customers' purchasing; as a part of the POP campaign, we will encourage staff to bundle "ready to cook" meals with healthy food demonstrations. Only one manager had worked with CHWs and the CHWs discussed limited experience working with businesses, so intervention implementation training for CHWs now includes strategies for building relationships with managers and staff.

Conclusion: Our community-engaged approach integrates implementation methods and participatory science to ground the intervention's adaptation and implementation. We are now testing the adapted intervention in a cluster randomized trial with tiendas in Washington State. Other researchers and practitioners could apply the FRAME and our community partnership approaches to adapt evidence-based interventions for new settings or populations.

I-P-E.21

Fueling Station Smoothies as a Real-world, Scalable Strategy to Improve Diet Quality in Division I Athletes

R. Higginson¹, K. Ward², A. Tanner², A.H. Redelfs²

¹Brigham Young University, Athletics, Performance Nutrition, Provo, Utah, United States, ²Brigham Young University, Public Health, Provo, Utah, United States

E. IMPLEMENTATION AND SCALABILITY

Purpose: Adequate fruit and vegetable (F&V) intake supports health, performance, and recovery in athletes, yet their diets are inadequate. This study is the first to integrate biomarker verification in a real-world environmental nutrition intervention to increase access to and consumption of F&Vs among NCAA Division I athletes.

Methods: A repeated-measures observational approach evaluated implementation and outcomes of a daily green smoothie intervention on collegiate student-athletes at an NCAA Division 1 university. A total of 70 athletes consented (54% female, 93% white) from 14 sports. Randomization was not feasible due to team schedules and operational constraints typical of athletic programs. Athletes were asked to consume four green smoothies per week offered by the Fueling Station. The primary outcome was dermal carotenoid status assessed using the Veggie Meter®, a validated non-invasive biomarker of F&V intake. Fueling Station records assessed uptake and dose of the implemented strategy; body composition, blood pressure, and heart rate were measured as covariates. Changes in carotenoid status over 12 weeks were analyzed with repeated-measures ANOVA and linear mixed-effects models adjusting for sex and body composition. Associations and between-group differences were examined; pair-wise deletion was used.

Results: Complete data were available for 28 of the 60 final participants (53.9%). Mean Veggie Meter® scores rose significantly over time (baseline, midpoint, and post-intervention), with an average overall increase of 28% ($p < .05$). Greater uptake (e.g., more frequent smoothie consumption per week) predicted larger increases in dermal carotenoid status.

Conclusion: Provision of green smoothies through an on-site Fueling Station increases access to high carotenoid foods and increases overall dermal carotenoid status in Division 1 NCAA athletes. Fueling Stations represent a feasible, scalable platform for nutrition strategies that improve diet quality and support health, performance, and recovery when foods are provided in a palatable and easily consumable form. Improving access to convenient, enjoyable F&V-based options may support dietary behavior change and can be readily scaled by other athletic or institutional settings that support on-site food-provision.

I-P-E.22

A Transmural Allied Healthcare Pathway (TULIP): A Multi-methods Process Evaluation

J. van Grootel^{1,2}, S. Wiertsema^{1,2}, H. van Dongen^{3,4}, F. van Nassau⁵, E. Geleijn¹, R. Collet^{1,3,2}, M. van Bommel¹, R. Ostelo^{3,4}, M. van der Schaaf^{1,2,6}, M. van der Leeden^{1,2}

¹Amsterdam UMC, Rehabilitation Medicine, Amsterdam, Netherlands, ²Amsterdam Movement Sciences, Ageing and Vitality, Amsterdam, Netherlands, ³Vrije Universiteit, Health Sciences, Amsterdam, Netherlands, ⁴Amsterdam Movement Sciences, Musculoskeletal Health, Amsterdam, Netherlands, ⁵Amsterdam UMC, Public and Occupational Health, Amsterdam, Netherlands, ⁶University of Applied Sciences Amsterdam, Faculty of Health, Amsterdam, Netherlands

Purpose: This study aimed to evaluate the implementation, sustainability, and scalability of the TransmUral Allied healthcare Pathway (TULIP), a six-step transmural care pathway designed to improve collaboration and coordination across hospital, geriatric rehabilitation, and primary care to support recovery, physical functioning, and health behaviors in patients with complex needs after hospital discharge. Given that patients frequently require additional support in relation to nutrition and physical activity following hospitalization, these aspects are embedded within the pathway to facilitate recovery. This study applies a theory-informed, multi-methods process evaluation to a transmural allied healthcare pathway delivered in routine practice, explicitly focusing on real-world implementation and scalability rather than effectiveness alone.

Methods: We conducted a multi-methods process evaluation guided by the RE-AIM framework (Reach, Effectiveness, Adoption, Implementation, Maintenance). Data were collected from allied healthcare professionals, patients, and managers through interviews, focus groups, surveys, and electronic health records. Quantitative outcomes were descriptively and inferentially analyzed, while qualitative data were thematically analyzed. Findings were integrated using triangulation and reflexive team discussions to identify implementation barriers, facilitators, and conditions for scale-up.

Results: Reach indicated that allied healthcare professionals from hospital, geriatric rehabilitation and primary care were willing to participate in the project. Effectiveness analyses showed no significant improvements in perceived collaboration or work performance after implementation. Adoption varied across professionals and settings and was strongly dependent on the implementation researcher in this study while organizational ownership remained limited. Implementation was challenged by the complexity of the intervention and the involvement of multiple allied healthcare professionals from different settings. Maintenance and scalability appeared unlikely under current conditions: without structural embedding in policies, dedicated resources, and integration into routine workflows, engagement declined once external support decreased.

E. IMPLEMENTATION AND SCALABILITY

Conclusion: Implementation of transitional care interventions is feasible when supported by strong organizational commitment, alignment between care settings, and shared ownership among professionals. However, maintenance of TULIP was unlikely under the observed conditions, underscoring the need for structural organizational support, integration into routine workflows, and a clearly perceived need among professionals to achieve sustainable embedding within health systems.

I-P-E.23

Implementation of a Physical Activity Program for Community-dwelling Middle-aged and Older Women in Northeastern Brazil: Evaluation of Effectiveness

M.F.R. Santos¹, I.C. Santos¹, A.S. Bomfim¹, L.G.C. Mendes¹, A.A. Rocha¹, I.P. Novais¹, Research Group in Health, Physiology and Physical Activity (GPSFA)

¹State University of Southwestern Bahia (UESB), Health Department, Jequié, Brazil

Purpose: Middle-aged and older women are at increased risk of cardiovascular and metabolic diseases and represent the group with the highest prevalence of physical inactivity in Brazil. Community-based physical activity programs are promising strategies to promote health equity and improve physical, mental, and social well-being in this population. This study aimed to evaluate the effectiveness of implementing a physical activity program for community-dwelling middle-aged and older women in northeastern Brazil based on participants' perceptions.

Methods: This exploratory qualitative study was conducted with participants enrolled in a university-supported community-based project in northeastern Brazil. The program offered two supervised exercise modalities (multicomponent training and mat Pilates) delivered twice weekly over 12 weeks to women aged 50-69yrs, using university infrastructure and low-cost resources. Program effectiveness was assessed through focus groups guided by two effectiveness-related dimensions of the RE-AIM framework: (1) unintended negative consequences (i.e., unanticipated outcomes potentially resulting in harm) and (2) qualitative effectiveness indicators, capturing participants' perceptions regarding the extent to which the program achieved its intended benefits. Discussions were audio-recorded, transcribed verbatim, and analyzed using thematic content analysis supported by IRAMUTEQ software.

Results: Thirty-five women (59.6±4.4yrs; 27.7±3.9 kg/m²) participated and were organized into five focus groups. Participants reported reductions in pain and improvements in mobility, sleep quality, and overall vitality. Enhanced social connectedness, positive effects on mood and self-esteem, and a strengthened sense of belonging were emphasized. "Pain" also emerged as an unintended outcome. While often associated with improvement, some participants described discomfort during exercises, incorrect movement execution, or inadequate practice spaces, reinforcing the importance of careful supervision and monitoring. The supportive and welcoming environment fostered by staff and peer relationships emerged as a central facilitator of engagement and adherence. Participants additionally expressed willingness to continue if maintained within the community setting.

Conclusion: The positive evaluation of the program's effectiveness for community-dwelling middle-aged and older women in northeastern Brazil, based on participants' perceptions, underscores its scalability potential within community and university-supported settings. These findings contribute to implementation evidence from a middle-income country context, supporting community-based physical activity initiatives as viable and transferable models for promoting healthy aging.

I-P-E.25

Fidelity and Acceptability of Pregnancy Home Visits in Municipal Practice: A Mixedmethods Evaluation within the Bloom Study

C.T. Bonnesen¹, M. Rasmussen¹, R.R. Carlsson¹, T.R. Ubbesen¹, L. Kierkegaard¹, M.P. Jensen¹

¹National Institute of Public Health, University of Southern Denmark, Copenhagen, Denmark

Purpose: This study explores how community health nurses (CHNs) implement and experience pregnancy home visits within the context of the Bloom Study, a cluster-randomized controlled trial aiming to promote healthy weight development in infants and toddlers in Denmark. By focusing on fidelity and acceptability, the study contributes new insights into the early-phase implementation of a home-based preventive initiative.

Methods: This study is innovative in its use of a convergent mixed-methods design to provide a comprehensive and

E. IMPLEMENTATION AND SCALABILITY

practice-oriented understanding of how CHNs deliver and perceive pregnancy home visits. This design is particularly relevant given that fidelity and acceptability are complex implementation constructs that cannot be adequately captured through a single method. An online survey will be administered to all participating CHNs ($n = 134$) in January/February 2026 to systematically assess fidelity and acceptability across a large and diverse sample. To add depth and illuminate mechanisms behind the questionnaire findings, four focus group discussions with CHNs from four municipalities were conducted between May and August 2025. Survey responses will be analyzed using descriptive statistics in SAS 9.4. Audiorecorded focus groups have been transcribed verbatim and will be examined using Braun and Clarke's reflexive thematic analysis. The quantitative and qualitative results will subsequently be integrated using a sidebyside joint display, enabling comparison of convergence, divergence, and complementarity.

Results: Preliminary qualitative findings point to four central areas shaping CHNs' experiences with the pregnancy home visits: (1) the visits provide access to aspects of family life that CHNs would otherwise not observe, (2) these early insights strengthen the quality and focus of later postnatal consultations, (3) structured dialogue tools help facilitate and guide communication with families, and (4) conducting perinatal depression screening can be difficult when a relationship with the family has not yet been established.

Conclusion: Early findings suggest that CHNs consider pregnancy home visits both feasible and meaningful. The visits appear to strengthen the foundation for postnatal care, although early-stage depression screening may require further support or adaptation. Ongoing integration of mixedmethods findings will clarify how the intervention can be refined to optimize implementation in municipal practice.

I-P-E.26

Implementing a Systems Approach for Physical Activity Promotion in a Japanese Local Government: Co-creation Using a Nine-step Framework and Evaluation Design

K. Kikuchi¹, Y. Oguma^{1,2}, A. Hirata², E. Kamiyama³, K. Honda³

¹Keio University, Graduate School of Health Management, Kanagawa, Japan, ²Keio University, Sports Medicine Research Center, Kanagawa, Japan, ³Kanuma City, Sports Promotion Division, Kanuma, Tochigi, Japan

Purpose: Physical inactivity is a major global public health challenge. The Global Action Plan on Physical Activity 2018–2030 (GAPPA) emphasizes that promoting physical activity contributes to multiple Sustainable Development Goals, and requires coordinated action across sectors such as urban planning, transport, education, and the environment (WHO, 2018). The Global Status Report on Physical Activity 2022 highlights the need to strengthen implementation and evaluation at national and local levels (WHO, 2022). However, strong sectoral administrative structures in Japanese local governments often constrain cross-sectoral promotion and integrated evaluation. This study aimed to implement a systems approach in a Japanese municipality (Kanuma City; population: approximately 90,000; area: 490.6 km²) and to explore a locally adapted implementation process and evaluation design integrating the GAPPA framework.

Methods: A participatory action research approach was adopted through collaboration between researchers and municipal officers. The nine-step process for developing system maps and a theory of change (Corr, 2023) was referenced and reorganized to align with the municipal policy process in Japan. For the evaluation framework, perspectives from the Global Status Report 2022 were aligned with a Japanese logic model for physical activity promotion (Inoue, 2024), and a framework linking outputs, outcomes, and impacts was developed.

Results: The nine-step process required contextual adaptation. Policy analysis and problem definition were integrated, and an additional stage, “understanding the system,” was introduced to emphasize stakeholder dialogue. Plans and measures related to physical activity were reviewed across departments, and cross-sectoral workshops were conducted to visualize initiatives and relationships. Although relevant measures existed in multiple departments, they had not been recognized as a unified system. Workshops clarified overlaps and interconnections, highlighting mutual benefits across sectors. Perspectives shifted from viewing physical activity as a single-department responsibility to recognizing it as a cross-sectoral municipal priority. Evaluation discussions revealed a focus on outputs, with limited attention to outcomes. Integrating GAPPA perspectives with the Japanese logic model clarified pathways from outputs to outcomes and impacts.

Conclusion: Implementing a systems approach in Japanese local government requires contextual adaptation and sustained dialogue. Strengthening system understanding and embedding evaluation perspectives from the planning stage may support strategic and continuous physical activity promotion.

E. IMPLEMENTATION AND SCALABILITY

I-P-E.27

Bridging Policy and Practice: Stakeholder Insights on Early Childhood Obesity Prevention in Primary Healthcare Services

K. Kuswara¹, E. Rosewarne², J. Appleton^{3,1}, S. Taki^{4,1}, L.M. Wen^{4,1}, E. Denney-Wilson^{5,1}, L. Baur^{6,1}

¹NHMRC Centre of Research Excellence in Translating Early Prevention of Obesity in Childhood (CRE EPOCH-Translate), Sydney NSW, Australia, ²School of Health Sciences, Faculty of Medicine and Health, University of New South Wales, Sydney NSW, Australia, ³School of Nursing and Midwifery, Faculty of Health, University of Technology Sydney, Broadway NSW, Australia, ⁴Health Promotion Unit, Population Health Research and Evaluation hub, Sydney Local Health District, Sydney NSW, Australia, ⁵Faculty of Medicine and Health, Susan Wakil School of Nursing and Midwifery, The University of Sydney, Sydney NSW, Australia, ⁶Children's Hospital Westmead Clinical School, Sydney Medical School, The University of Sydney, Sydney NSW, Australia

Purpose: Australian primary healthcare services, including maternal child and family health (MCaFH) and general practice (GP), have near-universal contact with families in early life, presenting significant opportunities for population-level early childhood obesity prevention. Despite this reach, evidence-based practices are not delivered consistently. Using a systems perspective, this study examined MCaFH and GP services to identify drivers of this implementation gap and opportunities to strengthen early childhood obesity prevention at scale.

Methods: A qualitative study was conducted using semi-structured interviews with GPs, Practice Nurses, MCaFH practitioners, service managers, and their policy leads. Participants were recruited through professional networks and purposively sampled to capture diverse perspectives, with additional informants identified via snowball sampling. Interviews (Dec 2024–Sept 2025) were conducted via Microsoft Teams and analysed using reflexive thematic analysis approach.

Results: Thirty-three participants were interviewed (MCaFH n=17; GP n=15; national non-profit prevention agency n=1) across clinical, managerial, and policy roles. Three interrelated themes were identified. First, prevention opportunities vary according to service and funding design. MCaFH is structured to deliver scheduled preventive care, while GP operates under time-limited, fee-for-service models that prioritise acute care, making prevention opportunistic and inconsistent. Second, system fragmentation undermines continuity of care and prevention delivery. Services operate in siloes, referral pathways for at risk children are limited, and messaging on healthy growth, nutrition and physical activity is inconsistent. Third, workforce shortages and high turnover limit prevention capacity by diminishing expertise and relationships needed to engage families on sensitive issues such as obesity. Despite these challenges, participants highlighted opportunities to scale prevention through a skilled primary healthcare workforce and existing evidence-based early childhood obesity prevention initiatives.

Conclusion: This study identified opportunities to strengthen early childhood obesity prevention within routine primary healthcare in Australia. Early childhood obesity prevention is often deprioritised in resource-constrained health systems. Addressing the implementation gap requires structural reform that embeds prevention within funding and service models, improved coordination across services, and consistent messaging on healthy growth, nutrition and physical activity. Scaling evidence-based interventions and strengthening workforce capability with practical, strength-based tools, are essential to improve consistency and impact.

II-P-E.01

Associations between Organizational Practices and Policies and Individual Behaviors in a Faith-based National Implementation Study in the United States

S. Wilcox^{1,2}, A.T. Kaczynski^{1,3}, R.P. Saunders¹, A.C. Rudisill^{1,3}

¹University of South Carolina, Prevention Research Center, Columbia, United States, ²University of South Carolina, Department of Exercise Science, Columbia, United States, ³University of South Carolina, Department of Health Promotion, Education, and Behavior, Columbia, United States

Purpose: Interventions that change organizational practices and policies can reach large numbers of people and have the potential for substantial public health impact. Churches are an understudied but important community setting for reaching populations at elevated disease risk. In our national implementation study of a U.S. faith-based intervention, we documented favorable organizational- and individual/member-level changes. The purpose of the present study was to examine whether church practices and policies were associated with changes in member health behaviors.

E. IMPLEMENTATION AND SCALABILITY

Methods: This initiative focused on organizational-level outcomes as the primary outcome in 107 churches; however, we also examined member outcomes in a planned subsample. Members (N=511, 57.4±14.4 years, 76% women, 98% African American) from 17 churches completed online surveys before (baseline) and 12-mo after (n=351, 69% retained) their churches were trained online to implement an intervention focused on increasing organizational practices and policies for healthy eating (HE) and physical activity (PA). Members reported their perceptions of the frequency with which they observed these organizational practices (i.e., opportunities, messages, and pastor support) and the presence of policies in their church. They also reported their consumption of fruits and vegetables (cups/day) and engagement in PA (minutes/week). Mixed linear models that accounted for church clustering tested whether organizational practices/policies (baseline and 12-mo) were associated with changes in each of the member-level health behaviors; separate models were conducted for each organizational practice/policy. We report associations with a p-value<.10.

Results: Increased fruit consumption was positively related to baseline messages (p<.0001), 12-mo opportunities (p<.01), baseline pastor support (p<.05), and both baseline (p<.01) and 12-mo policies (p<.05). Increased vegetable consumption was positively related to 12-mo messages (p=.05), 12-mo opportunities (p=.07), and baseline pastor support (p<.05). Increased PA was positively related to baseline messages (p<.001), baseline opportunities (p<.01), baseline pastor support (p<.0001), and 12M policies (p=.07).

Conclusion: We found that church organizational practices and policies were associated with favorable changes in members' HE and PA behaviors. Intervention targets designed to create a healthier church environment, including sharing messages; increasing opportunities before, during, or after church events; enlisting pastor support; and setting policies, appeared important in influencing HE and PA behaviors among church members.

II-P-E.02

Barriers and Facilitators to the Implementation of Sit-Less and Move-More (SLAMM) Interventions within Australian Primary Healthcare Settings

A. Beecroft¹, D. Dunstan¹, S. Sahlqvist¹, D. Mohotti², A. Chapman²

¹Deakin University, Institute for Physical Activity and Nutrition, Melbourne, Australia, ²Deakin University, Institute of Health Transformation, Melbourne, Australia

Purpose: The primary healthcare setting presents a pragmatic setting for embedding interventions that target sitting less and moving more. To identify effective implementation strategies for such interventions, it is necessary to first understand the determinants that drive implementation. We examined the barriers and facilitators influencing the implementation of sit-less and move-more interventions within Australian primary healthcare settings, as perceived by General Practitioners and General Practice Nurses.

Methods: A qualitative descriptive study using individual semi-structured interviews was conducted. Ten General Practitioners and ten General Practice Nurses took part in online individual interviews. Interviews were digitally transcribed and analysed deductively; both the interview guide and analysis were guided by the Theoretical Domains Framework.

Results: All 14 domains within the Theoretical Domains Framework were represented. Predominant barrier domains were Environmental Context and Resources (Domain 11), related to reported time constraints, Skills (Domain 2), relating to a lack of formal training, and Social Influences (Domain 12), reflecting patients' own motivation and resistance to behaviour change. Predominant facilitator domains were Social/Professional Role and Identity (Domain 3), highlighting that both General Practitioners and General Practice Nurses can have a role in implementing sit-less and move-more interventions within primary healthcare, Beliefs about Consequences (Domain 6), relating to the health benefits that exist for patients with healthier movement behaviours, and Environmental Context and Resources (Domain 11), relating to the use of educational resources and the integration of sit-less and move-more assessments within clinic workflow.

Conclusion: Strategies supporting the successful implementation of sit-less and move-more interventions within primary healthcare need to take into consideration: the time constraints; competing priorities; and the lack of training that exists for clinicians. The development of practical resources, including posters and patient handouts, and the integration of an efficient screening tool within practice workflows, may help to facilitate implementation. These findings provide a foundation for future research focusing on the co-design of strategies that could support the implementation of such interventions within primary healthcare.

E. IMPLEMENTATION AND SCALABILITY

II-P-E.03

Scaling up a Community-led Food Access Program: Exploring Barriers and Facilitators in a Rural Setting Using the Consolidated Framework for Implementation Research (CFIR)

T. Petresin¹, R. Girma¹, N. Shujaiddin², A. Annis¹, D. Ma¹, A. Domingo¹, J. Haines¹, f. Community Advisors²

¹University of Guelph, Guelph, Canada, ²10C Shared Space, Guelph, Canada

Purpose: Food insecurity remains a significant and persistent public health issue across Canada. This study examined barriers and facilitators to implementing food uniting neighbours (f.u.n.), a co-designed, community-based food access program originally developed for an urban setting, in a new rural context.

Methods: A qualitative study using the Consolidated Framework for Implementation Research (CFIR) was conducted in Centre Wellington, a rural township in Southwestern Ontario, Canada, to understand the barriers and facilitators of implementing the f.u.n. program in a rural context. Fourteen food access programming staff and community champions participated in semi-structured interviews and six community members with lived experience accessing food programs participated in a focus group. Data were analyzed using template analysis to identify barriers and facilitators to program implementation across CFIR's five domains: Innovation, Outer Setting, Inner Setting, Individuals, and Implementation Process.

Results: Barriers to implementing f.u.n. within this rural context included transportation challenges, funding instability, stigma, and fragmented service coordination, issues amplified by the rural context and lack of anonymity. Facilitators included strong community readiness for change, inclusive engagement of individuals with lived experience, and opportunities for advocacy and leadership. Participants emphasized the need for holistic, flexible, and community-driven interventions that address food insecurity alongside other unmet needs.

Conclusion: This study identified key factors and strategies for adapting and scaling up f.u.n. within a rural context, emphasizing inclusive engagement, leadership, and solutions to rural challenges such as transportation, funding, stigma, and equitable participation. Results provide practical guidance for scaling and sustaining co-designed food access interventions in rural settings, helping bridge the gap between research and real-world impact.

II-P-E.04

Promoting Physical Activity among Mothers and Pre-adolescent Daughters: Adapting an Online Program to an In-person Format

E. Arredondo¹, J. Schneider², D. Chagolla², T. Baranowski³, K. Butte⁴, L. Brookman-Frazee⁵, S. Roesch¹, T. O'Connor⁶, E. Gomez⁷, M. Torres-Ruiz⁸, J. Sedeno⁹, N. Ayala², G.X Ayala¹⁰

¹San Diego State University, Department of Psychology, San Diego, United States, ²San Diego State University, Institute for Behavioral and Community Health, San Diego, United States, ³Baylor University, USDA/ARS Children's Nutrition Research Center, Department of Pediatrics, Houston, United States, ⁴Seattle Pacific University, Department of Health and Human Performance, Seattle, United States, ⁵University of California, San Diego, Department of Psychiatry, San Diego, United States, ⁶Baylor College of Medicine, Section of Pediatric Cardiology, Department of Pediatrics, Houston, United States, ⁷San Diego State University and University of California, San Diego, SDSU-UCSD Joint Doctoral Program in Public Health, San Diego, United States, ⁸San Diego State University, Institute for Behavioral and Community Health, San Diego State University, United States, ⁹YMCA, YMCA of San Diego, San Diego, United States, ¹⁰San Diego State University, School of Public Health, San Diego State University, United States

Purpose: Few studies have reported on the adaptation of behavioral interventions from one delivery format to another. Conmigo - Physical Activity is a culturally tailored intervention that promotes physical activity among Latina mothers and their pre-adolescent daughters. This presentation describes the systematic adaptation of the online Conmigo-Physical Activity program—originally delivered by the research team—to an in-person format implemented in elementary schools by YMCA staff.

Methods: Conmigo sessions promote physical activity by targeting parenting strategies, family communication, and mutual support between mothers and daughters. The online Conmigo-Physical Activity program was a randomized controlled trial consisting of twelve 1.5-hour weekly sessions delivered by the research team. The in-person version, implemented through partnerships with schools and YMCAs, employs a Hybrid Type 1—implementation design. It includes ten 2-hour weekly sessions co-led by trained YMCA staff. The adaptation process was informed by iterative input from the scientific team and a Community Advisory Board to ensure cultural and contextual relevance.

E. IMPLEMENTATION AND SCALABILITY

Adaptations were documented systematically using established implementation science methods and focused on modifying session length, delivery format, and examples to align with community partner resources, participant schedules, and local priorities.

Results: Adaptations included adding fitness assessments and structured YMCA staff training to strengthen program fidelity. Implementation in community settings was feasible, and alignment with school priorities supported coordination and recruitment. Participant engagement strategies differed by delivery format. In-person sessions leveraged social interaction, WhatsApp groups for peer support, and group accountability, along with hands-on activities, to promote participation. In contrast, the online format required more intentional strategies to foster connection and sustain motivation, such as incorporating interactive polls and brief movement breaks to maintain participant engagement.

Conclusion: Careful consideration is needed when translating a program from one delivery format to another, particularly regarding the types of activities implemented. Online and in-person formats each present distinct challenges and opportunities. These adaptations highlight the importance of tailoring facilitation techniques to the delivery modality to maintain participant interaction and program fidelity. Lessons learned from this adaptation process can guide future efforts to modify evidence-based interventions across diverse delivery formats to enhance reach, equity, and sustainability.

II-P-E.06

Implementer and Implementation Support Practitioner Needs for Sustaining Healthy Food Retail Practices in Australian Foodservice Settings: Findings from a National Survey

B. Backman¹, S. Naughton¹, V. Brown², S. Yoong¹, M.R Blake¹

¹Deakin University, Institute for Health Transformation, Global Centre for Preventive Health and Nutrition, Geelong, Australia, ²Deakin University, Institute for Health Transformation, Deakin Health Economics (DHE), Geelong, Australia

Purpose: Food outlet practices that support consumers in making healthier food and drink purchases (e.g. healthy product availability and promotion) are key strategies for improving population diets. To have lasting population health impacts, these practices must be sustained; however, evidence on their long-term maintenance in real-world settings is limited. This study explored implementer (e.g. retailers, managers, outlet staff) and practitioner (e.g. health promotion officers, dietitians) perspectives on (i) which healthy food retail practices are typically sustained or discontinued in foodservice context, (ii) key determinants influencing sustainment, and (iii) support needs for sustaining change.

Methods: A national cross-sectional online survey was conducted with implementers and implementation support practitioners. The survey was co-designed with representatives from all Australian state and territory governments. Recruitment targeted government-priority settings (e.g. healthcare food retail, school canteens) and private outlets using Qualtrics panels, professional networks, and social media. Survey items covered outlet characteristics, sustained and discontinued practices, barriers and enablers to sustainment (categorical and ranking), and support needs, informed by previous evidence and the Expert Recommendations for Implementing Change glossary. Data were analysed descriptively, with ranking analyses used to identify priority determinants.

Results: A total of 294 eligible participants completed the survey (222 implementers, 72 practitioners) from all Australian jurisdictions, most commonly Victoria (31%) and New South Wales (22%). Overall, 53% reported at least some healthy food retail practices being sustained over time, and 45% reported discontinued practices. Increasing the range of healthier options was the most frequently sustained practice (n=85), while reducing less healthy products was most often discontinued (n=59). Commonly ranked top enablers were access to healthy food suppliers (33% participants ranking in their top three) and staff motivation (28%), while key barriers were additional costs (23%) and limited supplier access (22%). Subgroup analyses are underway and will be presented.

Conclusion: This is the first national survey to explore implementer and practitioner perspectives on sustaining healthy food retail practices across foodservice settings. Findings highlight the influence of financial and supplier-related factors. Addressing these determinants when designing sustainment supports may help enable long-term transformation of food retail environments and, in turn, support healthier consumer purchasing behaviours.

E. IMPLEMENTATION AND SCALABILITY

II-P-E.07

Reimagining School Meals in Australia: Implementing Australia's First Government Funded Cooked School Lunch Program

K. Jose¹, K. Smith¹, M. Reardon², K. De Paoli², C. Galloway², J. Dunbabin³, N. Masila¹, L. Sutton¹, B. Fraser¹, F. Proudfoot¹, V. Cleland¹

¹University of Tasmania, Menzies Institute for Medical Research, Hobart, Australia, ²Department of Health, Public Health Services, Hobart, Australia, ³School Food Matters, Hobart, Australia

Purpose: Australia's first government funded cooked school meal program was implemented in 30 schools in the state of Tasmania in 2022-2023. Led by non-government organisation School Food Matters in partnership with food security organisation Loaves and Fishes Tasmania and the Tasmanian Departments of Premier and Cabinet and Health the project was a catalyst for reimagining the provision of school meals in Australia. In 2023, 191,968 cooked school lunches were provided to 4,104 students in 30 schools. This evaluation aimed to capture implementation strategies, successes and challenges for this innovative project.

Methods: A developmental evaluation approach was adopted as it supports social innovation and systems change. The evaluation team (N = 7): worked closely with the project implementation team to develop the project logic and evaluation protocol, attended weekly/fortnightly operational project meetings, participated in the project advisory committee, established an evaluation working group, and co-facilitated reflective workshops with implementation team members in 2022 and 2023. Using a qualitative approach, data collection included project and workshop documents, meeting minutes, and interviews with the implementation team and school staff. Data was collated and analysed thematically.

Results: In 2022-2023, 81 school staff and implementation team members were interviewed and two workshops held. Themes representing successful implementation were: A common purpose and shared goal („to feed all children well at school“); Partnerships and collaboration; Flexibility; and Redirection of resources. Themes representing initial challenges were: ‘Thrown in the deep end’ (“There was a lot of anxiety”); Insufficient resourcing; School staff capacity; and Goodwill. The project attracted interest from local and national politicians, media and school food organisations. School and project implementation staff expressed pride at successfully providing children cooked lunches and in late 2023 were focused on expansion and sustainability of the project.

Conclusion: This paradigm shift in food provision in Australian schools generated intense interest and created unanticipated demands on individuals and organisations delivering the program. Successful implementation in the first two years relied on a commitment to the project's shared vision and substantial personal and organisational in-kind support. Transforming school food systems requires multisectoral collaboration and a willingness to challenge the status quo.

II-P-E.08

Preliminary Findings for the Development of a Care Pathway for Individuals with Recent Gestational Diabetes Mellitus: A Qualitative Study

S. Cretton^{1,2}, J. Maltais-Proulx¹, A.-S. Morisset^{2,3}, P. Lemieux^{3,4}, A. LeBlanc^{5,6}, M. Turcotte¹, C. Simoneau¹, J.S. Weisnagel³, M.-E. Piché⁷, É. Carbonneau^{1,2}, S. Desroches^{1,2}, J. Robitaille^{1,2,8}

¹Centre Nutrition, Santé et Société (NUTRISS), Institut sur la Nutrition et les Aliments Fonctionnels (INAF), Université Laval, Québec, Canada, ²École de Nutrition, Université Laval, Québec, Canada, ³Axe Endocrinologie et Néphrologie, Centre de Recherche du CHU de Québec – Université Laval, Québec, Canada, ⁴Département de Médecine, CHU Québec – Université Laval, Québec, Canada, ⁵Chaire de Recherche du Canada en Mobilisation et Intégration des Connaissances en Pratique, VITAM – Centre de Recherche en Santé Durable, Québec, Canada, ⁶Département de Médecine de Famille et de Médecine d'Urgence - Université Laval, Québec, Canada, ⁷Institut Universitaire de Cardiologie et de Pneumologie de Québec – Université Laval, Québec, Canada, ⁸Axe Endocrinologie et Néphrologie, Centre de recherche du CHU de Québec – Université Laval, Québec, Canada

Purpose: Individuals with a history of gestational diabetes mellitus (GDM) are at high risk of developing type 2 diabetes (T2D) and cardiovascular diseases (CVDs) later in life. Currently, no systematic postpartum follow-up is offered for individuals who have had GDM despite the evidence that T2D and CVDs can be prevented through adequate screening and lifestyle modifications. The overall objective of this study is to develop a care pathway to provide better postnatal care to individuals with a history of GDM (patients) within the healthcare system by mobilizing existing knowledge and

E. IMPLEMENTATION AND SCALABILITY

resources on T2D and CVDs prevention. Specifically, this project aims to 1) identify the needs, facilitators and barriers to the development of the care pathway and 2) co-develop the care pathway and evaluation plan with patients and healthcare providers (HCPs).

Methods: Firstly, based on the Normalization Process Theory, 24 to 30 semi-structured individual interviews (n=12-15 patients and n=12-15 HCPs) will be conducted virtually. The most salient and relevant elements from all interviews will be considered along the best practices identified in the scientific literature to develop a relevant care pathway. Secondly, outcomes for implementation research defined by Proctor et al. (feasibility, acceptability and adoption) and RE-AIM (Reach, Effectiveness, Adoption, Implementation, Maintenance) will be included in an evaluation plan. Eight to 16 additional interviews (n=4-8 patients and n=4-8 HCPs) will be conducted to refine the care pathway and evaluation plan.

Results: Interviews have already been conducted with patients who have had GDM during their latest pregnancy (n=7). Preliminary findings suggest a lack of guidance and information post-delivery, with many participants unaware of long-term health risks and preventive recommendations, relying instead on personal research. Participants expressed a need for structured, personalized follow-up soon after delivery and clear lifestyle guidance to overcome barriers such as limited time and motivation.

Conclusion: This study will provide an opportunity to develop inclusive and effective care based on users' needs and scientific evidence. Results would be scaled up to other administrative regions of the province of Quebec (Canada) to improve the care of people with prior GDM to prevent T2D and CVDs.

II-P-E.09

Examining the Role of Community-based Organizations in the Equitable Implementation of Seattle's Fresh Bucks Produce Voucher Program Using REAIM and Food Access Domains Frameworks

B. Baquero¹, K. Hara-Hubbard¹, M. Flores Moreno², E. Grijalva Martinez¹, J. Wallace¹, P. Chaparro³, M. Knox⁴, J. Jones-Smith¹

¹University of Washington, Health Systems and Population Health, Seattle, United States, ²University of Washington, Epidemiology, Seattle, United States, ³University of Washington, Food Systems, Nutrition, and Health, Seattle, United States, ⁴University of Washington, Economics, Seattle, United States

Purpose: The City of Seattle's Fresh Bucks produce voucher program is effective in increasing consumption of fruits and vegetables and food security among its participants. We examine the role of community-based organizations (CBOs) in the equitable implementation of this program.

Methods: Using qualitative methods, we ascertained the experience of 12 CBOs implementing the Fresh Bucks program. We applied the REAIM and Nutrition Food Access Domains frameworks to analyze the data, using deductive coding and thematic analysis. Then, we co-interpreted and integrated the findings with the CBOs.

Results: Thirty-four individuals participated in focus groups. CBOs reached low-income communities of color (e.g., African/African American, Asian/Asian American, Pacific Islander, Latino, Middle Eastern), immigrants and refugees, and older adults. CBOs were located across the city and offered diverse programming, including social services, support groups, food and health programs, and civic engagement. CBOs agreed to adopt Fresh Bucks because they wanted their clients to benefit from it, and it aligned with their mission. Engaging in program implementation increased the CBOs' visibility and trust in community, building organizational capacity. CBOs reported their clients experience improved physical, social, and emotional health, as well as increased personal development in learning and applying their nutrition knowledge to their lives. CBOs increased enrollment by providing accessible locations and using customers' primary language. CBOs increased the usability of the program by providing technical assistance on store locations, card use, troubleshooting errors, and advocating for more culturally relevant and convenient stores. CBOs provided one-on-one support to increase Fresh Bucks usage where technological literacy and language barriers emerged. CBOs mentioned that their reputation and trust with the community were strengthened by participating in Fresh Bucks, thus, all CBOs wanted to continue working with Fresh Bucks. They continued to provide customer feedback to the City to increase the usability of Fresh Bucks for their customers.

Conclusion: CBOs serve a crucial role in equitably implementing Fresh Bucks by increasing accessibility and bridging the city's programming with the program's customers. Local government and organizations seeking to implement healthy food voucher programs should include trusted CBOs to support the equitable implementation and effectiveness of their programs.

E. IMPLEMENTATION AND SCALABILITY

II-P-E.10

Mechanisms and Contextual Factors for Sustainably Implementing the Dutch Healthy School Canteen Program: A Realist Evaluation Perspective

B. van Dongen¹, C. Renders¹

¹Vrije Universiteit Amsterdam, Health Sciences, Amsterdam, Netherlands

Purpose: To promote healthy dietary behaviors among adolescents, the Dutch Healthy School Canteen(HSC)-program aims to make healthier options more easily available, accessible and attractive in secondary schools without restricting students' food choices. Although the program has potential, structural and sustainable implementation remains challenging for schools. This study explores the contextual factors and underlying mechanisms that influence successful and sustainable implementation of the program.

Methods: A qualitative study using interviews and focus-groups was conducted, following 'realist evaluation'-principles to examine barriers and facilitators for sustainable implementation. Data were collected among implementing stakeholders of the HSC-program (interviews, n=28), students (interviews, n=3; focus-groups, n=21) and professionals that support implementation on a national level (focus-groups, n=6). An expert meeting was conducted with specialists in implementation and school food environments to reflect on initial observations (focus-group, n=25). Using a retroductive approach, configurations of contextual factors (C) and underlying mechanisms (M) were identified that led to certain outcomes (O) based on an initial program theory explaining how the HSC-program works.

Results: CMO-configurations around five outcomes were developed: 1) developing a tailored action-plan, 2) sustaining effective leadership roles, 3) continuously involving adolescents, 4) adhering to program guidelines, and 5) maintaining sustained commitment. Some examples were: to achieve outcome 1, action-plans need to be developed with all relevant stakeholders (M), through regular meetings in which transparency and a safe environment for different perspectives are fostered (C). To achieve outcome 2, leaders need to experience trust and autonomy (M), which can be achieved when official school-leaders balance providing freedom and showing involvement (C). To achieve outcome 4, implementing staff need to understand the guidelines and know where deviation is possible (M), which was fostered by guidance of professionals around schools (C).

Conclusion: This study highlights the importance of broadly supported school-policy that includes a clear vision and well-defined roles and responsibilities, while also maintaining flexibility to adjust to changing circumstances. Such an approach not only supports developing action plans; it also fosters other outcomes, such as leadership and adherence of program principles. Ongoing expert guidance to schools to find this balance is essential to achieve sustainable implementation.

II-P-E.11

Adaptive Implementation Strategies for Nutrition Education in Early Care and Education: Preliminary Results from the OptiWISE Trial

T. Massey-Swindle^{1,2}, D. Zhang³, S. Johnson⁴, J. Selig³, J. Painter³, G. Curran³, J. Rutledge⁵

¹University of Arkansas for Medical Sciences, Pediatrics, Little Rock, United States, ²Arkansas Children's Research Institute, Little Rock, United States, ³University of Arkansas for Medical Sciences, Little Rock, United States, ⁴University of Colorado Anschutz, Aurora, United States, ⁵Louisiana Tech University, Ruston, United States

Purpose: Early Care and Education (ECE) settings provide critical opportunities to establish healthy eating habits, yet many centers do not implement evidence-based practices (EBPs) for nutrition education. *Together, We Inspire Smart Eating* (WISE) promotes four EBPs to increase children's intake of carotenoid-rich fruits and vegetables through hands-on learning, educator modeling, and supportive classroom environments. To address variable implementation across settings, we tested an adaptive implementation strategy designed to intensify support only for sites that did not initially respond to low-intensity strategies.

Methods: We used an enhanced non-responder trial design across ECE centers (N=67) implementing WISE. Following an initial implementation period, non-responder sites were randomized to either (a) continue receiving low-intensity support or (b) receive high-intensity support. Sites were classified into six response categories reflecting fidelity patterns over time: (1) maintained early response (responded initially and sustained), (2) regressed (responded initially but did not sustain), (3) late response–low intensity (responded after continued low-intensity support), (4) non-response–low intensity (did not respond despite continued low-intensity), (5) late response–high intensity

E. IMPLEMENTATION AND SCALABILITY

(responded after receiving high-intensity support), and (6) non-response–high intensity (did not respond despite high-intensity support). We examined distributions across categories to characterize response trajectories and assess the added value of intensified support.

Results: Among early responder sites to low-intensity strategies (n=10), 70.0% maintained their early response, while 30.0% regressed. Of sites randomized to continued low-intensity support (n=34), 88% remained non-responders and 12% became late responders. Among sites randomized to high-intensity support (n=23), 43.5% achieved late response and 56.5% remained non-responders. Early responders generally sustained engagement, most low-intensity sites remained nonresponsive, and nearly half of high-intensity sites demonstrated late improvements by year's end.

Conclusion: High-intensity implementation support produced a threefold higher rate of late response compared with continued low-intensity support, highlighting the potential value of adaptive implementation approaches for initially non-responsive sites. Ongoing mixed-methods analyses will identify mechanisms driving response to inform efficient, scalable models that enhance nutrition EBP uptake and sustainability in ECE settings.

II-P-E.12

The 50K4Life Study Community Advisory Board: Bridging Community with Research to Improve Walking Engagement in El Paso, Texas Public School Teachers

J. Salinas¹, D. Parra-Medina²

¹University of Texas at El Paso, Social Work, El Paso, United States, ²University of Colorado, Denver, United States

Purpose: Community participation enhances prevention research. This paper provides an overview of the development of a community advisory board (CAB) to inform the 50K4Life study, a walking intervention aimed at public school teachers participating in a clustered Sequential Multiple Assignment Randomized Trial (SMART) in El Paso, Texas.

Methods: We describe the formation of the CAB, the roles of its members, the research team, and examine how this collaborative process contributed to continued engagement. Grounded in community-based participatory research (CBPR) framework, membership was based on word of mouth and identification of key stakeholders in the community.

Results: CAB membership consisted of 27 Hispanic adults aged 30-60, who represented 7 different sectors. Structured monthly meetings, with an average attendance of 13 participants, served as a forum for CAB members to evaluate study materials for cultural relevance, while researchers provided resources consistent with member's expressed interests. Feedback was gathered during these meetings and through asynchronous contributions in shared documents. Over a 15-month period, CAB members participated in the refinement of three sets of study materials. Two members reviewed 196 English, 196 Spanish, and 196 hybrid dual-language messages with suggested revisions for verb tense and language formality. Six members reviewed a group intervention manual, and 16 members reviewed four educational modules, with recommendations for both that emphasized the importance of cultural appropriateness and inclusion of locally sourced imagery. As part of a larger effort to integrate mutuality into the CAB process, researchers shared 13 resources and invited three guest speakers.

Conclusion: The 50K4Life CAB process enhanced community representation, trust, and reciprocal engagement through the integration of study materials that are culturally appropriate for underrepresented populations in El Paso, Texas.

II-P-E.13

Canadian Registered Dietitians' Confidence, Facilitators, Barriers, and Resource Needs in Engaging Fathers: A Cross-sectional Exploratory Study

H. Lo¹, A. Chapleau², P. Morelli², J. Haines², G. Ball³, B. Lo²

¹University of California Davis, Department of Nutrition, Davis, United States, ²University of Guelph, Department of Family Relations and Applied Nutrition, Guelph, Canada, ³University of Alberta, Department of Pediatrics, Edmonton, Canada

Purpose: Despite fathers' crucial role in shaping children's diet and diet-related outcomes, they are underrepresented in pediatric nutrition interventions and services, partly due to the limited knowledge on how to engage fathers. Registered dietitians (RDs) are uniquely positioned to engage fathers in pediatric nutrition interventions and services. Our purpose was to explore Canadian RDs' perceived confidence, facilitators, barriers, and resource needs in father engagement.

E. IMPLEMENTATION AND SCALABILITY

Methods: In this cross-sectional study, participants were eligible if they provided direct pediatric nutrition care or services and were able to complete an online Qualtrics survey in English between November 2024 and July 2025. Participants reported their confidence in various aspects of father engagement using a five-point Likert scale (1=not confident at all to 5=very confident) and indicated resource needs to support father engagement from a list of provided options. Participants also provided qualitative written responses on perceived facilitators and barriers to father engagement. Quantitative data were analyzed descriptively using R; qualitative data were analyzed using inductive content analysis and summarized by frequencies representing the number of unique participants who mentioned each theme.

Results: From the 129 (97% female, 91% white) participants, many reported being either confident or very confident in recruiting fathers (85%), encouraging their participation (84%), involving them in strategy development for behaviour change (81%), supporting fathers' success in implementing diet-related strategies (78%) and sustaining behaviour changes over time (75%), as well as retaining fathers in ongoing pediatric nutrition care or services (67%). Only 3% had received prior training in father-engagement practices. The top three selected resource needs were webinars (90%), practice guidelines (65%), and hands-on workshops (32%). From written qualitative responses, common facilitators were fathers' availability (40%), interest in making positive changes (35%), high caregiving involvement (24%), and RDs' recognition of fathers as equal caregivers (17%). Reported barriers included fathers' absence from nutrition services (33%), limited caregiving roles (33%), rigid work schedules (23%), and traditional gendered caregiving norms (17%).

Conclusion: While RDs reported confidence in various aspects of father engagement, few had received formal training in this area. Opportunities exist to promote facilitators and mitigate barriers to father engagement through webinars, practice guidelines, and workshops.

The Health Promoting School Research Group Europe: Supporting Knowledge Exchange and Collaboration between Researchers

K. Bessems¹, J. Segrott²

¹Maastricht University, Health Promotion - NUTRIM Institute of Nutrition and Translational Research in Metabolism, Maastricht, Netherlands, ²Cardiff University, Centre for Trials Research, DECIPHer, Cardiff, United Kingdom

Purpose: The Health Promoting Schools Research Group Europe (HPS-RG) is a consortium of researchers and research institutions from the World Health Organization's (WHO) European Region. As the Schools for Health in Europe Research Group (SHE-RG) will cease its activities in late 2025, the HPS-RG will operate independently from 2026 onwards, continuing the work of the SHE-RG. The group's aim is to establish a knowledge exchange community that connects research silos and generates research that meets the needs of schools and their partners.

Methods: The HPS-RG is a group of scholars who are experts in, and interested in further developing, researching and evaluating, relevant issues and approaches to school health promotion. The group is committed to supporting the wider health-promoting schools ecosystem by collaborating with national Health Promoting School coordinators, the WHO, policymakers and other partners. Each year, the two co-chairs develop a working plan to guide the group's activities.

Results: Main activities working plan 2026

1. *Governance and membership.* The group is led by two co-chairs, who report to a steering group comprising HPS-RG delegates. The group is open for HPS researchers from a variety of backgrounds, such as career stage and gender. There is no participation fee.
2. *Online seminars.* Three to four online research seminars will be organised to showcase and disseminate current work from members.
3. *HPS Academy.* A HPS Academy is prepared to support young researchers in school health promotion in developing their careers and expanding their professional networks. Members will collaborate to determine the format and focus of the HPS Academy.
4. *Communication channels.* To improve communication, a website and/or online group will be launched on an existing platform, such as LinkedIn, to increase visibility and engagement.
5. *News.* Members will receive email updates at least three times a year, containing information about activities, events and alerts from research papers by members.

Conclusion: The HPS-RG provides a platform for knowledge exchange among researchers, ultimately supporting the implementation of whole-school approaches in the WHO European Region.

E. IMPLEMENTATION AND SCALABILITY

II-P-E.15

Understanding Local Adaptation of Nutrition and Agricultural Literacy Programs in the United States

C. Beattie¹, C. Vong¹, A. MacMillan Uribe¹, M. Graham¹, C. Rethorst¹, R. Seguin-Fowler², J. Szeszulski¹

¹Texas A&M Agrilife Research, Healthy Living, Dallas, United States, ²Texas A&M Agrilife Research, Healthy Living, College Station, United States

Purpose: Nutrition and agricultural literacy programs provide research-based education to youth about local food systems. Delivered by Cooperative Extension agents (i.e., community health educators affiliated with United States [US] land-grant universities), these programs aim to translate scientific knowledge into practical applications for diverse populations, fostering community learning and engagement. Extension agents play a critical role in planning and delivering nutrition and agricultural literacy programs, yet little is known about if/how they systematically and/or reactively adapt these programs for delivery.

Methods: Fourteen semi-structured interviews were conducted with Extension agents across Texas, US, to explore their experiences planning, delivering, and adapting nutrition and agricultural literacy programs. One researcher read each transcript, created a written summary, and interview summaries were analyzed using an inductive, thematic approach. Additionally, ChatGPT was used to conduct an independent AI-assisted qualitative analysis that analyzed summaries, generated inductive codes, and identified preliminary themes. The researcher and AI-generated codes and themes were then compared and discussed with the research team to finalize four themes.

Results: Theme 1: A structured but flexible process is used to plan agricultural literacy events. One interviewee reported, “We do yearly planning, but there’s definitely probably a three-to-six-month time frame [planning process] on those, too.” Theme 2: Relational networks and partnerships affect program feasibility and adaptation, influencing content choices (e.g., local commodities) and sometimes constraining program decisions. One interviewee reported, “With the dairy cow program... you’re looking a year out for an opportunity with them.” Theme 3: Informal evaluation and community feedback drive incremental changes. One interviewee reported, “The teachers asked for a longer event, so we’ll try to add more stations.” Theme 4: Program content and delivery are adapted to audience needs and age and emerging extension priorities. One interviewee reported, “You’ve got to structure it around 4th grade and 2nd grade minds, which is difficult to do.”

Conclusion: These findings highlight the complex interplay between the planning process, community relationships, feedback, and audience considerations in shaping nutrition and agricultural literacy programs. Understanding how Extension agents navigate these factors can inform strategies to support program adaptation, optimize resource use, and enhance educational impact across diverse communities.

II-P-E.16

Implementing a Food Prescription Program Into a Primary Care Clinic in an Urban Setting in Ontario, Canada

E. Zvereva¹, S. Kandasamy¹, R. de Souza¹, B. McKenna², M. Sergeant¹

¹McMaster University, Hamilton, Canada, ²Hamilton Family Health Team, Hamilton, Canada

Purpose: The purpose of this study is to identify barriers and facilitators to embedding a food prescription intervention in Hamilton, Ontario to support people living in food insecurity and with Type 2 Diabetes Mellitus. This study will respond to the following research question: What are the key barriers and facilitators to accessing healthy food for people living with food insecurity in Hamilton (Ontario, Canada)?

Methods: In this study we used an explanatory sequential design (Mixed Methods) with a community based participatory lens. This research design involves the preliminary collection of quantitative data which is followed by collection of qualitative data to deepen our understanding. To collect the quantitative data, we completed a dotmocracy ranking exercise. We then followed-up with focus group discussions to deepen the team’s understanding of the priorities identified during the dotmocracy exercise in alignment with Experience-Based Co-Design. Three groups involved are:

- 1) Clinicians,
- 2) Patients,
- 3) Community partners.

E. IMPLEMENTATION AND SCALABILITY

Results: The first quantitative ranking phase helped identify which questions needed to be further probed and discussed during the qualitative phase. Since the goal of the study was to involve individuals and community partners in the research process to ensure the findings are useful to the community, the qualitative data and their analysis helped to refine and explain the quantitative results by providing an in-depth view of the participants' perspectives. Once all data collection is complete, we will integrate the two sets of results and the qualitative results will help us explain the quantitative results.

Conclusion: The end-point of the study will be a list of priorities with importance rankings that are most relevant to the study population of

- 1) Clinicians,
- 2) Patients and
- 3) Community partners in Hamilton.

Building a holistic understanding of the barriers and facilitators encountered by community partners in accessing healthy food and achieving wellbeing may help improve healthcare delivery and community health outcomes.

II-P-E.17

Participant Satisfaction with Different Modes of Produce Prescription Program Delivery

L. McCormack¹, C. Hockett¹

¹Avera Research Institute, Sioux Falls, United States

Purpose: Incentivizing the purchase of fruits and vegetables through produce prescription programs can enhance produce affordability, improving both consumption of fruits and vegetables as well as clinical health indicators. Program delivery models can vary and include in-store vouchers and produce box delivery. The purpose of this study was to determine if participant satisfaction differed by program delivery mode among adults receiving \$25 per week in program incentives for six months.

Methods: Participants (n=206) were randomized to receive a weekly incentive for six months of either \$25 in paper vouchers to spend on fresh produce at a local grocery store or a box of pre-determined produce valued at \$25 delivered to their home. Program satisfaction data were collected via survey at the end of the six-month program intervention. Summary statistics were used to describe overall survey data and t-tests and chi-square tests were used to examine incentive group differences in continuous and categorical survey responses, respectively.

Results: Demographic characteristics did not differ between incentive groups. Participants were majority female (82%) with a mean age of 47 years (± 13.5 years). Program satisfaction was high among all participants. Over 83% of participants indicated being satisfied or very satisfied with program and satisfaction did not differ between incentive groups ($p=0.657$). Along with high overall program satisfaction, among participants receiving the produce delivery box, 64% reported being satisfied with the type of produce delivered and 72% reported being satisfied with the amount of produce provided. Among participants receiving in-store vouchers, 58% reported being satisfied with the process of redeeming the vouchers and 88% reported being satisfied with the dollar amount provided.

Conclusion: Although overall satisfaction is high among participants in this produce prescription program that uses paper vouchers and a produce delivery box, particularly regarding the amount of produce supplied through incentives, there is room to improve the participant experience. Future program adjustments could consider participant customization of the produce delivery box and electronic payment options versus vouchers and should examine the impact of these enhancements on dietary and health outcomes of participants.

II-P-E.18

The Generation Healthy Kids School Lunch Program: Facilitators and Barriers for Implementation

L. Lund¹, K.M. Kristensen², L.K. Ulrikkeholm², L.T. Thomsen³, U. Toft^{3,4}, C.T. Damsgaard², R.F. Krølner¹

¹National Institute of Public Health, University of Southern Denmark, Health Promotion and Interventions, Copenhagen, Denmark, ²University of Copenhagen, Department of Nutrition, Exercise and Sports, Copenhagen, Denmark, ³Steno Diabetes Center Copenhagen, Department of Prevention, Health Promotion and Community Care, Herlev, Denmark, ⁴University of Copenhagen, Department of Public Health, Copenhagen, Denmark

E. IMPLEMENTATION AND SCALABILITY

Purpose: This study focuses on a key component of the Generation Healthy Kids school-based intervention: a free, healthy, and climate-friendly school lunch program. The initiative is supported by pedagogical and practical guidelines aimed at fostering a positive mealtime experience, and school staff receive a four-hour training to prepare for their role as “mealtime hosts.” The study explores how school staff deliver the school lunch program, and mechanisms facilitating or hindering the implementation.

Methods: This abstract draws on data from 11 participant observations in two primary school classes (1st and 2nd grade), along with five informal interviews with staff involved in the lunch program. Descriptive analysis is used to examine how staff deliver the program, while thematic analysis identifies key facilitators and barriers to implementation. Data analysis is ongoing, and additional schools, classes, and staff will be included in the final analysis.

Results: Preliminary findings reveal variation in how staff apply the pedagogical principles: some follow most guidelines, while others apply only a few. Four main themes emerged as influencing implementation: staff’s chosen role during lunch, their authority in the classroom, time allocated for the meal, and the diversity of menus. The analysis also shows that adhering to one principle – such as engaging in conversation with children in a smaller ‘table group’ – can sometimes conflict with others, like promoting a positive attitude toward the served food across the entire class.

Conclusion: Initial results indicate diverse approaches to delivering the lunch program, multiple factors affecting implementation, and challenges in applying all pedagogical principles simultaneously. These insights can inform future adaptations of the program to better support staff and enhance the mealtime experience for children.

II-P-E.19

Community Health Worker Delivered Time-restricted Eating Behavior Change Intervention Piloted for Hispanic Adults to be Scaled with a Lifestyle Intervention

B. Reininger¹, M.V. Saldana¹, L. Mitchell-Bennett¹, A. Muniz¹, S. Garcia¹, M. Najera¹, A. Ramirez¹

¹University of Texas Health Science Center Houston, School of Public Health, Brownsville, United States

Purpose: Time-restricted eating continues to show evidence as an effective weight loss strategy, but little is known about how to disseminate the strategy at the community level. Few TRE interventions are delivered by community health workers (CHWs). This study developed and pilot tested a time-restricted eating intervention delivered by CHWs as part of a larger lifestyle change (physical activity and nutrition) intervention. The pilot study focused on Hispanic adults aged 30-65 years with BMI >25 to determine factors associated with implementation.

Methods: Six Community health workers engaged in a participatory approach to design the health behavior coaching module focused on TRE. The resulting module was pilot tested with 10 Hispanic adults who had no previous experience with TRE in a 4-week pre-post study to examine reach, preliminary effectiveness, adoption, acceptability. Adults with type 2 diabetes, pregnant or breastfeeding, previous or current eating disorder, weight loss medication/surgery or other serious medical conditions were excluded. Measures of TRE adoption, weight, height, blood pressure, hip, waist, overall and visceral body fat, and qualitative measures of implementation were obtained. Ad libitum diet was used for the 4 weeks in combination with TRE recommendations. All participants completed behavioral change coaching modules with CHWs on Sugar, Alcohol, Physical Activity, Fruits/Vegetables, and Portion Control in 2024-2025.

Results: Of the 250 people in the parent study intervention arm, 15 people were offered the the study and 10 consented and enrolled (9 females, 1 male). One individual dropped out of the study. Nine participants adopted TRE behaviors. Qualitative interviews indicated the use of fasting was previously unknown for some, and others had heard of the approach but had not tried TRE prior to intervention. Behavioral coaching provided impetus to attempt the behavior during the study period. Average percent weight loss was 2.8% with weight change ranging from an increase of 1 pound to a decrease of 21 pounds. The average decrease in waist circumference was 3.7 centimeters.

Conclusion: A TRE intervention delivered by CHWs appears to be feasible and acceptable in this population. Preliminary data indicate high adoption, acceptability and weight loss among Hispanic adults recruited from a community lifestyle change behavior intervention.

E. IMPLEMENTATION AND SCALABILITY

II-P-E.20

Is the Level of Implementation Linked with Intervention Outcomes? The Process Evaluation of the Veggie Van Intervention to Improve Diet in Underserved Communities

C. Kasprzak¹, A. Canizares¹, A. Lally¹, R. Paluch¹, L. Vermont¹, L. Tumiel-Berhalter¹, L. Haynes-Maslow², S. Raja¹, A. Ammerman², L. Leone¹

¹University at Buffalo, Buffalo, United States, ²University of North Carolina at Chapel Hill, Chapel Hill, United States

Purpose: The Veggie Van (VV) is a mobile market model that is efficacious in increasing fruit and vegetable (F&V) consumption for lower-income individuals. The model was recently evaluated for its effectiveness in a multi-state trial. Preliminary findings indicated that there were formidable barriers to implementing the model with fidelity. Therefore, we aimed to understand the impact of fidelity to the VV model on our main participant outcomes.

Methods: This was a longitudinal randomized controlled trial conducted in partnership with nine implementing organizations and 699 participants. The primary participant outcome, F&V consumption, was assessed via 24-hour dietary recall and self-reported survey measures at baseline and 12 months. Food security status was assessed using the USDA 10-item screener. Organizations completed monthly surveys designed to capture if core VV model components were implemented; responses were coded and summed to create an implementation score. We conducted correlational analyses between implementation scores and changes in F&V consumption and food security over 12 months. We conducted generalized linear model regression to further explore the association between implementation and diet-related outcomes.

Results: Seventeen market sites implemented the VV model. The mean overall implementation score was 40.6 out of a possible 55 points. Site-level fidelity to the VV model was significantly ($p=0.02$) and positively correlated (Pearson's Correlation Coefficient=0.56) with change in mean F&V consumption over 12 months. The monthly sub-score of nutrition education was also positively (PCC=0.81) and significantly ($p<.0001$) correlated with change in mean F&V consumption. These significant associations remained in regression models. In addition, operating a market for 10 or more months out of the year resulted in 76% greater odds of participants frequenting the mobile market at least once ($p=0.04$). There were no significant associations between implementation and changes in food security.

Conclusion: Understanding fidelity to the VV model can help explain not observing significant differences in main outcome analyses. Implementation support, such as tailored technical assistance, can be tailored to support the components that are most impactful on F&V consumption.

II-P-E.21

Perceptions of Dietary Information among Korean Adults: Insights from Cognitive Interviews

S.K. Choi¹

¹University of Seoul, Graduate School of Urban Public Health, Seoul, Korea, Republic of

Purpose: Despite the proliferation of dietary information from various sources, limited research has examined how individuals perceive such information. This study aimed to explore the perceptions of dietary information among Korean adults, drawing on cognitive interviews conducted during the development of measurement tools related dietary information.

Methods: Cognitive interviews were conducted with 28 adults. The interviews focused on the cognitive processes involved in responding to each item using verbal probing. All sessions were audio-recorded, transcribed, and analyzed using qualitative thematic analysis.

Results: Three main themes emerged. (1) The cognitive distinction between scientific 'nutrition' and experiential 'food': participants interpreted the term 'nutrition' as scientific knowledge—encompassing nutrition labels, caloric and nutrient values, and research findings—often leading to perceived difficulty. In contrast, items concerning 'food' or 'diets' prompted participants to draw upon experiential knowledge from daily life, such as grocery shopping and routine dietary habits, resulting in ease of understanding. (2) The conceptual separation of 'recommendations' and 'information' based on source authority: Respondents identified 'recommendations' as formal, evidence-based dietary advice provided by authoritative institutions, such as government agencies, medical professionals or dietitians. Conversely, 'information' was viewed as informal, non-authoritative content disseminated through media and informal interpersonal sources. (3) Individualized dietary needs beyond standardized recommendations:

E. IMPLEMENTATION AND SCALABILITY

respondents emphasized that ideal diets are highly individualized. While they recognized the credibility of official sources, they expressed a preference for selectively adopting dietary recommendations rather than following them unconditionally. Importantly, this selective approach was not a result of information overload or cognitive burden; rather, it stemmed from the perception that standardized dietary recommendations fail to account for the unique health statuses and socio-economic contexts of individuals.

Conclusion: This study underscores the importance of terminological precision in nutrition research and interventions. Since individuals apply more demanding cognitive standards to terms such as ‚nutrition‘ and ‚recommendations,‘ the imprecise use of terminology in survey tools or interventions may induce response bias or decrease engagement. Furthermore, future nutrition interventions should move beyond standardized guidelines toward more personalized and contextually tailored communication strategies.[This work was supported by the Ministry of Education of the Republic of Korea and the National Research Foundation of Korea(NRF-2025S1A5A8009958).]

II-P-E.22

Development and Internal Validation of a Prediction Model for Successful Weight Loss in Adults Referred to Hospital-based Lifestyle Front Offices Using Routine Clinical Data

H.C. van Essen¹

¹Amsterdam UMC, Public and Occupational Health, Amsterdam, Netherlands

Purpose: Lifestyle interventions are effective for weight loss, yet individual responses vary substantially. Prediction models that estimate an individual's probability of achieving successful weight loss ($\geq 5\%$ initial body weight) could inform personalized care and clinical decision-making. Existing models often depend on complex or non-routine biomarkers. This study aims to develop and internally validate a prediction model, based solely on routinely collected characteristics, to estimate the probability of successful weight loss after 12 months among adults referred to hospital-based lifestyle front offices (LFOs).

Methods: A secondary analysis will be conducted using data from the LOFIT multicentre randomized controlled trial ($n \approx 350$), including adults with overweight ($BMI \geq 25 \text{ kg/m}^2$) referred to an LFO. Candidate predictors comprise sociodemographic, anthropometric, vital sign, behavioural, psychosocial and clinical history variables available at baseline. Predictors with substantial missing data ($>40\%$) will be excluded and remaining missing values addressed using multiple imputation. Penalized logistic regression (LASSO) will be used for model development, with coefficients pooled across imputed datasets. Internal validation will be performed using bootstrap resampling. Model performance will be evaluated by discrimination (AUROC), calibration (intercept, slope, plots), and clinical utility (decision curve analysis). Sensitivity analyses will be conducted both by stratifying model development and performance by intervention versus control group, as well as by applying alternative outcome definitions (e.g., $\geq 10\%$ weight loss, Fuster-BEWAT improvement, remission of metabolic syndrome). This will allow to assess the robustness and clinical utility of the model across different treatment pathways and success criteria.

Results: The resulting model, developed from routinely available characteristics, is anticipated to demonstrate acceptable discrimination and calibration for predicting successful weight loss in patients referred to an LFO. Core predictors such as age, anthropometric measures and behavioural factors are expected to play an important role in model performance. Sensitivity and subgroup analyses will further explore the robustness of predictors and model performance across alternative outcome definitions and patient subgroups.

Conclusion: The resulting model will allow clinicians to estimate an individual's probability of achieving successful weight loss after lifestyle intervention, supporting tailored guidance and identifying patients who may require more intensive support.

E. IMPLEMENTATION AND SCALABILITY

II-P-E.24

Evaluating a Physical Activity-based Intervention for Adults with Intellectual Disabilities: A Cross-sectional Study of Day Service Staff Using the NoMAD Questionnaire to Assess Sustainability Potential

H. Mc Cready¹, K. VanSomeren¹, B. Fitzpatrick², S. Martin³

¹Atlantic Technological University, Donegal, Ireland, ²University of Ulster, Derry, United Kingdom, ³No Barriers Foundation, Donegal, Ireland

Purpose: This study examined the sustainability potential of a physical-activity based intervention within intellectual disability day services targetting the health disparities that exist in the physical health and activity levels of adults with intellectual disabilities. Whilst many interventions have been developed of late, few are evaluated from an implementation perspective, leaving a gap from theory to practise. This is the first application of Normalisation Process Theory together with its validated Normalisation Measure Development (NoMAD) questionnaire in an intellectual disabilities day service staff cohort.

Methods: Guided by NPT, a cross-sectional online survey was conducted with day service staff that supported service users to engage in a physical activity-based health intervention. Convenience sampling was used within an intellectual disabilities day service setting. Following an information session, staff accessed the anonymous survey via QR code and provided electronic consent (n=36). Implementation processes were measured using the NoMAD questionnaire. Personal physical activity was assessed using the Single-Item Measure (0–7 days/week). Descriptive statistics summarised responses, internal consistency was assessed using Cronbach's α , and Spearman's rank-order correlation examined associations between physical activity and overall normalisation score.

Results: The NoMAD demonstrated good internal consistency for the total score ($\alpha = .86$), cognitive participation ($\alpha = .85$), and reflexive monitoring ($\alpha = .89$), with lower reliability for coherence ($\alpha = .48$) and collective action ($\alpha = .57$). Mean scores (1–5 scale) were highest for cognitive participation (M = 4.65, SD = 0.47) and coherence (M = 4.29, SD = 0.46), moderate for reflexive monitoring (M = 3.64, SD = 0.65) and collective action (M = 3.45, SD = 0.53). The overall normalisation score was high (M = 4.40, SD = 0.43). Personal physical activity was not associated with normalisation ($\rho = .13$, $p = .451$).

Conclusion: Findings indicated high overall normalisation, suggesting the intervention was broadly integrated into routine staff practise. Staff understood the purpose and value of the intervention and may view it as an extension of existing practise, rather than a novel departure. The intervention worked within existing staff roles and systems, and staff were committed to engaging with and sustaining the intervention. The NoMAD was a useful instrument to measure the potential for intervention sustainability in the applied setting.

II-P-E.25

Reducing Physical Inactivity and Sedentary Time through a Digital Diabetes Prevention Intervention in Obese Adults with Prediabetes

M. Ho¹, J. Rong¹

¹The University of Hong Kong, LKS Faculty of Medicine, School of Nursing, Hong Kong, Hong Kong, SAR of China

Purpose: Physical inactivity and sedentary behaviour are established risk factors for type 2 diabetes. This study evaluated the impact of a digitally delivered Diabetes Prevention Program (DPP) on physical activity, weight and glycaemic control among adults with obesity and prediabetes.

Methods: Adults aged 40–60 years with obesity and prediabetes were enrolled in a 1-year smartphone-based lifestyle intervention using a pre–post study design. The intervention targeted $\geq 5\%$ weight loss and comprised an intensive phase (0–6 months) followed by a maintenance phase (7–12 months). Participants accessed online videos (weekly during the intensive phase and monthly during the maintenance phase) and self-monitoring tools (goal setting and tracking of diet, physical activity, and anthropometric and biochemical indicators) via a mobile application. PA (Chinese version of the International Physical Activity Questionnaire–Short Form), weight, body fat percentage, and glycaemic control (HbA1c) were assessed at baseline, 6 months, and 12 months. Paired t-tests were performed.

Results: A total of 343 participants enrolled in the study (mean age= 53.1 years, 65.9% female, mean BMI=28.2kg/m²). At baseline, 52.2% participants reporting not engaging in any moderate-to-vigorous PA (MVPA), and only 17.3% participants reported performing ≥ 150 minutes of MVPA/week. After 1-year intervention, the proportion of participants reporting not engaging in any MVPA significantly decreased to 30.8% ($P < 0.001$), while participants reporting engaging

E. IMPLEMENTATION AND SCALABILITY

in ≥ 150 minutes of MVPA increased to 22.6% ($P=0.127$). Mean daily sitting time decreased from 419 (SD=212) minutes at baseline to 374 (SD= 174) minutes at 12-month assessment ($P<0.001$). Participants who have completed the study experienced statistically significant reductions in body weight (mean difference=-1.08, SD 3.51kg, $P<0.001$) and body fat % ($-0.57 \pm 3.33\%$, $P= 0.007$). There was no significant change in HbA1c ($0.02 \pm 0.32\%$, $P=0.204$).

Conclusion: A digitally delivered DPP effectively increased MVPA, reduced sedentary behaviour, and improved weight in physically inactive adults with obesity and prediabetes. Scaling such programs within routine care and evaluation of their longterm effectiveness, especially on glycemic control and costeffectiveness in larger trials are recommended.

II-P-E.26

Implementation and Impact of a Teambased Physical Activity Program in a Predominantly Rural Setting in The United States

B. Daniels^{1,2}, H. Wingo^{1,2}, J. Vincent^{1,2}, V. Lewis^{1,2}

¹University of Arkansas Division of Agriculture Cooperative Extension Service, Family and Consumer Science, Little Rock, AR, United States, ²University of Arkansas, Fayetteville, AR, United States

Purpose: Rural regions of the United States often face financial, geographic, and logistical barriers to accessing structured physical activity opportunities. This study assessed the implementation and health impact of *Walk Across Arkansas* (WAA), a lowcost, scalable, statewide physical activity (PA) intervention delivered in a predominantly rural state in the southcentral United States.

Methods: This crosssectional study recruited participants through word of mouth and social media, and participation was open to anyone. Participants enrolled in self-selected teams and selfreported PA minutes using an online tracking platform or paper logs over eight consecutive weeks in Fall 2025. Program reach was assessed by participant enrollment, geographic coverage, and team participation. Average weekly PA (hours/week) was calculated by age group to examine engagement across the lifespan. A postprogram survey, administered online or via paper, assessed perceived changes in PA and quality of life and included openended questions. Descriptive analyses characterized implementation outcomes and participant responses, and thematic analysis was conducted on qualitative data.

Results: A total of 732 participants (80% female, 8% male, 12% nondisclosed) formed 148 teams representing 50 of Arkansas's 75 counties, demonstrating broad reach. Participants reported 1,657,919 total minutes of PA. Average weekly physical activity ranged from 0 to 4.72 hours/week across age groups, with the highest averages among adults aged 60–69 years ($n = 121$). Engagement was consistent across most age categories, supporting feasibility across the lifespan. Among postprogram survey respondents ($n = 73$), 99% reported program satisfaction, 95% reported increased PA, and 90% reported improved health. Thematic analysis of openended responses ($n = 25$) identified perceived benefits related to physical health, psychosocial wellbeing, and chronic condition selfmanagement.

Conclusion: Preliminary implementation findings indicate WAA achieved promising reach and health impact in a predominantly rural U.S. context. Consistent physical activity engagement across age groups suggests the intervention supports behavior change across the lifespan. This program looks encouraging as a scalable, lowcost PA intervention. Future research should prioritize increasing male and youth participation, utilize device-based PA measures, and evaluate prepost changes in PA and health outcomes.

II-P-E.27

Delivery Typology Shaped Adoption of a Culturally Grounded Early Childhood Health Promotion Program in American Indian Communities

T. Warne^{1,2}, P. Estabrooks³, E. Swenson², E. Webber², J. Merle⁴, A. Adams², E. Tomayko^{2,5}

¹Montana State University, Human Development and Community Health, Bozeman, United States, ²Montana State University, Center for American Indian and Rural Health Excellence, Bozeman, United States, ³University of Utah, Department of Health & Kinesiology, Salt Lake City, United States, ⁴University of Utah, Department of Population Health Sciences, Salt Lake City, United States, ⁵Montana State University, Food Systems, Nutrition & Kinesiology, Bozeman, United States

Purpose: *Turtle Island Tales* is a culturally grounded, evidence-based health promotion program for American Indian families with young children originally tested as a home-mailed intervention. During community-led scale-out, delivery expanded to include classroom-mediated home delivery and classroom-based implementation. With

E. IMPLEMENTATION AND SCALABILITY

adoption defined as the decision by community and organizational partners to initiate *Turtle Island Tales*, this study examined how delivery system adaptations influenced adoption across communities.

Methods: From 2021–2026, implementation was planned with American Indian communities in four U.S. states. Delivery typology, funding source, and implementation support were tracked. Qualitative and quantitative data were recorded through monthly community implementation team meetings, feedback checklists, and focus groups with local partners. Qualitative data were analyzed through an expanded RE-AIM framework, and quantitative adoption counts were summarized across years and states. Descriptive case studies were completed to describe adoption, continuity of participation, and changes in implementation context across communities.

Results: Following a pilot implementation period, adoption was planned in one community in each of four states starting in the 2023/2024 school year. During 2024/2025, adoption increased from two to six communities across four states. Adoption included continued participation from previous communities with four new communities (two planned). In 2025/2026, five communities across two states implemented the program, reflecting a combination of continued adoption and new adopters. Implementation significantly shifted from home delivery to classroom-based models. Adoption decisions were driven by staffing stability, delivery burden, funding mechanisms, and alignment with educational, organizational, or curricular standards. Communities contributed funding support ahead of planned transitions to community-led funding, although this was significantly impacted by the elimination of a government sponsored nutrition education program providing funding assistance.

Conclusion: Delivery system adaptations, specifically the transition from home-mailed to classroom-based delivery, were central to expanded adoption of *Turtle Island Tales*. Adoption increased when delivery aligned with existing educational infrastructure, reducing staffing burden and improving feasibility. Funding stability and implementation support shaped adoption at the organizational level. Scale-out was achieved by adapting delivery structure rather than core program/intervention content, which strengthened sustainability of program delivery in early child education settings in American Indian communities.

F. EARLY CARE AND EDUCATION

I-P-F.02

Relationship between Social Jetlag and Objectively-assessed Lifestyle Habits among 3-4 Year-olds in Japan: The SUNRISE Japan Study

S. Tanaka¹, S. Takemoto², M. Okuda³, M. Takakura^{4,5}, S. Okada⁶, J.J. Reilly⁷, M.S. Tremblay⁸, A. Okely⁹, C. Tanaka¹⁰

¹Kagawa Nutrition University, Faculty of Nutrition, Sakado, Japan, ²Kagawa Nutrition University, Graduate School of Nutrition Sciences, Sakado, Japan, ³Yamaguchi University, Graduate School of Sciences and Technology for Innovation, Yamaguchi, Japan, ⁴University of the Ryukyus, Faculty of Medicine, Ginowan, Japan, ⁵Meio University, Graduate School of Sports and Health Sciences, Nago, Japan, ⁶Physical Education and Medicine Research Foundation, Nagano, Japan, ⁷University of the Ryukyus, Faculty of Medicine, Glasgow, United Kingdom, ⁸Children's Hospital of Eastern Ontario Research Institute, Ottawa, Canada, ⁹University of Wollongong, Faculty of the Arts, Social Sciences and Humanities, School of Health and Society, Wollongong, Australia, ¹⁰Tokyo Kasei Gakuin University, Department of Human Nutrition, Chiyoda-ku, Japan

Purpose: Social jet lag (SJL), which represents the differences during weekday and weekend sleep, has been reported to increase after the school-age years. However, its status, causes, and influences among young children remain unclear. Therefore, the current study aimed to clarify the relationship between SJL and physical activity and sleep among 3- to 4-year-old children in Japan.

Methods: Data from the International Study of Movement Behaviours in the Early Years 2021–2024 (SUNRISE Study - Japan) were utilized. Through kindergartens, daycare centers, or centers for early childhood education and care, 984 children aged 3–4 years participated and wore a triaxial accelerometer (ActiGraph GT3X) for 3–5 days to measure physical activity and sleep durations. Accelerometer data of days with less than 6 hours of sleep periods during the night and less than 6 hours of wear time during waking hours were excluded. Furthermore, data on bed-in and bed-out times during the measurement periods were collected from the parents. SJL was calculated as the difference between the midpoints of time in bed on weekdays and weekends. The minimum number of days for accelerometer and sleep time was set to a minimum of 2 weekdays and 1 weekend day.

Results: After excluding missing values, data for 573 children (age 4.3 ± 0.5 years; 301 boys, 272 girls) were analyzed. Forty children (6.9%) had a SJL of 60 minutes or more, while only 2 (0.3%) had a negative SJL (i.e., midpoint of time in bed on weekends was earlier than that on weekdays) of 60 minutes or more. According to partial correlation analysis adjusted for sex and age, SJL showed a significant but very weak correlation with wake after sleep onset per day (min/day) ($r=0.12$, $p<0.01$) and no correlations with other physical activity or sleep variables. Participants were divided into quartiles according to SJL to compare physical activity and sleep variables, and no significant differences were observed between groups.

Conclusion: SJL in Japanese young children was not as prominent as in school-age children and adolescents. SJL in this sample of young Japanese children showed no important relationships with indicators of sleep or physical activity.

I-P-F.03

Center-level Implementation Predictors of Active Play and Fundamental Movement Skill Practices in Childcare Settings

L.C. Masse¹, O. De-Jongh Gonzalez¹, E.J. Buckler², C. Wright²

¹University of British Columbia, School of Population and Public Health, Vancouver, Canada, ²University of Victoria, Exercise Science, Physical and Health Education, Victoria, Canada

Purpose: Background: Implementation support and organizational structures within childcare centers play a crucial role in shaping educators' ability to integrate active play (AP) and fundamental movement skills (FMS) into daily routines. While individual educator characteristics influence practice, center-level support, such as leadership engagement, goal-setting, and ongoing implementation activities, may be key levers for sustaining AP environments. Objective: To examine whether implementation-related center-level factors, including the presence of an AP champion, frequency of goal review with staff, and levels of implementation support, are associated with educators' reported AP- and FMS-promoting practices.

Methods: A cross-sectional survey was completed by 207 early childhood educators (mean age=41 years; 96% female) representing 59 licensed childcare centers across British Columbia. Center-level predictors included having a champion who promoted AP activities at least every two months (vs. no champion or less frequent), reviewing AP

F. EARLY CARE AND EDUCATION

goals with staff (vs. no goals or goals not reviewed), and moderate or high levels of implementation support (vs. low). Educators self-reported their practices from the previous day, including modeling of AP, outdoor time, number of outdoor sessions, minutes of child AP, and number of FMS facilitated. Covariate-adjusted linear and logistic mixed-effects models accounted for clustering by center.

Results: Centers with an AP champion engaging at least every two months, with goals reviewed with staff, and with high implementation support reported significantly higher numbers of FMS facilitated by educators (OR = 19.04, 10.19, and 8.62, respectively). Additionally, having a champion active at least every two months and moderate or high implementation support were associated with more educator-child AP time (β = 0.60, 0.54, and 0.61, respectively).

Conclusion: Findings highlight the importance of sustained implementation support, leadership engagement, and structured goal-setting in fostering environments conducive to children's AP and skill development. Strengthening these organizational practices may enhance the consistency and quality of physical activity promotion across childcare centers.

I-P-F.04

Early Findings of a Large-scale Reconstruction of Stockholm's Schoolyards to Promote Schoolchildren's Physical Activity

C. Wilén^{1,2}, P. Campos-Garzón^{1,3}, J. Hidalgo Migueles^{1,3}, E. Raffetti^{1,4,5}, K. Rådholm^{6,7}, M. Neovius⁸, M. Dahlén², M. Lundberg¹, P. Tynelius^{1,9}, P. Henriksson⁷, C. Magnusson^{1,9}, V. H. Ahlqvist^{10,11}, D. Berglind^{9,1,2}

¹Karolinska Institutet, Department of Global Public Health, Stockholm, Sweden, ²Stockholm School of Economics, Center for Wellbeing, Welfare and Happiness, Stockholm, Sweden, ³University of Granada, Department of Physical Education and Sports, Granada, Spain, ⁴University of Cambridge, Department of Public Health and Primary Care, Cambridge, United Kingdom, ⁵Uppsala University, Department of Earth Sciences, Uppsala, Sweden, ⁶Linköping University, Primary Health Care Centre Kärna, Linköping, Sweden, ⁷Linköping University, Department of Health, Medicine and Caring Sciences, Linköping, Sweden, ⁸Karolinska Institutet, Department of Medicine, Clinical Epidemiology Division, Stockholm, Sweden, ⁹Region Stockholm, Centre for Epidemiology and Community Medicine, Stockholm, Sweden, ¹⁰Aarhus University, Department of Biomedicine, Aarhus, Denmark, ¹¹Karolinska Institutet, Institute of Environmental Medicine, Stockholm, Sweden

Purpose: Most children do not meet recommended levels of daily physical activity, and the school environment plays an important role in supporting active lifestyles. Schoolyards designed to encourage activity may therefore represent an effective strategy to address this gap. This study examined the early impacts of large-scale schoolyard reconstructions on children's physical activity. Furthermore, the study aimed to explore potential differences between girls and boys. By examining activity before and after the renovations, this study seeks to determine whether these environmental changes promote more active school days and provide insights to guide future schoolyard design.

Methods: This stepped-wedge study design allows each participating school to serve as its own control and intervention site. Between 2024 and 2027, five schools will undergo schoolyard reconstruction each summer, with data collected during the spring both before and after intervention. The study aims to recruit approximately 3,600 children aged 6–12 years from public primary schools in Stockholm. The primary outcome is physical activity, objectively measured using accelerometers. Analyses assessing the effects of the reconstructions on physical activity are ongoing. This abstract presents descriptive statistics from the first five schools, while the results on the effect of the intervention will be presented at the conference.

Results: Pre-intervention, 308 children participated (52.3% girls; mean age = 10.1 years, SD = 1.5), and 473 post-intervention (59.2% girls; mean age = 9.8 years, SD = 1.4). Across both time points, boys were consistently more active than girls during school hours. Boys accumulated 34.5 minutes per day of moderate-to-vigorous physical activity before the intervention (95% CI: 32.2–36.8) and 34.3 minutes after (95% CI: 32.6–36.0), compared with 22.4 minutes (95% CI: 20.2–24.6) and 22.9 minutes (95% CI: 21.4–24.3) among girls. Results examining the effects of the reconstructions will be available before the conference.

Conclusion: Preliminary descriptive findings confirm that boys are more active than girls during school hours. Upcoming analyses will evaluate the effects of schoolyard reconstructions on children's physical activity. This large-scale study has the potential to inform policies and practices in schoolyard design to better promote physical activity among young students.

Investigating the Compliance with the 24-hour Movement Behaviours Guidelines in Preschoolers: Insights from the SUNRISE Pilot Study in Portugal

R. Amaral¹, L. Lemos², K.H. Chong³, L. Roxo¹, W. Silva¹, M.L. Pessoa¹, E. Passos⁴, C. Martins¹

¹Faculty of Sports, University of Porto, Porto, Portugal, ²Lusófona University, Department of Physical Education and Sports, Porto, Portugal, ³Early Start, School of Social Sciences, Faculty of the Arts, Social Sciences and Humanities, University of Wollongong, Wollongong, Australia, ⁴Univerasity of Cape Verde, Departament of Education and Physical Education, Praia, Cape Verde

Purpose: The World Health Organization (WHO) established guidelines on physical activity, sedentary behavior, and sleep for children under 5 years of age. Since then, the SUNRISE Study has been producing evidence on the proportion of children meeting the guidelines and their association to healthy development. This pilot phase of the SUNRISE project in Portugal, aims to: a) report the prevalence of 3- to 4-year-old Portuguese children meeting the WHO guidelines; and b) assess the feasibility and acceptability of implementing the SUNRISE protocol in the Portuguese context.

Methods: A total of 104 preschool children were recruited from three urban and three rural public schools in Portugal. Parents answered questions on the children's screen time and sleep patterns. Movement behaviours were objectively measured using accelerometers wGT3x. Anthropometrics, gross and fine motor skills, physical fitness, and executive functions were assessed using the Sunrise protocol. Children were categorized as compliant or not with the guidelines and descriptive statistics were used to summarize the protocol's feasibility.

Results: The compliance was slightly higher when considering parent-reported sleep data instead of device-based measurements of sleep (33.8% and 31.2%, respectively). When considering the restrained time recommendation, no child was classified as non-compliant. Response rates to the protocol were consistently high - exceeding 70% across all measures.

Conclusion: Compliance with the WHO guidelines among Portuguese children varies depending on the protocol used to assess sleep duration, and the inclusion or not of the restrained time recommendation. The SUNRISE protocol proved to be feasible for implementation in the Portuguese context, and valuable lessons were learned regarding response rates for both accelerometer data and the parent questionnaire.

I-P-F.06

Food Policy, Practice, and Provision in Early Childhood Education and Care: A Scoping Review

A. Turner^{1,2}, A. Porter^{1,3}, M. Murphy⁴, J. Parsonage^{1,2}, J. Coombes^{2,4}, R. Kipping¹

¹University of Bristol, Population Health Sciences, Bristol, United Kingdom, ²National Institute for Health and Care Research (NIHR) School for Public Health Research, London, United Kingdom, ³NIHR Bristol Biomedical Research Centre, University Hospitals Bristol and Weston NHS Foundation Trust and University of Bristol, Uk, United Kingdom, ⁴University of Birmingham, Institute of Applied Health Research, Birmingham, United Kingdom

Purpose: The objective of this scoping review was to evaluate research exploring food policy, practice, and provision in UK Early Childhood Education and Care settings (ECEC). The review will address: (i) how is food policy and guidance used by early childhood education and care settings?; (ii) what food practices are used in early childhood education and care settings in the UK?; and (iii) does food provided and consumed within early childhood education and care settings meet nutritional recommendations for children 0-5 years old? The secondary aim of this review was to map findings from the included studies to the Socio-Ecological Model (SEM) to identify how food policies, practices, and provision in UK ECEC have been explored in research.

Methods: A scoping review was conducted in accordance with the Joanna Briggs Institute (JBI) Methodology for scoping reviews and the Preferred Reporting Items for Systematic Reviews and Meta-analysis for Scoping Reviews (PRISMA-ScR). Five databases were systematically searched. Eligible studies were retrieved after full-text screening. Data were extracted and synthesised based on food policy, practice, and provision concepts and grouped according to SEM level. Results were presented using a narrative summary.

Results: Twenty-four studies were included, the majority had qualitative (n=13, 54%) or cross-sectional study designs (n=11, 46%) and presented findings at the organisational SEM level. Nursery settings were most represented (n=16, 67%), followed by childminders (n=5, 21%), then preschools (n=3, 13%). Studies were conducted in England (n=20,

F. EARLY CARE AND EDUCATION

83%) and Scotland (n=2, 8%), however no studies were undertaken in Wales or Northern Ireland. Studies reported poor adherence to food policies in ECEC and ineffective implementation of Government schemes. Recommended practices were frequently adhered to, however, food provided did not consistently meet nutritional recommendations. Common barriers to implementing healthy food practices and provision were cost, staff shortages, lack of training, and awareness of available guidance.

Conclusion: This review identified a need for research that targets a range of SEM levels, and is conducted in Scotland, Wales, and Northern Ireland. Our findings support the need for increased governmental support for ECEC, through food standards, free meal provision for ECEC, and more accessible nutrition training.

I-P-F.07

Exploring Childcare Movement Behaviour Policy Prevalence, Content, and Associations with Facility Characteristics and Sub-national Legislation

B. Bruijns¹, H. Coyle-Asbil¹, S. Phillips¹, L. Vanderloo², S. Wong¹, P. Tucker¹

¹Western University, London, Canada, ²ParticipACTION, Toronto, Canada

Purpose: Childcare settings play a pivotal role in shaping movement behaviours in early childhood; yet, without national-level guidance on their consideration in childcare programming, regulations vary greatly across Canadian childcare facilities and jurisdictions. This study provides a national overview of written movement behaviour policies in Canadian childcare settings and examines their associations with childcare facility characteristics and provincial/territorial legislation.

Methods: Directors and owners of childcare facilities across Canada ($n = 1,340$) completed a cross-sectional online survey and were asked to report on the presence and characteristics of written policies related to 28 movement behaviour-related items, as well as childcare facility characteristics (e.g., urbanicity, childcare type, enrolment size, daily fees). Descriptive statistics summarized policy prevalence and logistic regression models examined associations between the presence of written movement behaviour policies and facility characteristics, as well as explicit references to movement behaviours in provincial/territorial childcare legislation.

Results: Approximately half of childcare directors/owners reported a written policy addressing overall physical activity (50.0%) and age-appropriate nap duration (46.6%), while 68.7% reported a policy for daily outdoor physical activity and 61.1% reported a policy for providing no screen time. In contrast, policies limiting prolonged seated time (17.0%) were less common. Few directors/owners reported policies addressing educator professional development (<21%) or family education (<12%) related to movement behaviours. Facilities located in jurisdictions with explicit legislative references to movement behaviours were significantly more likely to report written policies across domains ($p < .01$). Urban location ($p = .042$) and smaller enrolment size ($p = .014$) were associated with greater likelihood of overall physical activity and age-appropriate nap duration policies, respectively. Family-/home-based facilities had significantly lower odds of reporting a policy for providing no screen time compared to centre-based programs (OR = 0.19, $p < .001$).

Conclusion: Movement behaviour policies in Canadian childcare settings remain inconsistent and are strongly influenced by governance context and facility characteristics. Strengthening legislative alignment across jurisdictions, implementation supports, and professional learning may help address existing disparities in movement behaviour opportunities for young children in childcare.

I-P-F.08

Associations between 24-hour Movement Behaviors Composition and the Rest-activity Rhythms among Physically Active Preschool-aged Children

X. Huang¹, J. Feng², W.Y. Huang^{1,3}

¹Hong Kong Baptist University, Department of Sports and Health Sciences, Academy of Wellness and Human Development, Kowloon, Hong Kong, SAR of China, ²Ningbo University, Faculty of Sports Science, Ningbo, China, ³Hong Kong Baptist University, Dr Stephen Hui Research Centre for Physical Recreation and Wellness, Kowloon, Hong Kong, SAR of China

Purpose: Rest-activity rhythm reflects the behavioral manifestation of circadian rhythmicity, while movement behaviors function as zeitgebers that entrain the internal biological clock; however, their relationship remains unclear. This study aimed to investigate the associations between 24-hour movement behaviors and rest-activity

F. EARLY CARE AND EDUCATION

rhythm characteristics among physically active preschoolers.

Methods: Baseline data from 84 physically active children aged 3.0 to 5.9 years enrolled in a randomized controlled trial were analyzed. Accelerometer data were processed using the GGIR package in R, from which the 24-hour time-use composition and two cut-point-free metrics (average acceleration and intensity gradient) were derived. Rest-activity rhythm parameters included relative amplitude, inter-daily stability, intra-daily variability, and the circadian function index. Generalized linear models were performed to examine the relationships between movement behaviors and rest-activity rhythm.

Results: More sedentary behavior relative to other behaviors was associated with lower relative amplitude ($\beta = -0.192$; 95% CI: $-0.373, -0.011$), lower interdaily stability ($\beta = -0.184$; 95% CI: $-0.280, -0.089$), higher intradaily variability ($\beta = 0.249$; 95% CI: $0.117, 0.380$), and a lower circadian function index ($\beta = -0.252$; 95% CI: $-0.338, -0.166$). In contrast, more light-intensity physical activity relative to other behaviors was associated with higher interdaily stability, lower intradaily variability, and a higher circadian function index. For cut-point-free metrics, higher average acceleration was associated with higher relative amplitude ($\beta = 0.004$; 95% CI: $0.001, 0.008$), lower intradaily variability ($\beta = -0.005$; 95% CI: $-0.008, -0.001$), and a higher circadian function index ($\beta = 0.005$; 95% CI: $0.002, 0.007$), whereas intensity gradient was positively associated with intra-daily variability ($\beta = 0.270$; 95% CI: $0.005, 0.536$) and inversely associated with a circadian function index ($\beta = -0.214$; 95% CI: $-0.394, -0.034$).

Conclusion: Among physically active preschoolers, greater light-intensity physical activity relative to the remaining behaviors was associated with a more stable and consolidated rest-activity rhythm, whereas a higher relative allocation of sedentary time was linked to a blunted, irregular, and fragmented rhythm. These findings suggest that encouraging light-intensity physical activity and limiting sedentary behaviors may support healthier rest-activity rhythms among physically active children.

I-P-F.09

Development and Initial Validation of the Policy, Systems, and Environment Tool for Early Childhood Nutrition

E.G. Varela¹, A. Mitchell², K. Shelnutt², D. Miller³, A. Mobley¹

¹University of Florida, Health Education and Behavior, Gainesville, United States, ²University of Florida, Family, Youth and Community Sciences, Gainesville, United States, ³University of Florida, College of Education, Gainesville, United States

Purpose: Policy, systems, and environmental (PSE) strategies are widely implemented through community nutrition education programs in early childhood education (ECE) settings to promote healthy eating behaviors. Existing evaluation approaches primarily assess program reach rather than behavioral or sustainability outcomes, limiting understanding of how environmental change influences nutrition behaviors. This study developed an initial content and face validity assessment of the Policy, Systems, and Environmental Strategies Nutrition-Focused Evaluation Survey Tool for Early Childhood Settings (PSE NEST).

Methods: Phase 1 involved item generation. Phase 2 assessed content and face validity using a mixed-methods approach combining individual item rankings and a modified nominal group technique (mNGT). SNAP Ed implementers, PSE specialists, and evaluation professionals working in nutrition education programs nationwide participated in five virtual sessions ($n = 28$; 5 to 7 per group). Participants independently ranked items across four domains, followed by facilitated group discussions to refine wording, response options, and identify missing items. Rankings were summarized descriptively, and qualitative data were analyzed using inductive thematic analysis to support iterative refinement and consensus development.

Results: Findings supported four core measurement domains: PSE strategy characteristics, behavior change, implementation processes, and sustainability. Rankings and group discussion demonstrated consensus on inclusion of items assessing children's exposure to fruits, vegetables, whole grains, and sugar-sweetened beverages; caregiver modeling behaviors including eating the same foods as children and participation in family-style dining; implementation challenges such as staffing, resources, and organizational buy-in; and likelihood of continuing nutrition-supportive practices. Participants emphasized assessing foods offered and consumed to capture behavioral pathways linking environmental change to child dietary behaviors. Sustainability-related items addressing resources, funding, and community partnerships were also prioritized. Participant feedback informed the removal of redundant items and refinement of wording and response options, resulting in a streamlined instrument ready for pilot testing with ECE providers.

Conclusion: The PSE NEST demonstrates initial evidence of content and face validity as a measurement tool for nutrition-focused PSE strategies in early childhood education settings. By integrating behavioral outcomes, implementation processes, and sustainability, it strengthens evaluation capacity within community nutrition

F. EARLY CARE AND EDUCATION

education programs. Future research will assess reliability, psychometric performance, and responsiveness to change through testing in diverse practice settings.

I-P-F.10

Assessing the Association between Combinations of Movement Behaviors and Executive Functioning Outcomes in Preschool-aged Children: A Systematic Review and Meta-analysis

G. Randolph¹, M. Beets¹, G. Weaver¹, E. Adams¹, B. Armstrong¹, M. Savidge¹, O. Finnegan¹, J. White III¹, K. Bowen¹, K. Kiely¹, E. Mainland¹, J. Culverhouse¹, A. Holmes¹, S. Burkart¹

¹University of South Carolina, Exercise Science, Columbia, United States

Purpose: To examine how studies assessing ≥ 2 movement behaviors analyze associations with EF in preschoolers and compare pooled estimates from individual behavior and combination models when available. We hypothesize combined-behavior models would produce different EF associations than single-behavior models. Innovation lies in evaluating analytic approaches, not just effects, across studies measuring multiple behaviors and highlighting gaps between measurement and analysis.

Methods: Three databases were searched for articles published January 2015 – November 2025. Studies included children aged 3-6 years that assessed ≥ 2 movement behaviors and reported EF outcomes in observational designs. Two reviewers completed extraction and quality appraisal. Random-effects meta-analyses were conducted when ≥ 2 studies reported comparable effects. Correlations and standardized regressions were pooled separately for individual behavior and combination models.

Results: Thirty-four studies ($n=18$ - 1,540 participants, mean=293; 82% cross-sectional) met inclusion criteria; 24 provided data for inclusion in the meta-analyses. Although all assessed ≥ 2 movement behaviors, most analyzed behaviors independently. Sixteen studies analyzed behaviors only as independent predictors; eighteen included at least one combination or 24-hour compositions, alongside individual models. Measures were heterogeneous, including objective ($n=21$) and subjective ($n=13$) assessments. Across individual behavior models, pooled associations with EF were small ($r=-0.04$ to 0.12 ; $\beta=0.01$ to 0.11). For combinations of ≥ 2 behaviors, pooled correlations were also small and often non-significant ($r=-0.02$ to 0.10). When combinations were analyzed, pooled correlations remained small: PA + SB (5 studies; $r=0.06$, $p=.003$), PA + sleep (3 studies; $r=0.07$, $p=.051$), PA + screen (2 studies; $r=0.10$, $p<.001$), and 24-hour composition (3 studies; $r=0.06$, $p=.02$). Standardized regression models showed similarly small effects ($\beta=0.03$ - 0.10). **Pooled estimates were comparable across individual and combination models.**

Conclusion: Associations between movement behaviors and EF in preschoolers were small and similar whether examined individually or in combination, likely reflecting heterogeneous measurement and analytic methods. Despite growing interest in multiple movement behaviors, many studies analyzed behaviors individually rather than as integrated 24-hour compositions. Greater consistency in analytic approaches and reporting is needed to determine whether 24-hour day models provide additional insight into EF development.

I-P-F.11

Hong Kong Report Card on 24-Hour Movement Behaviours for Children under 5 Years

W.Y. Huang^{1,2}, M.S. Tremblay^{3,4,5}, S.W. Wong⁶, M.C. Wong⁷, C.H. Sit⁵, D.K. Chan⁸, D. Zhang¹, M. Wan¹, Y. Tang¹, S.H. Wong⁵

¹Hong Kong Baptist University, Department of Sports and Health Sciences, Academy of Wellness and Human Development, Kowloon, Hong Kong, SAR of China, ²Hong Kong Baptist University, Dr Stephen Hui Research Centre for Physical Recreation and Wellness, Kowloon, Hong Kong, SAR of China, ³Children's Hospital of Eastern Ontario Research Institute, Healthy Active Living and Obesity Research Group, Ottawa, Canada, ⁴Active Healthy Kids Global Alliance, Ottawa, Canada, ⁵The Chinese University of Hong Kong, Department of Sports Science and Physical Education, Shatin, Hong Kong, SAR of China, ⁶Physical Fitness Association of Hong Kong, China, Kowloon, Hong Kong, SAR of China, ⁷The Chinese University of Hong Kong, The Jockey Club School of Public Health and Primary Care, Shatin, Hong Kong, SAR of China, ⁸Hong Kong Metropolitan University, Department of Social Sciences, Kowloon, Hong Kong, SAR of China

F. EARLY CARE AND EDUCATION

Purpose: This study presents preliminary findings from the first Hong Kong Report Card on 24-Hour Movement Behaviours for children under 5 years of age. Modelled on the well-established knowledge translation initiative by the Active Healthy Kids Global Alliance, the Report Card aims to provide an evidence-based synthesis of evidence on movement behaviours and related influences among young children.

Methods: The report card evaluates twelve indicators: eight behavioural indicators (Overall Physical Activity, Structured Physical Activity, Active Play, Active Transportation, Sedentary Screen Time, Restrained Time, Sleep, and 24-hour Movement Behaviours) and four sources of influence indicators (Family and Peers, School/Early Childhood Education, Community and Environment, and Government). Each indicator was assigned a letter grade (from A+ to F) based on the best available evidence, following predefined benchmarks established through expert consensus. Data sources from the past ten years included published journal articles, reports from government or non-governmental organisations, and manual searches.

Results: Only one quarter of young children in Hong Kong met the recommended levels of physical activity, resulting in a D- grade assigned for Overall Physical Activity. Approximately half met the age-specific benchmarks for Active Play, Sedentary Screen Time, and Sleep, which corresponded to grades of C, C- and C+, respectively. Fewer than 10% met all recommendations for 24-hour movement behaviours simultaneously, resulting in an F grade for this indicator. The Family and Peers indicator received a C grade, while Early Childhood Education was graded B. The Government indicator was assigned a D+ grade, based on the Health-Enhancing Physical Activity (HEPA) Policy Audit Tool Version 2. Four indicators (Structured Physical Activity, Active Transportation, Restrained Time, Community and Environment) were not graded due to insufficient evidence. Notably, most of the available evidence primarily pertains to preschool-aged children (3-<5 years).

Conclusion: The first Hong Kong Report Card on 24-hour Movement Behaviours for children under 5 years provides a comprehensive, evidence-based synthesis of movement behaviours and their influencing factors among young children. These collated findings can guide policy, practice, research, and surveillance, support international comparisons, and advocate for healthier lifestyles in early childhood.

II-P-F.01

Early Years Lunches in England and Scotland: Associations between Provision, Ultraprocessed Foods (UPF), High in Salt Fat and Sugar (HFSS), Non-core Foods, and Food Consumption

R. Maishman¹, Z. Toumpakari², A. Turner¹, M. Murphy³, C.K Martin⁴, M. Pallan³, K. Hannam¹, P.S Blair¹, S.A Simpson⁵, L. Johnson¹, R. Kipping¹

¹University of Bristol, Bristol Medical School, Bristol, United Kingdom, ²University of Bristol, School for Policy Studies, Bristol, United Kingdom, ³University of Birmingham, Department of Applied Health Sciences, College of Medicine and Health, Birmingham, United Kingdom, ⁴Pennington Biomedical Research Centre, Baton Rouge, United States, ⁵University of Glasgow, MRC/CSO Social & Public Health Sciences Unit, Glasgow, United Kingdom

Purpose: Most young children attend early childhood education and care (ECEC), but little is known about lunch provision, intake and food processing. There are currently no government mandated nutritional standards for ECEC providers in England and a high proportion of children consume packed lunches, demonstrated to be of poor nutritional quality in schools, within these settings. In contrast, Scotland provides universal free meals in ECEC providers with national food standards that must be adhered to. We investigated lunch quality, serving size and consumption within ECECs by provision (packed vs. ECEC provided) using the UK nutrient profile model (high fat, salt or sugar, HFSS), ultraprocessing (UPF) and non-core as food quality measures.

Methods: Lunch intakes of 2-4 year olds attending ECEC (n=52) in England or Scotland were collected using the Remote Food Photography Method in the NAPSACC UK study. Total kcal served, consumed and % total kcal from foods classified as HFSS, UPF or non-core were calculated. Associations between lunch size (served and consumed) and quality with provision type were modelled using multivariable mixed effects linear regression, adjusting for age, zBMI and deprivation level.

Results: Data were available for 532 children; 359 in England (48% packed lunches) and 173 in Scotland (3% packed lunches). Packed lunches had significantly more kcal served than ECEC provided lunches (adjusted mean difference 120.0kcal (95%CI 76.7 to 163.3), p<0.001). A significantly higher proportion of kcal served and consumed were from HFSS foods, UPFs and non-core foods in packed lunches (p<0.01). Higher kcal served, and a higher proportion of kcal served from HFSS foods and non-core foods led to significantly more kcal consumed (p<0.001, p<0.001 and p=0.005, respectively).

Conclusion: Packed lunches had more kcal and contained poorer quality food than ECEC provided lunches, both

F. EARLY CARE AND EDUCATION

features associated with higher food consumption. We reinforce guidance to avoid serving HFSS food and provide appropriate portion sizes initially, to allow children to eat optimal energy intakes. Further research should explore the barriers and opportunities to introduce universal free lunches in ECEC in the UK, the optimum age or age-range for free lunches and pilot the impact and cost-effectiveness of this provision.

II-P-F.02

Strengthening the Application of Evidence to Optimise State-wide Early Childhood Nutrition and Physical Activity Programs

S.L. Yoong¹, M. Lum¹, A. Grady^{2,3}, R. Hodder^{2,3}, A. Bauman⁴, T. Delaney⁵, L. Wolfenden^{2,3}

¹Institute of Health Transformation, Deakin University, Burwood, Australia, ²University of Newcastle, Callaghan, Australia,

³Hunter New England Population Health, Wallsend, Australia, ⁴The University of Sydney, Sydney, Australia, ⁵NSW Ministry of Health, Sydney, Australia

Purpose: Population health prevention programs delivered in early childhood settings are a key public health strategy to equitably improve child physical activity and nutrition. The *Munch & Move* program in New South Wales, Australia, is one of the longest standing programs nationally supporting early childhood education and care (ECEC) services in the state since 2012 to implement sixteen evidence-based healthy eating and physical activity practices. This abstract describes a proactive and deliberate approach by the research team (in collaboration with state funders of the program) to support embedding contemporary evidence to enable ongoing program improvement decisions.

Methods: A multi-method program of research (2018–2025) was designed to generate relevant data to inform decision-making. This included: (1) multiple high quality systematic reviews and a systematic evidence mapping process to identify beneficial ECEC-based nutrition and physical activity components; (2) a state-wide survey with 565 NSW ECEC services to assess implementation of the targeted practices; (3) assessment of scalability and alignment with sector capacity; and, (4) an iterative consultancy process with the state program team to support prioritisation of program components. A targeted engagement strategy, supported by the National Centre of Implementation Science, ensured timely translation of evidence through policy briefs, tailored presentations, and ongoing feedback meetings.

Results: Our four systematic reviews (and subsequent updates) supported identification of 12 evidence-based beneficial components for continued or enhanced implementation. Findings from prevalence and scalability assessments with ECECs were considered together with the state program team to inform the key components of the *NSW Munch & Move* program. Ongoing discussions are continuing to support the optimisation process and development of key indicators, shaping resource development, training, and monitoring processes. In the presentation, we will reflect also on the key elements that enhanced the application of this research in supporting decision making.

Conclusion: This case demonstrates that proactive efforts to collect policy relevant data, targeted engagement, and sustained collaboration can increase application of research evidence into practice. Our experience highlights the importance of long-term research-policy partnerships in ensuring large-scale child health promotion programs remain effective, scalable, and responsive to sector needs.

II-P-F.03

From Second Fiddle to Feeding Partner: Swedish First-time Fathers' Perceptions of their Role in Feeding their Toddler

Y. Törner Le Priol¹, N. Neuman¹, E. Warensjö Lemming¹, A. Ek², P. Nowicka¹

¹Uppsala University, Department of Food Studies, Nutrition and Dietetics, Uppsala, Sweden, ²Karolinska Institutet, Department of Clinical Science, Intervention and Technology (CLINTEC), Division of Pediatrics, Stockholm, Sweden

Purpose: This study explores how first-time fathers in Sweden perceive their role in feeding, focusing on children aged 10 to 24 months. While earlier studies on infant and toddler feeding mainly have included mothers, this study focuses on how paternal roles in early feeding are understood and formed.

Methods: Qualitative interviews with 21 first-time fathers (95 % university degree, 19 % foreign background) of children (57 % girls) aged 10–24 months (mean age 15 months) were transcribed and analyzed using reflexive thematic analysis.

Results: Three themes were developed. The first theme, *The fathers' path into the feeding relationship* captures how the fathers experienced playing second fiddle in the beginning, but felt able to take on a greater role once the child

F. EARLY CARE AND EDUCATION

started eating solid food or when feeding became easier. Some fathers saw the introduction of food as an opportunity to relieve the mothers, while others considered it natural for mothers to take greater responsibility. The second theme, *Striving for equality*, captures the fathers' ambitions and ideals around sharing responsibility for the child's feeding. This included a perceived need for some to "push themselves in" or to be given space by the mothers to establish their own routines. The fathers also expressed feelings of guilt when the mothers took more responsibility. The third theme, *Knowledge, confidence and support* highlights how the fathers' interest in cooking and food shaped their involvement in feeding their child. While some fathers took on significant responsibility driven by a personal interest, others followed the mothers' lead. The fathers experienced that taking paternity leave gave them more confidence and also a bigger role in feeding, but expressed a lack of father-specific support groups, and some of the fathers wished for more individual support from child health care without the mother present.

Conclusion: The study demonstrates that fathers' engagement and role in early childhood feeding are shaped by relational dynamics, paternity leave, and personal motivation. The findings underscore paternity leave as beneficial while fathers express a desire for more targeted support—particularly father-specific groups—to strengthen their confidence and engagement in feeding.

II-P-F.04

Needs of Parents and ECEC Staff of 0-2 Year Old Children Regarding an Intervention Addressing Dietary Behavior, Physical Activity and Sleep

S. Gerards¹, J. Larsen², J. Gubbels¹, S. Brouwers¹

¹Maastricht University, Health Promotion, Maastricht, Netherlands, ²Radboud University, Nijmegen, Netherlands

Purpose: SuperFIT is a widely implemented evidence-based effective multi-component intervention approach targeting parents and Early Childhood Education and Care (ECEC) to improve energy-balance related behaviors of 2-4 year old children in the Netherlands. Based on the needs expressed by parents and professionals working in ECEC, we decided to adapt this intervention to additionally include 0-2 year old children. In the current study, we conducted a needs assessment with parents and other stakeholders to explore their specific needs and preferences regarding the promotion of healthy nutrition, physical activity and sleep in this younger age group, informing the adaptation of SuperFIT for children aged 0-2 years.

Methods: We conducted qualitative semi-structured interviews with >20 parents and other stakeholders (e.g., ECEC staff, experts working with 0-2 year old children, SuperFIT implementers). The interviews were conducted online or in person and focused on stakeholders' needs and possible barriers and facilitators regarding the promotion of nutrition, physical activity and sleep, based on the characteristics categories as categorized by Damschroder in the CFIR model: intervention, individuals, inner setting and outer setting.

Results: First analyses showed that in general parents did not express urgent needs on lifestyle related topics. They did, however, express a need to improve the communication on these topics with ECEC staff members. ECEC staff indicated that they struggled to align the needs of parents with current ECEC policies, particularly regarding sleep. Further detailed results will be presented.

Conclusion: The study will formulate some clear points to be incorporated in the SuperFIT for 0-2 year old children, based on the input of stakeholders, and in line with the existing SuperFIT intervention. Current results will form the basis for the codesign sessions with parents and professionals working in ECEC.

II-P-F.05

Building Responsive Early Childhood Environments in the Canadian Maritime Provinces through CELEBRATE Feeding

M. Rossiter¹, J.-L. McIsaac², J. Campbell³, S. Caldwell⁴, S. Ward Chiasson⁵, L. Mann⁶

¹University of Prince Edward Island, Applied Human Sciences, Charlottetown, Canada, ²Mount Saint Vincent University, Education, Child and Youth Study, Halifax, Canada, ³Dalhousie University, School of Health and Human Performance, Halifax, Canada, ⁴Mount Saint Vincent University, Early Childhood Collaborative Research Centre, Halifax, Canada, ⁵Université de Moncton, École des Sciences des Aliments, de Nutrition et d'Études Familiales, Moncton, Canada, ⁶Mount Saint Vincent University, Applied Human Nutrition, Halifax, Canada

F. EARLY CARE AND EDUCATION

Purpose: There is recent investment in nutrition and early care and education (ECE) through the bilateral commitments in the Canada-Wide Early Learning and Care Agreements, a national school lunch program, and provincial/territorial nutrition policies for ECE settings. However, there is a gap between these policy investments and support for implementation. This presentation will describe the nutrition policy context in Canada alongside of the CELEBRATE Feeding (Coaching in Early Learning Environments to Build a Responsive Approach to Eating and Feeding) intervention that aimed to build capacity for responsive feeding environments to foster children's self-regulation skills related to food.

Methods: Coaches worked collaboratively with ECE programs in the Canadian Maritime Provinces to apply a behaviour change approach to support implementation of responsive feeding with the ECE program context. Using a pre-post mixed-methods design, quantitative and qualitative data were collected to evaluate the six-month intervention. Data sources included baseline/post-intervention observations of feeding environments ($n=16$ classrooms), pre-post educator surveys, interviews, coaching logs, and a six-month follow-up survey. Paired samples t-tests and Wilcoxon signed rank tests assessed changes in overall and individual responsive feeding scores across 21 components (0–3 scale; total 0–63).

Results: The intervention was associated with significant improvements in responsive feeding environments and practices. Observation scores increased from baseline ($M = 38.16$, $SD = 6.55$) to post-intervention ($M = 45.75$, $SD = 5.87$), $t(15) = 4.91$, $p < .001$. Educators reported engaging more frequently in responsive feeding practices and observing positive changes in children's independence and food acceptance. They valued expert guidance, coaching support, and practical tools but noted challenges related to communication, scheduling, and staff turnover. Follow-up data indicated sustained use of key practices across all centres.

Conclusion: There is a timely opportunity to support a growing workforce of educators through recent federal-provincial/territorial commitments to ECE and nutrition. The CELEBRATE Feeding coaching intervention effectively enhanced responsive feeding environments to support implementation of local nutrition standards. Ongoing support and strategies are needed to sustain and scale across ECE settings, ultimately promoting more responsive environments for young children.

II-P-F.07

Prevalence and Correlates of Meeting 24-hour Movement Guidelines among 3-4 Year-Olds in Japan: The SUNRISE Japan Study

C. Tanaka¹, S. Tanaka², M. Okuda³, M. Takakura⁴, S. Okada⁵, J.J. Reilly⁶, M.S. Tremblay⁷, A. Okely⁸

¹Tokyo Kasei Gakuin University, Department of Human Nutrition, Tokyo, Japan, ²Kagawa Nutrition University, Sakado, Japan, ³Yamaguchi University, Ube, Japan, ⁴Meio University, Nago, Japan, ⁵Physical Education and Medicine Research Foundation, Tomi, Japan, ⁶University of Strathclyde, Glasgow, United Kingdom, ⁷Children's Hospital of Eastern Ontario Research Institute, Ottawa, Canada, ⁸University of Wollongong, Wollongong, Australia

Purpose: SUNRISE is an international study of movement behaviours in the early years. In Japan, the main study started in October, 2021 and finished in February 2024. We examined adherence to the World Health Organization's (WHO) Global guidelines for physical activity, sedentary behaviour and sleep for children under 5 years of age in Japan.

Methods: Data on 3 to 4-year-old children from urban and rural areas in Japan were obtained. Physical activity was measured using a triaxial accelerometer (ActiGraph GT3X). Screen time and sleep duration were assessed via parent questionnaire. Meeting the WHO guidelines was defined as participating in, over a 24-hour period: ≥ 180 mins of total physical activity, of which at least 60 minutes was of moderate-to-vigorous intensity physical activity, ≤ 1 hr of sedentary screen time, and 10-13 hrs of sleep (including naps).

Results: Participants included 827 children (4.2 ± 0.5 years-old, girls $n=396$, boys $n=431$; urban $n=437$, rural $n=390$). The proportions of children meeting physical activity, sedentary behaviour, sleep and all guidelines were 35.8%, 14.9%, 87.9% and 4.5%, respectively. A higher proportion of boys than girls met the physical activity guideline (45.9% vs, 24.7%), with average total physical activity and moderate-to-vigorous intensity physical activity in girls (155.4 ± 38.0 min/day and 70.5 ± 23.1 min/day) shorter than in boys (178.2 ± 43.1 min/day and 86.0 ± 28.1 min/day), even after adjustment for age and area (urban or rural). There were no significant differences in meeting sedentary behaviour and sleep recommendations between girls and boys. A higher proportion of children from rural areas (655 ± 51 min/day) than urban areas (647 ± 54 min/day) met the sleep guideline (90.5% vs, 85.6%), with average total sleep time in rural longer than in urban children.

Conclusion: The prevalence of meeting the guidelines was low, mainly due to long periods of sedentary screen time. More physical activity time among boys compared to girls was observed. Living in a rural area was associated with more children meeting the sleep guideline.

II-P-F.08

Effects of Active Outdoor Play Interventions on Movement Behaviours in Preschoolers: A Systematic Review and Meta-analysis

X. Yang¹, J. Feng², Y. Tang¹, K. Ou³, J. Hu⁴, W.Y. Huang^{1,5}

¹Hong Kong Baptist University, Department of Sports and Health Sciences, Academy of Wellness and Human Development, Kowloon, Hong Kong, SAR of China, ²Ningbo University, Faculty of Sports Science, Ningbo, China, ³The Hong Kong Polytechnic University, School of Nursing, Kowloon, Hong Kong, SAR of China, ⁴The Chinese University of Hong Kong, Department of Sports Science and Physical Education, Shatin, Hong Kong, SAR of China, ⁵Hong Kong Baptist University, Dr Stephen Hui Research Centre for Physical Recreation and Wellness, Kowloon, Hong Kong, SAR of China

Purpose: Active outdoor play (AOP) is widely promoted for young children, yet its effects on movement behaviours remain uncertain. This systematic review and meta-analysis aimed to determine the effects of AOP interventions on movement behaviours among preschoolers.

Methods: Six databases (MEDLINE [Ovid], PsycINFO [ProQuest], EMBASE [Ovid], PubMed, Web of Science and SPORTDiscus [EBSCO]) were searched through 27 February 2025. Randomised controlled trials and non-randomised intervention studies examining the effectiveness of AOP interventions on movement behaviours (physical activity [PA], sedentary behaviour [SED]/screen time, or sleep) in healthy preschoolers aged 3 to 6 years were included. Intervention strategies were categorised as: environment-based (modifying outdoor play environments), time-based (modifying outdoor playtime allocation), or combined environment-and-time (both components). Risk of bias was assessed using revised Cochrane tools. Random-effects meta-analyses were conducted using standardised mean differences (SMD) for post-intervention outcomes.

Results: Thirty-five studies were identified; nine studies with 1,409 participants were included in the meta-analysis. Screen time and sleep outcomes were insufficient for synthesis. When pooling all AOP interventions versus usual care (UC), no statistically significant effects were observed for total PA (TPA), moderate-to-vigorous PA (MVPA), light PA (LPA) (each $n = 6$ studies), or SED ($n = 4$), with substantial heterogeneity across outcomes (all $I^2 > 90\%$). In subgroup analyses by intervention strategy versus UC, combined environment-and-time interventions showed significant small-to-medium effects on TPA (SMD = 0.495), LPA (SMD = 0.498), and SED (SMD = -0.495), although each estimate was based on a single study. In contrast, environment-based and time-based interventions did not differ significantly from UC for any outcome; environment-based effects were highly heterogeneous where estimable (all $I^2 > 87\%$), whereas time-based effects showed lower heterogeneity (all $I^2 < 67\%$). In comparisons with teacher-led programmes (brief instruction followed by free play), time-based interventions showed no significant differences across TPA, MVPA, LPA, or SED ($n = 3$ studies).

Conclusion: Overall, evidence was inconclusive regarding the effects of AOP interventions on preschoolers' movement behaviours. Further evidence from high-quality, adequately powered trials is needed to draw firm conclusions regarding the impact of AOP interventions on movement behaviours and expand evidence on sleep and screen time outcomes.

II-P-F.09

Confidence in Evidence for Hong Kong Report Card on 24-Hour Movement Behaviours for Children under 5 Years: Findings from a Novel Structured Rating Tool

Y. Tang¹, D. Zhang¹, M.S. Tremblay^{2,3,4}, S.W. Wong⁵, M.C. Wong⁶, C.H. Sit⁴, D.K. Chan⁷, S.H. Wong⁴, W.Y. Huang^{1,8}

¹Hong Kong Baptist University, Department of Sports and Health Sciences, Academy of Wellness and Human Development, Kowloon, Hong Kong, SAR of China, ²Children's Hospital of Eastern Ontario Research Institute, Healthy Active Living and Obesity Research Group, Ottawa, Canada, ³Active Healthy Kids Global Alliance, Ottawa, Canada, ⁴The Chinese University of Hong Kong, Department of Sports Science and Physical Education, Shatin, Hong Kong, SAR of China, ⁵Physical Fitness Association of Hong Kong, China, Kowloon, Hong Kong, SAR of China, ⁶The Chinese University of Hong Kong, The Jockey Club School of Public Health and Primary Care, Shatin, Hong Kong, SAR of China, ⁷Hong Kong Metropolitan University, Department of Social Sciences, Kowloon, Hong Kong, SAR of China, ⁸Hong Kong Baptist University, Dr Stephen Hui Research Centre for Physical Recreation and Wellness, Kowloon, Hong Kong, SAR of China

Purpose: The Hong Kong Report Card on 24-hour Movement Behaviours for Children under 5 Years provides the first evidence-based assessment for 12 related indicators. This study aimed to conduct a structured quality appraisal by rating the Research Work Group's (RWG) confidence in the data supporting the initial indicator grades.

F. EARLY CARE AND EDUCATION

Methods: Where sufficient data were available, the RWG assigned initial letter grades to indicators based on predefined benchmarks. A confidence rating tool, informed by the confidence ratings used in the Australia Report Card (based on data representativeness and robustness) and supplemented by items from established risk of bias tools, was developed for 11 indicators (excluding the Government indicator). It was used to rate each data source across four domains (representativeness, statistical power, measurement quality, and context and recency). Two researchers rated each data source independently. Scores range from 0 to 14 for behaviour indicators and from 0 to 15 for influence indicators. For each rated indicator, an average score was calculated and then converted to a 1-star (low: 0-5), 2-star (moderate: 6-10), or 3-star (high: ≥ 11) confidence rating.

Results: A total of 21 references, representing 16 unique data sources, were rated across 7/12 indicators that received initial letter grades (Government and indicators with insufficient evidence were excluded). High confidence was assigned only to School/Early Childhood Education. Moderate confidence was assigned to Overall Physical Activity, Active Play, Sedentary Behaviour, Sleep, and Family and Peers indicators. The 24-hour Movement Behaviours indicator was assigned low confidence. Domain-level ratings revealed common limitations across data sources, particularly in the areas of context and recency. The majority of data were collected more than five years ago (12/16), and most behaviour indicators did not account for seasonal variations (11/12).

Conclusion: To the best of our knowledge, this confidence rating tool represents the first structured instrument designed specifically to assess grading decisions for a Report Card. Applying this tool enhances the transparency of grading decisions. The validity and reliability of this tool should be rigorously examined in future studies.

II-P-F.10

Adapting a Home-based Health Promotion Program to Early Educational Settings in American Indian Communities

T. Warne^{1,2}, E. Tomayko^{3,2}, P. Estabrooks⁴, J. Merle⁴, Q. Vickery², E. Swenson², K. Lien², A. Adams²

¹Montana State University, Human Development and Community Health, Bozeman, United States, ²Montana State University, Center for American Indian and Rural Health Excellence, Bozeman, United States, ³Montana State University, Food Systems, Nutrition & Kinesiology, Bozeman, United States, ⁴University of Utah, Department of Health & Kinesiology, Salt Lake City, United States

Purpose: *Turtle Island Tales* is a 12-month evidence-based health promotion intervention for American Indian families with young children originally tested as a home-mailed intervention. Community-led scale-out expanded program delivery to include classroom-based implementation, which necessitated adaptations in program content, structure, and strategy to fit the classroom setting. This study systematically tracked adaptations from the original at-home setting to classroom-based settings serving young children to inform outcomes in this new context.

Methods: *Turtle Island Tales* was implemented in 2023/2024 and 2024/2025 in 6 American Indian communities in four U.S. states as part of a planned phased adoption schedule. Characteristics of program delivery, including adaptations, were systematically tracked during regularly scheduled meetings, feedback checklists, and informal communication with local program delivery partners for each implementation period. Using the Framework for Reporting Adaptations and Modifications–Enhanced (FRAME), multi-level adaptations to content, structure, and delivery strategy were identified. Although effectiveness was not evaluated in the current study, adaptations were systematically linked to anticipated and observed outcomes using the expanded RE-AIM framework to understand implications for expanded reach and sustainment.

Results: Adaptations occurred primarily at the delivery-system and implementation levels, while core content was maintained. Community- and educator-level adaptations emphasized cultural relevance, classroom feasibility, implementation schedule and dosage adjustments, and integration with existing curricula. The research team focused on facilitating delivery in classrooms of up to 20 children ages three to six with adaptations to packaging, classroom feasibility, educator supports, and curriculum alignment with government mandated standards. Most adaptations were planned around limitations identified in the initial adoption phase. Adaptations to content, structure, and delivery strategy were associated with increased reach, adoption, and implementation, and sustained delivery in the classroom setting.

Conclusion: Community-driven transitioning *Turtle Island Tales* from home to classroom delivery required coordinated, practical changes to lesson structure, materials, delivery schedule, and educator supports while maintaining core program content. Next steps include understanding program effectiveness in these settings; however, adaptations allowed the program to fit classroom schedules, group learning environments, curricular requirements and local cultural priorities. Together these changes supported expanded reach and sustained delivery in early care and education settings in American Indian communities.

II-P-F.11

Active Play, Sedentary Time, and Screen Use in Canadian Childcare: A Cross-sectional Analysis of Associations with Childcare Facility Characteristics

B. Bruijns¹, H. Coyle-Asbil¹, S. Phillips¹, L. Vanderloo², P. Tucker¹

¹Western University, London, Canada, ²ParticipACTION, Toronto, Canada

Purpose: Despite childcare settings serving as key environments for supporting physical activity among young children, national-level data on related practices in Canadian childcare contexts remain limited. This study explored physical activity and sedentary behaviour opportunities in Canadian childcare facilities serving young children (<5y) and associations with facility characteristics.

Methods: A cross-sectional online survey employing a modified version of the Play Spaces and Environments for Children's Physical Activity Centre Director and Educator Survey was administered to 1,340 directors/owners of childcare facilities across Canada. Descriptive statistics summarized physical activity and sedentary opportunities and linear regressions explored associations between facility characteristics (childcare type, urbanicity, enrolment size) and duration of daily active play (indoor, outdoor, total, educator-led) and sedentary opportunities (longest bout of seated time, screen time).

Results: Participants reported offering 144.1 (± 99.3) minutes of indoor active play, 127.9 (± 73.0) minutes of outdoor active play, and 250.6 (± 139.0) minutes of total active play daily, with 88.5% of participants offering at least 120 minutes of total daily active play. Outside of meal and nap times, children were expected to sit for a maximum of 19.8 (± 16.7) minutes at a time. Among childcares using screens ($n = 380$), 57.1% noted screen use differed by child age; averages of 5.5 (± 11.8) and 20.2 (± 17.5) min/day were reported for children <2y and 2-4y, respectively. When screen time did not differ by age, an average of 25.4 (± 23.3) min/day was reported. Home-based childcare was associated with more daily indoor active play ($p = .011$), longer bouts of seated time ($p = .001$), and more daily screen time ($p < .001$) compared to centre-based childcare. Urban location was associated with more daily indoor active play ($p = .012$) and total active play ($p = .029$) compared to rural location. No associations were found for outdoor active play or educator-led physical activity.

Conclusion: While most Canadian childcares provide sufficient active play, physical activity and sedentary opportunities varied by childcare type and urbanicity, highlighting the need for targeted strategies to optimize active play, reduce prolonged sitting, and limit screen time across settings.

II-P-F.12

Biopsychosocial Indicators of Adolescent Participants Compared to Non-participants in Structured Sports Programs: A Network Analysis

L. Gandarela¹, Y. Vieira¹, T. Castro², J.C. Nascimento², S. Mascarenhas³, S. Soares⁴, H. Pedrosa³, L. Paixão⁵, M.E. Garcia⁵, P.H. Amaral⁵, V. Menezes³, D. Silva⁵, Centro de Investigação em Saúde, Atividade Física e Esporte - SAFE

¹Federal University of Sergipe, Postgraduate in Health Sciences, Aracaju, Brazil, ²State University of Londrina, Postgraduate in Health Sciences, Londrina, Brazil, ³Federal University of Sergipe, Postgraduate in Movement Science, Aracaju, Brazil, ⁴Federal Institute of Sergipe, Department of Physical Education, Aracaju, Brazil, ⁵Federal University of Sergipe, Department of Physical Education, Aracaju, Brazil

Purpose: To analyze potential differences in the biopsychosocial profile between students who participate and those who do not participate in sports within a public governmental program, using network analysis. Understanding participant profiles improves interventions, maximizes benefits, and expands youth access.

Methods: This cross-sectional study was conducted with adolescents aged 11 to 14 years, allocated into two groups: (1) participants from two structured sports schools ($n = 77$) and (2) students from two public schools who did not participate in these sports schools ($n = 122$). Assessments included anthropometric measures (body mass, height, waist circumference, and somatic maturation), physical fitness tests (standing long jump, sit-and-reach, and one-minute sit-up test), executive function measures (Visual Search, Mental Rotation, Corsi Block-Tapping Task, and Reaction Time Test), psychosocial indicators (sadness, peer rejection, and body image), and behavioral variables (difficulty performing school tasks, weekly Physical Education classes, screen time watching television, weekday and weekend mobile phone use, and number of friends at school). Network analysis was conducted in R using the *qgraph*, *bootnet*, and *ggplot2* packages, applying the EBICglasso estimator (0.1). Networks were estimated and presented using weighted adjacency matrices.

F. EARLY CARE AND EDUCATION

Results: Network analysis revealed structural differences between groups. Students participating in sports programs exhibited a more interconnected network across domains of physical fitness, cognition, behavior, and individual characteristics. A higher frequency of Physical Education classes was positively associated with better reaction time (0.238). Additionally, greater difficulty in completing school tasks was associated with poorer body image perception (-0.239), which was negatively related to waist circumference (-0.067). In contrast, the network of non-participating students presented a more sparse and fragmented structure, with connections concentrated in a smaller number of variable pairs, indicating less integration between the analyzed domains. Greater interaction was observed between the individual and psychosocial domains and physical fitness, with particular emphasis on gender, girls showed a greater correlation with feelings of sadness (-0.123) and boys showed better results in fitness tests, such as jumping (0.240) and sit-ups (0.052).

Conclusion: Participation in structured sports programs was associated with a more integrated pattern of relationships among physical fitness, cognitive performance, behavioral, and psychosocial variables.

Machine-learning Prediction of Obesity from Physical Activity, Sleep, and Screen Use in School-aged Youth

D.A.S. Silva¹, P.d.F. Hinnig², F.d.A.G.d. Vasconcelos², J. Del Pozo-Cruz³

¹Federal University of Santa Catarina, Physical Education, Florianópolis, Brazil, ²Federal University of Santa Catarina, Nutrition, Florianópolis, Brazil, ³University of Seville, Physical Education and Sports, Sevilla, Spain

Purpose: Childhood obesity is multifactorial, and physical activity (PA), sleep, and screen use are common targets of intersectoral prevention efforts. However, the predictive capacity of these movement behaviors remains underexplored. The aim of this study was to assess the predictive performance of PA, sleep duration, and recreational screen-use for obesity among children and adolescents aged 7-14 years in a southern Brazilian city.

Methods: Cross-sectional study with 1,449 participants (56% female) from Florianópolis, Brazil. Weight and height were directly measured to compute body mass index (BMI). Obesity was classified using World Health Organization BMI-for-age, sex-specific z-score references. Movement behaviors were self-reported with PA across active play, organized sports, and household chores, sleep hours on weekdays and weekends, and prior-day use of computer, smartphone, video games, or television. Sex, age, and maternal schooling were included as predictors. Sex-by-movement behavior interaction terms were engineered and tested, and included as candidate predictors in all models. The sample was split into training (70%) and test (30%) sets. Four machine learning (ML) models, LASSO, Elastic Net (ENet), Random Forest (RF), and Gradient Boosting (GB) were evaluated using area under the ROC curve (AUC), sensitivity, and specificity.

Results: All ML models showed moderate discrimination for obesity (AUC 0.62 [GB] to 0.65 [RF]). ENet (sensitivity = 0.76) and GB (sensitivity = 0.84) yielded the highest sensitivities, whereas LASSO achieved the highest specificity (0.89). Across models, consistent predictors of obesity were lower maternal schooling, male sex, younger age, and recreational screen use among males. PA and sleep were not significant independent predictors.

Conclusion: Recreational screen use, particularly among males, emerged as a predictor of obesity in school-aged youth. Movement behaviors showed limited utility for individual screening, indicating that prevention efforts should prioritize reducing screen time and consider sex-specific strategies.

I-P-G.02

Screen Time among Children and Youth with Disabilities: A Systematic Review and Meta-analysis

L.G. Taylor^{1,2}, L.M. Vanderloo^{3,2}, M. Bourke⁴, S.M. Phillips², A. Loh¹, K. Disimino^{5,6}, R.L. Bassett-Gunter^{5,6}, T. Koo⁷, M. Thompson-Hill⁸, P. Tucker^{2,9}

¹Western University, Health and Rehabilitation Sciences, London, Canada, ²Western University, Occupational Therapy, London, Canada, ³ParticipACTION, Toronto, Canada, ⁴The University of Queensland, Health and Wellbeing Centre for Research Innovation, Brisbane, Australia, ⁵York University, School of Kinesiology and Health Science, Toronto, Canada, ⁶York University, LaMarsh Centre for Child and Youth Research, Toronto, Canada, ⁷Western University, Department of Science, London, Canada, ⁸Western University, School of Health Studies, London, Canada, ⁹Children's Health Research Institute, London, Canada

Purpose: Given links between excessive screen time and adverse health outcomes, public health guidelines recommend children under 2 years should not engage in recreational screen time, children 2-4 years should engage in less than 1 hour of recreational screen time per day, and children and youth 5-17 years should engage in less than 2 hours of recreational screen time per day. However, missing from our understanding is the prevalence of screen time for children and youth with disabilities. Low rates of physical activity and high levels of sedentary behaviours in this population mean this cohort may be particularly at-risk for consequences associated with excessive screen time.

Methods: This study examined screen time, and adherence to screen time guidelines, among children (0-17 years) with varying disabilities. Via systematic review and meta-analysis, available data on screen time levels and adherence to screen time guidelines among children and youth with disabilities was searched in $n = 7$ electronic databases. Eligible studies included observational or baseline intervention data reporting recreational screen time among children and youth with disabilities. ASReview, an open-source machine learning model, was used to aid screening of titles and abstracts. Data were extracted by two reviewers and assessed for risk of bias. Random-effects meta-analyses estimated pooled daily screen time and adherence to screen time guidelines by disability types. Subgroup analyses

G. CHILDREN AND FAMILIES

explored age-related differences.

Results: Eighty-one studies representing over 1.2 million participants across 24 countries were included. Most studies focused on children with autism spectrum disorder ($n = 59$), and attention-deficit/hyperactivity disorder ($n = 21$). Screen time ranged from 0.5 to 7.27 hours/day with most children and youth exceeding population-based screen time guidelines. Older children spent more time engaged in recreational screen time than children in the early years (ages 0–4). Screen time also varied substantially by device type with televisions ($n = 135$) being the most reported.

Conclusion: These findings underscore the need for disability-specific interventions that address the unique participation barriers and social contexts of children and youth with disabilities impacting recreational screen use. Standardized screen time measures and targeted public health guidance are essential to measure and promote appropriate screen use behaviours.

I-P-G.03

Identifying Family Movement Behavior Profiles and Associations with Child BMI: Findings from the Pacific Island's Cohort for Cardiometabolic Health (PICCAH) Study in Guam

G. Badowski¹, T. Aflague¹, R.T Leon Guerrero¹

¹University of Guam, Mangilao, Guam

Purpose: Movement behaviors are shaped within family contexts, yet few studies integrate both child and parent behaviors to identify family-level patterns. Using data from the Pacific Island's Cohort for Cardiometabolic Health (PICCAH) study, we aimed to (1) identify family movement behavior profiles using parent and child indicators and (2) examine associations with child BMI in a sample of children aged 4–8 years in Guam.

Methods: We analyzed data from 344 child-parent dyads in the PICCAH study (Guam, 2017–2022) with complete data on 8 movement-related variables: child average daily screen time, parent sitting while watching TV and in other contexts, and five Likert-style indicators of parental monitoring, structure, and support. All variables were standardized and subjected to principal components analysis (PCA). K-means clustering ($k = 3$) was conducted on PCA scores to identify distinct family movement behavior profiles. ANOVAs were used to assess differences in child BMI across profiles, stratified by child age group (4–6 vs 7–8 years).

Results: Principal components analysis (PCA) on eight child and parent behavior variables identified three components explaining 74% of the variance. K-means clustering on these components yielded three distinct family movement profiles. Cluster 1, “Structured & Supportive Parenting” (42%), showed the lowest child screen time (2.9 hrs/day), lower parental sedentary time, and the highest scores on screen time monitoring (3.35), routine (3.46), and limits (3.61). Cluster 2, “High Parent Sedentary / Low Structure” (31%), had the highest parental sitting (6.7 hrs/day TV, 3.4 hrs/day other), moderate child screen use (3.6 hrs/day), and lower monitoring (2.42) and structure (2.80). Cluster 3, “Less Engaged / Moderate Screen” (27%), had the lowest parental engagement (monitoring = 2.09, routine = 2.51, limits = 2.66), moderate child screen time (3.6 hrs/day), and the lowest parental sedentary time. Although BMI differed descriptively across clusters, ANOVA results showed no statistically significant differences in child or parent BMI.

Conclusion: Family movement profiles differed in screen use and engagement but showed no BMI differences. Findings highlight the value of targeting family-level behaviors to support healthy movement patterns in children.

I-P-G.04

Striking the “Sweet-Spot” of 24-hour Movement Behaviors to Achieve Healthy Weight across the Lifespan: A Pooled Data Meta-analysis of Individual Participant Data from 11 Studies

A. Gába¹, T. Hartwig², P. Ševčíková³, T. Sanders⁴, J. Dygrýn³, O. Vencálek³, D. Antczak⁵, J. Conigrave⁶, B. del Pozo Cruz⁷, S. Fairclough⁸, S. Halson⁹, M. Noetel¹⁰, C. Lonsdale⁴

¹Palacký University Olomouc, Faculty of Physical Culture, Olomouc, Czech Republic, ²Australian Catholic University, Strathfield, Australia, ³Palacký University Olomouc, Olomouc, Czech Republic, ⁴Australian Catholic University, Sydney, Australia, ⁵University of Wollongong, Wollongong, Australia, ⁶La Trobe University, Bundoora, Australia, ⁷Universidad Europea de Madrid, Madrid, Spain, ⁸Edge Hill University, Ormskirk, United Kingdom, ⁹Australian Catholic University, Queensland, Australia, ¹⁰The University of Queensland, St Lucia, Australia

G. CHILDREN AND FAMILIES

Purpose: This study aimed to pool individual participant data to identify “sweet-spots” of 24-hour movement behaviors associated with healthy weight.

Methods: Wrist-worn accelerometer data was harmonized for 24-hour movement behaviors collected from 9,818 participants across 11 studies. Reprocessed raw data provided estimates of sleep duration, and time spent in sedentary behavior, light physical activity (LPA), and moderate-to-vigorous physical activity (MVPA). Healthy weight was determined using body mass index and waist circumference. Sweet-spot was defined as the compositional mean of all movement behavior compositions associated with healthy weight. We performed the analysis separately for children, adolescents, adults, and older adults.

Results: Healthy weight was more likely achieved with overall movement behavior composition including 7.3–9.0 hours of sleep, 9.9–12.5 hours of sedentary behavior, complemented by shorter periods of LPA (2.3–3.8 hours) and MVPA (0.7–1.7 hours). Clinically significant differences in sweet-spots were observed for sex, with males requiring less LPA and more MVPA than females. Differences in LPA and MVPA were also observed between socioeconomic groups, although no consistent pattern was identified.

Conclusion: Optimizing movement behaviors presents a promising lifestyle strategy for weight management across the lifespan. However, durations of time required for these behaviors to achieve a healthy weight do not always align with current guidelines, suggesting a potential need to reappraise these recommendations. The observed variations between sex and socioeconomic groups further challenge the “one size fits all” approach, suggesting that more flexible and individualized guidelines are needed to better address individual needs.

I-P-G.05

Collaborative Development of Dynamic School Days: Perspectives from the School Community

J. Nauta¹, A. Berghuis¹, I. Kat¹, K. Koenders¹, K. Moll¹, M. Schweitzer¹, M. Janssen¹

¹*Amsterdam University of Applied Sciences, Professorship Within and Around School, Amsterdam, Netherlands*

Purpose: Short bouts of physical activity during the school day can interrupt sedentary learning and enhance pupils' wellbeing. However, many Dutch schools struggle to implement a dynamic school day. This study supported eight primary schools in developing local dynamic school day implementation plans. We present lessons learned from the developmental process, based on pupils' perspectives, teachers' experiences, and school leaders' views.

Methods: Eight Dutch primary schools participated in an educational program to develop a local dynamic school day. Photo elicitation sessions were conducted with pupils aged 8-9. Pupils guided researchers through their schools, taking polaroid photos of areas where they were physically active or inactive. In follow-up sessions, pupils reviewed the photos and drew activities they wished to engage in within the classroom, school building, and schoolyard. Data were analyzed using the Youth Physical Activity Promotion Model (YPAPM) and shared with schools to guide their implementation plans. At the start of the implementation year, school development teams evaluated the process by creating a timeline. Semi-structured interviews with school leaders explored their experiences and perspectives on implementing dynamic school day policies.

Results: Photo elicitation revealed pupils' perspectives on physical activity opportunities and barriers, including environmental, social, and emotional factors. Semi-structured interviews with school leaders provided insights into policy components realized during the development year. Timeline evaluations highlighted challenges such as balancing curriculum demands, engaging staff, and aligning policies with the school's context.

Conclusion: A structured yet flexible development process is key to creating dynamic school day policies. Incorporating pupils' voices, teachers' experiences, and school leaders' perspectives enabled schools to design context-specific, actionable plans. The yearlong implementation period allowed schools to reflect, adapt, and refine their approaches, demonstrating the value of iterative development and collaboration. Supporting schools through an inclusive and reflective process can lead to more sustainable and effective implementation of dynamic school day policies.

G. CHILDREN AND FAMILIES

¹Baylor College of Medicine, Pediatrics, Houston, United States, ²San Diego State University, Psychology, San Diego, United States, ³University of Newcastle, Centre for Active Living and Learning, Newcastle, Australia, ⁴Baylor College of Medicine, Internal Medicine, Houston, United States, ⁵Baylor College of Medicine, Pediatric Cardiology, Houston, United States

Purpose: Fathers' physical activity (PA) parenting practices are associated with their children being physically active, engaging in PA with their children, and modeling PA for their children. We evaluated fathers' PA parenting practices and their associations with children's sedentary time (ST), light PA (LPA), and moderate-to-vigorous PA (MVPA), using baseline data from the Healthy Dads, Healthy Kids-Hispanic Efficacy Trial.

Methods: Fathers with overweight and obesity (N=187) and their 5-11-year-old children were recruited at churches, clinics, community events, and social media during 2022-2025. Most fathers (48%) reported incomes between \$26,000-\$51,999. Fathers completed a 16-item survey in English or Spanish, on PA parenting practices consisting of 1) Autonomy Promotion (Involvement and Praise subfactors), and 2) Structure (Modeling and Co-participation subfactors). Children who had valid accelerometer data (>600 min/day, 4 days including 1 weekend day, N=170) were included and data were processed for ST, LPA, and MVPA. Three separate structural equation models were conducted to examine the associations between fathers' PA parenting practices and children's ST, LPA, and MVPA, with children's age, sex, and accelerometer wear time as covariates.

Results: Model 1's RMSEA=0.025, CFI=0.997, SRMR=0.057, Model 2's RMSEA=0.026, CFI=0.996, SRMR=0.057, and Model 3's RMSEA=0.038, CFI=0.991, and SRMR=0.057 suggest the data fit to the models was acceptable. There were no significant associations between fathers' Autonomy Promotion ($\beta=0.07$, SE=0.15, 95% CI[-0.24, 0.37], $p=.67$) or Structure ($\beta=0.09$, SE=0.15, 95% CI[-0.20, 0.38], $p=.55$) and children's ST. Children's LPA was not significantly associated with fathers' Autonomy Promotion ($\beta=-0.10$, SE=0.20, 95% CI[-0.49, 0.30], $p=.63$) or Structure ($\beta=0.12$, SE=0.20, 95% CI[-0.26, 0.50], $p=.54$). Children's MVPA was not significantly associated with fathers' Autonomy Promotion ($\beta=-0.05$, SE=0.21, 95% CI[-0.46, 0.35], $p=.79$) or Structure ($\beta=0.21$, SE=0.20, 95% CI[-0.17, 0.60], $p=.29$).

Conclusion: We found no significant associations between Hispanic fathers' PA parenting practices and children's ST and PA levels. Our findings contrast with some previous research and highlight the need to examine other factors that may contribute to children's ST and PA levels. Future studies should investigate other PA parenting practices such as control, logistic support, and the influence of mothers' parenting practices among Hispanic families.

I-P-G.08

Predicting Energy Expenditure in Preschoolers: Evaluating Machine Learning Models, METs Estimation Methods, and their Influence on Activity Classification

H. Coyle-Asbil^{1,2,3}, K. Osojnicki², C. Buck³, J. Burr², D.W. Ma², M.N. Wright³, L.A. Vallis²

¹University of Western Ontario, School of Occupational Therapy, London, Canada, ²University of Guelph, Department of Human Health Sciences, Guelph, Canada, ³Leibniz Institute for Prevention Research and Epidemiology—BIPS, Bremen, Germany

Purpose: The growing use of raw accelerometer data and machine learning presents new opportunities to enhance the utility of wearable data and promote harmonization across datasets (Farrahi & Rostami, 2024). In preschool-aged populations, machine learning has been applied to model and predict physical activity from accelerometer data; however, limited research has compared how these models perform. The purpose of this study was to compare estimates of time spent in different physical activity (PA) intensities derived from activity classification random forest (RF) models and metabolic equivalent (MET)-based models using different approaches to calculate METs.

Methods: Data were obtained from preschool-aged children participating in the Guelph Family Health Study (n=118; ages 3 to <6 years). Children wore an ActiGraph wGT3X-BT accelerometer (100Hz) on their right hip continuously for a week. Two activity classification RFs (Ahmadi et al., 2020b; 2022) were applied in addition to two RFs trained to predict youth-METs (Ahmadi et al., 2020a; Coyle-Asbil et al., 2025), one RF trained to predict adult-METs, and two RFs trained to METs derived from resting metabolic rate (RMR; adjusted Coyle-Asbil et al., 2025 model). Time spent in sedentary (SED), light (LPA), and moderate-to-vigorous (MVPA) activity intensities was compared using repeated-measures ANOVA with Bonferroni-adjusted pairwise comparisons.

Results: The ANOVA indicated that model choice resulted in significant differences in calculated time spent in SED, LPA, and MVPA ($p<.001$). RF models trained to predict youth- or adult-based METs produced unrealistically low SED times (0.4–5.8 min/day) and implausibly high PA estimates (725.99–730.89 min/day). In contrast, RF models trained to predict METs derived from resting metabolic rate (RMR) showed the opposite trend, yielding greater daily SED

G. CHILDREN AND FAMILIES

(438.6–539.8 min/day) and lower PA times (191.1–292.3 min/day). Activity classification models generated the most realistic estimates (SED=300–302 min/day; PA=428.5–430.9 min/day).

Conclusion: Model choice substantially influenced estimates of time spent across activity intensities, emphasizing the importance of methodological consistency. Activity classification models produced estimates within the broad range of METs-based models and yielded the most plausible results under free-living conditions. These findings underscore that public health interpretations may vary considerably depending on the machine learning model applied.

I-P-G.09

Factors Associated with Fundamental Movement Skills among 6-12-Year-Old Children in a Northern Canadian Community

T. Manyanga¹, N. White², G. Marchant³, J. Dumo⁴, G. Faulkner⁵, P.-J. Naylor⁶, C. Pelletier⁷

¹University of Northern British Columbia, Division of Medical Sciences, Prince George, Canada, ²University of Northern British Columbia, Prince George, Canada, ³University of British Columbia, Kelowna, Canada, ⁴Simon Fraser University, Vancouver, Canada, ⁵University of British Columbia, School of Kinesiology, Vancouver, Canada, ⁶University of Victoria, School of Exercise Science, Physical and Health Education, Victoria, Canada, ⁷University of Northern British Columbia, School of Health Sciences, Prince George, Canada

Purpose: Fundamental movement skills (FMS), a core component of physical literacy (PL), develop in childhood and form the foundation for lifelong physical activity (PA). While socio-demographic, behavioral, and environmental factors are known to influence PL, most of the evidence comes from metropolitan settings. This study examined correlates of FMS among children in a medium-sized city in north-central British Columbia, Canada, addressing gaps in understanding FMS development in smaller communities with potentially limited access to organized sport and recreation opportunities.

Methods: This cross-sectional analysis included 166 children aged 6-12 years (66.9% boys; mean age = 8.3 ± 1.7 years) enrolled in short-term community sport programs. FMS (run, hop, overhand throw, kick, balance) were assessed using the PLAYbasic tool (good inter-rater reliability: ICC = .83–.90). Children completed the Physical Activity Questionnaire for Children (PAQ-C) for habitual PA, and parents reported past-week moderate-to-vigorous (MVPA), children's school commute, outdoor play, education, and coached sport participation. Bivariate correlations and multivariable regressions identified predictors of FMS competence.

Results: Most children scored in the “emerging” (70.3%) or “initial” (29.7%) range of FMS competence. In multivariable models, age ($\beta = 2.53$, SE = 0.30, $p < .0001$) and participation in coached sport ($\beta = 8.11$, SE = 1.81, $p < .0001$) were strong independent predictors of total FMS scores, explaining 45.4% of the variance. Parent- and child-reported PA were associated with FMS at the bivariate level but were not significant in adjusted models. Gender differences were minimal overall; however, boys scored higher on kicking ($p = .0003$) and reported higher PAQ-C scores ($p = .05$). In a separate model of kicking FMS scores, a significant age-by-gender interaction emerged, indicating that gender differences were absent in younger children but became more pronounced with age.

Conclusion: Children in this medium-sized city demonstrated generally low FMS competence. Participation in coached sport was the strongest predictor of skill development, highlighting the importance of structured, developmentally appropriate opportunities. The age-by-gender interaction in kicking suggests widening skill gaps with age, likely reflecting cumulative differences in opportunity. Equitable access to inclusive, coached sport programs may be key to advancing physical literacy and lifelong physical activity.

I-P-G.10

Lifestyle Habit Profiles and Emotional Eating in Children and Adolescents of Global Health Program

R. Gaudet¹, C. Lavoie², I. Doré³, T. Barnett⁴, S. Girard¹, N. Carbonneau⁵, R. de Fátima Guimarães¹

¹Université du Québec à Trois-Rivières, Physical Activity Sciences, Trois-Rivières, Canada, ²Université du Québec à Montréal, Psychology, Montréal, Canada, ³Université de Montréal, Montréal, Canada, ⁴McGill University, Family Medicine, Montréal, Canada, ⁵Université du Québec à Trois-Rivières, Psychology, Trois-Rivières, Canada

Purpose: To date, research on lifestyle habits latent subgroups in youth has mainly focused on associations between profiles and psychosocial factors, often omitting to consider sex differences between profiles (i.e., using female-only

G. CHILDREN AND FAMILIES

samples or, at most, using sex as a control variable). The aims of this paper were to a) identify lifestyle habit profiles of adolescents based on sleep, diet, physical activity and screen time; b) explore potential differences in profiles according to sex, age, parental education level, and number of years in the program; c) examine the associations between lifestyle habit profile membership and emotional eating/body dissatisfaction; d) investigate the moderating role of sex in these associations.

Methods: Participants included 581 children and adolescents (6-17 years, $M = 14.05$ years, $SD = 1.68$; 44.1% girls) drawn from the baseline cross-sectional data of the Global Health Program (GHP) quasi-experimental study. Online questionnaires assessed sociodemographic, lifestyle habits, body dissatisfaction and emotional eating variables. Latent Profile Analysis was used to identify underlying participant profiles based on lifestyle habits. Linear regression and moderation analyses were also performed.

Results: Three profiles emerged: 1) “inactive, average lifestyle” ($N = 231$), 2) “healthier lifestyle” ($N = 174$) and 3) “unbalanced lifestyle” ($N = 176$). No meaningful differences in profile composition by sex, age, or parental education level ($p > .05$). Sex modified the association between profile membership and subtypes of emotional eating, but not body dissatisfaction. Girls in the “healthier lifestyle” profile showed less vulnerability to emotional eating (particularly for depressive and comfort) ($EMM = 2.08$, $SE = .10$) than girls in the “unbalanced lifestyle” ($EMM = 2.47$, $SE = .11$), $t(571) = -0.39$, $p = .025$. In contrast, in boys, profiles were not associated with any subtype of emotional eating.

Conclusion: This study identified three lifestyle profiles among GHP participants, showing sex-specific patterns in their associations with emotional eating. These results underscore the need for tailored school and healthcare interventions that integrate sleep, nutrition, physical activity, and mental health to foster balanced and protective routines in youth.

I-P-G.11

Associations between Independent Mobility and Perceived Barriers to Active Commuting to School among Spanish Youth

A. Ramírez-Osuna¹, N. Zurita-Corvalán¹, F.J. Huertas-Delgado², P. Campos-Garzón³, P. Chillón¹

¹University of Granada / Faculty of Sport Sciences, Department of Physical Education and Sports, Granada, Spain,

²University of Granada / Centro de Magisterio La Inmaculada, Granada, Spain, ³Karolinska Institutet, Department of Global Public Health, Stockholm, Sweden

Purpose: Independent mobility to school, defined as youth’s ability to commute without adult supervision, has been associated with greater autonomy among young people. However, its prevalence has declined in recent decades due to safety concerns and features of the built environment. This study examined the associations between independent mobility and perceived barriers to school among Spanish children and adolescents.

Methods: This cross-sectional study, part of the PACO project, included 1,841 participants (52% girls; mean age 13.9 ± 1.4 years) from 27 schools across 11 Spanish cities between 2015 and 2021. The sample comprised 407 children (mean age $= 10.7 \pm 0.6$ years; 49% girls) and 1,434 adolescents (mean age $= 14.6 \pm 0.9$ years; 53% girls). Analyses were conducted separately for children and adolescents. However, given the very low prevalence of independent mobility among children (8%), regression analyses were restricted to the adolescent subsample. Independent mobility was self-reported and defined as commuting to school without adult supervision. Perceived barriers were assessed using the BATACE questionnaire, grouped into two main categories (environmental/safety and planning/psychosocial barriers) and analyzed by category and individual items. Age, sex, and distance to school were self-reported and included as covariates in the models. Logistic regression models examined the associations between perceived barriers and independent mobility.

Results: Among children, only 8% commuted independently, and no significant associations were found between independent mobility and perceived barriers. Among adolescents, 47% reported commuting independently. Higher planning and psychosocial barriers were associated with lower odds of independent mobility ($OR = 0.71$; 95% CI: 0.54–0.95), whereas environmental and safety barriers showed a non-significant positive association ($OR = 1.30$; 95% CI: 0.95–1.79). No significant sex interactions were observed (all $p > 0.45$). At the item level, none of the barriers showed significant associations with independent mobility, but the absence of sidewalks or bike lanes showed a marginal significance ($OR = 1.19$; 95% CI: 0.99–1.43).

Conclusion: The main findings indicated that planning and psychosocial barriers were the most influential factors associated with independent mobility. In contrast, environmental and safety barriers showed no clear association between adolescents with and without independent mobility. Addressing these barriers may help promote adolescents’ autonomy through independent commuting.

I-P-G.12

Influences of Physical Activity Participation amongst Female Tamariki: A Qualitative Investigation of Physical Activity Provider Perspectives

E. Birley¹, R. Batty¹, A. Ali¹

¹Massey University, School of Sport, Exercise and Nutrition, Auckland, New Zealand

Purpose: Physical activity is associated with many physical and mental health benefits for children and adolescents. Despite these recognised benefits, physical activity rates in Aotearoa New Zealand are low amongst children aged 5-11 years (tamariki), with significantly lower participation numbers evident amongst female tamariki. There is a lack of qualitative gender specific research in this area and an identified need to consider various stakeholders perspectives when understanding female tamariki physical activity behaviours. The findings presented herewith are part of a larger ongoing study examining stakeholders' perceptions of female tamariki within the Tāmaki Makaurau Auckland region. Findings specifically focus on the insights of Auckland-based physical activity providers, including their perceptions of barriers to, and facilitators of, participation.

Methods: Semi-structured, in-person interviews were carried out with representatives from physical activity providers across the Tāmaki Makaurau Auckland region. These providers were from a range of settings, including local clubs, regional sport organisations, and a representative regional sports trust. Given the complexities around physical activity behaviours, the socio-ecological model was used as a theoretical framework to guide the interview questions. Interviews were transcribed verbatim, and transcripts sent to participants for member checking. Data was analysed using thematic analysis.

Results: Key themes identified included: meeting the needs of the girls; empowering through leadership; and, reliance on societal support. It was recognised that fun and friendship were key motivators and girls also wanted to have a say in how sessions were run. Although it was noted that girls seem to thrive in an all-girl environment, this was not the case for all with some thriving in a mixed gender setting. The importance of female role models was also perceived as playing a key role in facilitating physical activity. A significant barrier to participation was the funding and implementation of the programmes.

Conclusion: The findings contribute to a more detailed understanding of factors that support and hinder physical activity participation in female tamariki. Such insights could help inform future efforts to support female tamariki to become more active.

I-P-G.13

Nutrition Education in Father-focused Childhood Obesity Prevention Interventions: A Scoping Review

R. Kaur¹, H. Lo², A. Chapleau¹, S. Latkolik¹, P. Morelli¹, I.Y. Park³, B. Lo¹

¹University of Guelph, Department of Family Relations and Applied Nutrition, Guelph, Canada, ²University of California Davis, Department of Nutrition, Davis, United States, ³Chungnam National University, Department of Social Welfare, Daejeon, Korea, Republic of

Purpose: Fathers are increasingly involved in child feeding, yet little is known about how nutrition education is integrated into father-focused childhood obesity prevention interventions. This scoping review is the first to map:

- (1) the extent to which nutrition education is incorporated;
- (2) the nutrition education topics reported;
- (3) the individuals delivering the interventions; and
- (4) the dietary outcomes evaluated.

Methods: A comprehensive literature search was conducted in April 2024 and updated in June 2025 across MEDLINE (Ovid), Web of Science, and CINAHL (EBSCO). Peer-reviewed, English-language articles were included with no restrictions on publication date or geographic location. Eligible interventions were preventive in nature, primarily targeted fathers as the change agent, and incorporated a nutrition education component. Multi-component interventions that concurrently addressed other weight-related behaviours (e.g., physical activity) were also included. Five reviewers independently screened studies and extracted data using a standardized tool developed for this review. Data were analyzed using content analysis following JBI Evidence Synthesis Conduct Standards.

Results: Of the 3,213 titles and abstracts screened, six unique interventions conducted in high-income Western countries met the inclusion criteria. Nutrition education was infrequently emphasized. Three interventions had ≤25%

G. CHILDREN AND FAMILIES

of sessions classified as nutrition-focused; one intervention allocated 26%–50% of sessions to nutrition, another included 51%–75%, and only one devoted >75% of sessions to nutrition-focused content. Commonly reported nutrition education topics were food parenting practices (n=6), goal setting (n=6), energy balance (n=5), national dietary guidelines (n=5), and relapse prevention/maintenance (n=5). Topics central to childhood obesity prevention, such as sugar-sweetened beverages (SSBs) (n=1), fast food (n=2), and fruit and vegetable intake (n=3), were less frequently reported. Many interventions (n=4) were delivered by physical education teachers and research students, with none delivered by registered dietitians. Commonly assessed outcomes included vegetable intake (n=5), SSB intake (n=4), and food parenting practices (n=4).

Conclusion: Few father-focused interventions adequately integrated nutrition education or involved dietitians, highlighting missed opportunities to strengthen fathers' nutrition knowledge and food parenting skills. Future interventions should embed more comprehensive nutrition education, engage registered dietitians, and assess a broader set of dietary outcomes to better support fathers' roles in promoting children's healthy eating and weight-related outcomes.

I-P-G.14

Agreement between the WHO Surveillance Questions on Diet: Estimates of Fruit and Vegetable Consumption Frequencies among Children in Germany and Ireland

A. Hebestreit¹, C. Murrin², H. Pohlabein¹, O. Kilduff², S. Rach¹, I. Rakovac³, K. Castetbon⁴

¹Leibniz Institute for Prevention Research and Epidemiology – BIPS, Bremen, Germany, ²School of Public Health, Physiotherapy and Sports Science, University College Dublin, Dublin, Ireland, ³Division of Prevention and Health Promotion, WHO Regional Office for Europe, Copenhagen, Denmark, ⁴School of Public Health, Université libre de Bruxelles, Bruxelles, Belgium

Purpose: Monitoring fruit and vegetable (F&V) consumption through a harmonized surveillance system is essential for shaping international public health policies. However, comparability of F&V data across national and international surveillance systems is hampered as different instruments are used. Our aim was to study the agreement between COSI and STEPS questions in estimating the frequency of F&V consumption among children.

Methods: In 2022, random samples of pupils were drawn from schools in Germany and Ireland, where data collection followed the COSI protocol. Parents were asked to complete both the COSI questions (a short food frequency questionnaire with six answer options ranging from “never” to “every day, more than once”) and the STEPS questions (open answers indicating the number of days per week), each assessing consumption frequencies of F&V separately. Weighted Kappa coefficients [95% confidence intervals] were computed for the variables into three categories (0-3 days/week, 4-6 days/week, every day). Multivariable binary logistic regression models were used to identify factors associated with agreement between the COSI and STEPS estimates.

Results: Among 4,582 and 4,436 families invited to participate in Germany and Ireland, and after excluding observations with missing data, analyses were conducted on 2,084 entries for fruit and 2,064 for vegetables. The proportion of vegetables consumed at least once/day was 44.7% according to the STEPS question, and 52.5% according to the COSI question. For fruit, these figures were 62.9% and 67.5%, respectively. Weighted kappa coefficients were 0.63 [0.60-0.66] for vegetables and 0.59 [0.56-0.63] for fruit. In separate analyses for F&V, having the highest parental education below a Master's degree (vs. ≥ Master's) or an overweight/obese child (vs. thin/normal weight) were independently associated with reduced agreement (AOR ranging between 0.56 and 0.78). For fruit frequency estimates, lower agreement was observed among families with no native parent (vs. both parents native: AOR= 0.60 [0.46-0.79]) and for COSI frequencies of 0-3 days/week (vs. 7 days/week: AOR= 0.21 [0.16-0.28]) and 4-6 days/week (AOR= 0.45 [0.34-0.59]).

Conclusion: Moderate agreement between existing WHO questions, with notable variability across subgroups, highlights the need for improved wording. Validation studies against comprehensive assessment of diet, such as 24-hours dietary recalls, are required.

G. CHILDREN AND FAMILIES

I-P-G.15

Evaluating Convergent Validity of the Canadian French Version of the Youth Activity Profile (YAP-F)

É. Bédard¹, M. Perera², P. Hibbing³, M. Gagnon¹, M. Pereira da Silva⁴, G. Welk², R. De Fátima Guimarães¹

¹Université du Québec à Trois-Rivières, Physical Activity Science Department, Trois-Rivières, Canada, ²Iowa State University, College of Health and Human Sciences, Ames, United States, ³University of Illinois, College of Applied Health Sciences, Champaign, United States, ⁴Federal University of Rio Grande, Faculty of Medicine of the Federal University of Rio Grande, Natal, Brazil

Purpose: The Youth Activity Profile (YAP) is an online, self-report tool for assessing and promoting physical activity (PA) in schools. This study assessed the convergent validity of a new French translation (YAP-F) with concurrent accelerometry data, as a preliminary test of potential for A) broader use in Canada, and B) cross-cultural applications in YAP-related research.

Methods: Participants were 121 school-aged youth (6-17 y) in Québec, Canada, who wore an ActiGraph activity monitor for 24 hours on seven consecutive days before responding to the YAP-F. The survey provided an array of summary scores describing activity profiles in various segments (school PA, outside-of-school PA, weekday PA, weekend PA and total PA). Segment averages from the YAP-F were compared against temporally matched ActiGraph data processed using Monitor Independent Movement Summaries (MIMS). Average YAP-F scores were categorized into quintiles, and boxplots were constructed to depict the distribution of MIMS within each quintile bin. Emphasis was placed on the descriptive patterns, with correlation coefficients (Pearson r and Spearman ρ) providing quantitative insights on convergent validity.

Results: Boxplots followed the expected monotonic increase, with each successive category of YAP quintile corresponding to a higher median and/or interquartile range of MIMS scores. The correlations varied across school PA ($r=0.35$, $\rho=0.38$), outside-of-school PA ($r=0.13$; $\rho=0.17$), weekday PA ($r=0.20$; $\rho=0.23$), weekend PA ($r=0.38$; $\rho=0.40$), and total PA ($r=0.30$; $\rho=0.32$), with similar patterns and magnitudes for boys and girls.

Conclusion: The YAP-F provided an efficient way to capture data on youth PA patterns, showing promising associations with MIMS in every segment except outside-of-school PA. Our findings support the convergent validity of YAP-F with accelerometry, suggesting there is warrant in further research, including calibration and criterion validation of updated algorithms to predict PA. YAP-F can be reliably used as an assessment tool in PA programming for youth in Québec, Canada, and data can be compared with other regions that utilize YAP for similar purposes.

I-P-G.16

The Home Environment Moderates the Association between Physical Activity Parenting Practices and Children's Moderate-to-Vigorous Physical Activity

S.A. Palmer¹, R.E. Hasson¹, A. Miller², A. Zhang³, I.-M. Lang¹, N. Colabianchi¹, L.E. Robinson¹

¹University of Michigan, Ann Arbor, School of Kinesiology, Ann Arbor, United States, ²University of Michigan, Ann Arbor, School of Public Health, Ann Arbor, United States, ³University of Michigan, Ann Arbor, School of Social Work, Ann Arbor, United States

Purpose: The home environment is a critical but underleveraged setting for promoting children's movement behaviors. This study examined whether physical activity (PA) resources in the home shape children's fundamental motor skills (FMS) and moderate-to-vigorous physical activity (MVPA), and whether these resources enhance the impact of physical activity parenting practices (PAPP).

Methods: This cross-sectional study included parents ($N = 55$, Mage = 39.6 years, 82.6% mothers) of children (Mage = 6.4 years, 55.1% female) enrolled in the Children's Health Activity Motor Program-Afterschool Program (National Institutes of Health NR-01786601) completed the Home Environment Survey. Subscales captured PA Availability (resources present) and PA Accessibility (ease of use). Children completed the Test of Gross Motor Development-3 and wore accelerometers for 7 days.

Results: Linear regression models showed that greater PA Accessibility was unexpectedly associated with lower FMS ($\beta = -0.23$, $p = .030$). In contrast, PA Availability moderated the effect of PAPP on MVPA: when more resources were available, supportive parenting was more strongly linked to children's activity ($\beta = 0.28$, $p = .014$). No moderation effects were observed for FMS.

Conclusion: Findings suggest that increasing the availability of home PA resources can amplify the effectiveness of

G. CHILDREN AND FAMILIES

supportive parenting practices, creating conditions that promote active lifestyles. Translationally, this underscores the need for multilevel interventions that combine parent-focused strategies with efforts to equip homes with accessible resources. Embedding such approaches in family and community programs may accelerate uptake, sustain impact, and bridge research-to-practice gaps in promoting healthy child development.

I-P-G.17

First-Time Parent and Child Health Professional Experiences on Support for Healthy Infant Nutrition and Teeth – Findings from Qualitative Interviews

H. Cheng^{1,2}, J. Appleton^{3,2}, L. Baur^{4,2}, A. Arora⁵, E. Denney-Wilson^{1,2}

¹The University of Sydney, Susan Wakil School of Nursing and Midwifery, Sydney, Australia, ²The University of Sydney, Centre of Research Excellence in Translating Early Prevention of Obesity in Childhood (EPOCH-Translate CRE), Sydney, Australia, ³University of Technology, Sydney, School of Nursing and Midwifery, Sydney, Australia, ⁴The University of Sydney, Discipline of Child and Adolescent Health, Sydney Medical School, Sydney, Australia, ⁵Western Sydney University, School of Health Sciences, Sydney, Australia

Purpose: Overweight, obesity and dental caries (tooth decay) in early childhood are preventable conditions with overlapping aetiologies through nutrition and feeding practices. Formula and bottle feeding behaviours can lead to overfeeding and exposure to free sugars – this includes feeding that is non-responsive to hunger and satiety, such as feeding to sleep or feeding to bottle emptying; or long-term bottle or formula use past 12 months age. Research on formula and bottle feeding remain in weight or dental health silos, with few studies focusing on how parents use non-responsive feeding manage child behaviour.

Understanding the advice provided around healthy eating and dental care—from the perspective of first-time parents and child health professionals—can support the development of communication and messages for supportive and responsive formula or bottle feeding behaviours, to prevent both excess weight gain and tooth decay.

This study aims to explore the beliefs, experiences and practices of first-time parents and child health professionals on supporting healthy nutrition and teeth for infants.

Methods: Semi-structured qualitative interviews were conducted with child and family health nurses and first-time parents of infants aged under 12 months. Inductive thematic analysis, following the Braun and Clarke method, will be undertaken.

Results: To date, 23 first-time mothers and six nurses have been interviewed. All mothers were university educated – most primarily spoke English (n=21) or were born in Australia (n=16). Preliminary analysis indicates mixed awareness on bottle cessation, cup transition, and feeding to sleep, and the association to tooth decay or overfeeding. Parents broadly agreed that healthy teeth and weight in infants were important for holistic and longer-term health outcomes. For parents feeding with bottles, few reported receiving information on paced feeding, or identifying hunger and satiety cues.

Conclusion: Some, but not all, first-time parents recalled receiving information on health nutrition and teeth from professional and social sources. Parents of babies at high risk of excess weight gain and poor dental health need targeted support on responsive parenting, including for sleep and settling, to support healthy teeth and growth. Primary health care providers are ideally situated to provide this support, but other needs may take precedence.

I-P-G.18

Refining the Choosing Health Eating for Infant Health Intervention and Implementation Strategy with Professional and Parent Stakeholders

K. Matvienko-Sikar¹, E. Looney¹, M. Duffy¹, D. Dutch¹, Re-CHERISH Study Team

¹University College Cork, Cork, Ireland

Purpose: The Choosing Healthy Eating for Infant Health (CHERISH) intervention was developed to support healthy infant feeding and prevent childhood obesity. The intervention included brief, consistent, verbal messages delivered by healthcare professionals (HCPs) at primary-care childhood vaccination visits. A feasibility study identified areas for refinement of intervention and trial processes. This study identified and addressed feasibility and implementation issues in the CHERISH recruitment processes and intervention delivery.

Methods: Methods. A multi-phase, mixed-methods approach was employed to include professional and parent needs

G. CHILDREN AND FAMILIES

and perspectives. Phase 1: The multidisciplinary team developed potential refinements to the CHERISH intervention delivery and trial processes. Phase 2: An online survey informed by the Theoretical Framework of Acceptability, was conducted to evaluate parents/caregiver attitudes about proposed refinements. Survey data were analysed using descriptive statistics. Phase 3: Interviews conducted with HCPs (e.g., lactation consultants, midwives) to ensure that parent/caregiver favoured refinements are feasible in practice. Qualitative interview data were analysed using reflexive thematic analysis.

Results: Phase 1 potential refinements involve including other HCPs (e.g., public health nurses (PHNs), and increasing frequency and timing of intervention delivery. In Phase 2, 95 parents/caregivers indicated that including PHNs in intervention delivery, incorporating additional intervention delivery timepoints, online intervention delivery, antenatal recruitment, and updated recruitment processes were feasible and acceptable. Preliminary findings from 19 HCP interviews HCPs indicate that including PHNs in intervention delivery, and additional intervention delivery timepoints are acceptable and feasible. Further interviews are scheduled and analysis of HCP data is ongoing.

Conclusion: Refining and adapting the CHERISH intervention in ways which are acceptable and feasible to HCPs and parents/caregivers is key to maximising the likelihood of successful future implementation and evaluation of the CHERISH intervention.

I-P-G.19

How Do Social Norms Influence Complementary Feeding: A Qualitative Longitudinal Study of Australian Caregivers

A. Scott¹, S. Hunter¹, R. Feo¹, R. Golley¹, B. Johnson¹

¹Flinders University, College of Nursing and Health Sciences, Adelaide, Australia

Purpose: The complementary feeding period (6–23 months) is a critical stage for growth and development, when early eating behaviours begin to form and track into later life. Caregivers play a key role in shaping these early behaviours, yet adherence to complementary feeding recommendations remains low. Social norms are an important but underexplored influence on caregivers' feeding decisions. We aimed to explore how social norms influence complementary feeding practices among Australian caregivers, and how these norms shift across the feeding period.

Methods: A qualitative longitudinal study was conducted with Australian caregivers of infants recruited via social media. Semi-structured online interviews were undertaken when infants were approximately 6, 9, and 12 months old. Interviews explored feeding practices, advice, sources of influence, and perceptions of social norms. Data were analysed using reflexive thematic analysis, informed by discursive insights.

Results: Preliminary analyses of the interviews (n=16-18) identified three themes across timepoints: 1) Diverse complementary feeding norms exist, 2) Norms are ambiguous, 3) Negotiating and managing the norms. At six months, caregivers navigated diverse expectations around timing, feeding approach, and food types. Norms were often unclear but influential, communicated through subtle cues or advice from family, professionals, peers, or social media. By nine months, caregivers navigated expectations to provide "healthy" foods with growing confidence. By twelve months, the influence of social norms had largely reduced, with caregivers balancing health, convenience, and established routines. However, when describing their choices, it became clear that social expectations continued to shape caregivers' language and reasoning, revealing a paradox of perceived independence within ongoing social influence.

Conclusion: This novel research provides a nuanced view of the social context of early food provision, demonstrating how complementary feeding practices reflect an ongoing negotiation between social expectations, professional guidance, and lived realities. The introduction of solids appears to be a critical point for behavioural support, as caregivers are most uncertain and susceptible to social pressures. Recognising and addressing the subtle, ongoing influence of norms through providing stage-specific support, reinforcing positive norms and reducing pressures around "perfect" feeding may strengthen caregiver confidence and promote healthy, sustainable feeding behaviours.

I-P-G.20

Community-guided Adaptation of the LA CASA Nutrition Program for Hispanic Families

M. Rojo¹, B. Ayers¹, E. Feliciano¹, J. Rodriguez¹, A. Pham¹, J. Gittlesohn²

¹University of Arkansas for Medical Science, College of Nursing - Science and Practice Department, Little Rock, United States, ²John Hopkins University, Nutrition, Baltimore, United States

G. CHILDREN AND FAMILIES

Purpose: Childhood obesity is a national crisis, and Hispanic children are disproportionately affected. However, there is a lack of culturally tailored interventions to address these inequities. This presentation will describe the acculturation of the LA CASA (Comunidad, Alimentación, Seguridad y Amén), a nutrition intervention consisting of seven modules developed by the Hispanic community in conjunction with faith-based leaders

Methods: Guided by community-based participatory research principles and the Ecological Validity Model (EVM), we used a qualitative descriptive design and conducted four focus groups (FGs) with 29 participants. They were recruited through purposive sampling from faith-based organizations, the Mexican Consulate, and community organizations. Participants completed an 11-item demographic data sheet. The FGs were guided by the eight domains of the EVM, were conducted in Spanish, audio-recorded, transcribed, and translated. Rapid Analytic techniques were used to analyze the transcripts, and descriptive statistics were used to characterize the sample.

Results: Three FGs were conducted via Zoom and one in person. Average length was two hours. Mean age of the participants was 42 years, mean time living in the US was 12 years, 70% were from Mexico, and 41% spoke Spanish only. Five Themes aligned with the eight EVM domains.

Language and Metaphors: *Translation is insufficient.* Participants noted simple translation was insufficient for meaningful engagement. They recommended providing Spanish-language materials, reducing text density on slides, incorporating familiar food-related terminology, and tailoring content to the community's literacy levels.

Concepts and Content: *Eat well, honor culture.* Participants recommended including images of familiar Hispanic foods and requested colorful, visually appealing materials.

Goals & Methods: *Goals that matter, methods that resonate.* Participants preferred to receive the intervention in trusted and familiar settings, such as churches, and that sessions should not interfere with work or childcare demands. Weekend or evening classes were preferred.

Context and Person: *Grounded in culture, centered on people.* Participants emphasized that the intervention should be delivered by individuals who look like them and have a strong understanding of their cultural background. They also expressed a desire for images that reflected themselves and their families.

Conclusion: Interventions tailored to sub-groups could improve obesity prevalence and increase healthy eating in families.

I-P-G.21

How Can We Increase Physical Activity and Reduce Sedentary Behaviours in Adolescents? The Effects of Three School-based Interventions in Spain

F.J. Huertas-Delgado¹, P. Campos-Garzón², D. Crone³, J. Lamoneda-Prieto⁴

¹Teacher Training Centre La Inmaculada, Granada, Spain, ²University of Granada, Granada, Spain, ³Cardiff Metropolitan University, Cardiff, United Kingdom, ⁴Junta de Andalucía, Cádiz, Spain

Purpose: Active commuting to school offers a valuable opportunity to counteract adolescents' low levels of physical activity. School-based interventions designed and implemented by teachers play a crucial role in fostering behavioural change and promoting healthy habits in this population. This study aimed to evaluate the effects of three distinct school-based intervention programs on usual commuting mode, physical activity, and sedentary behaviour among rural Spanish adolescents.

Methods: A total of 188 adolescents (mean age = 15.81 ± 1.02 years; 45.74% girls) participated in this study. Participants, grouped by class, were assigned to one of three intervention groups or a control group. All three intervention groups followed a Project-Based Learning approach consisting of four phases: planning, implementation, culmination, and evaluation. While sharing a common methodology within Physical Education lessons, the three interventions differed in duration (ranging from three months in Intervention Group 1 [IG1] to a full academic year in IG2 and IG3) and in the types of activities conducted (indoor [IG1 and IG2] vs. outdoor [IG3]). Adolescents self-reported their usual mode of commuting to school, physical activity levels, and sedentary behaviour. The effects of the intervention were examined using multiple linear mixed models.

Results: No significant changes were found in the usual mode of commuting across any group from baseline to follow-up. However, IG1 and IG2 intragroup analysis showed increased physical activity during recess (0.57; 95% CI: 0.08 to 1.06) compared to baseline. Additionally, IG1 demonstrated higher daily physical activity outside school and reduced sitting time (1.23; 95% CI: 0.74 to 1.73), with a medium to large effect size (0.74; 95% CI: 0.32 to 1.16) compared to the control group. Finally, IG3 showed an increase in weekend physical activity (0.39; 95% CI: 0.04 to 0.73) relative to the control group, although with a small effect size (0.30–0.32).

Conclusion: Interventions targeting the mode of commuting may lead to changes in physical activity and sedentary behaviour; however, a longer intervention is not necessarily the most effective. These findings suggest that teacher-led,

G. CHILDREN AND FAMILIES

school-based interventions can successfully promote physical activity and reduce sedentary behaviour, particularly when outdoor activities are incorporated, encouraging active and healthy lifestyles.

I-P-G.22

Analysis of Existing Interventions Stimulating Physical Activity and Motor Competence in 0–4-year-Old Children in the Netherlands Using EBI-mapping

F. Bartels¹, S. Gerards¹, S. Brouwer², S. van Hogen-Koster^{3,4,5}, D. Van Kann^{1,6}, J. Gubbels¹, V. Verbestel¹

¹Maastricht University, Health Promotion - Research Institute for Nutrition and Translational Research in Metabolism (NUTRIM), Maastricht, Netherlands, ²Alfa-college, Practorate Vitality, Groningen, Netherlands, ³Saxion University of Applied Sciences, Healthcare Academy, Enschede, Netherlands, ⁴Medical Spectrum Twente, Medical School Twente, Enschede, Netherlands, ⁵Landstede Groep, Practorate Health, Sports & Exercise, Zwolle, Netherlands, ⁶Fontys University of Applied Sciences, School of Sport Studies, Eindhoven, Netherlands

Purpose: Early childhood (0–4 years) represents an essential period for developing physical activity (PA) habits and motor competence (MC). However, compliance with PA guidelines among young children remains low, and MC levels are declining. Although multiple interventions exist in the Netherlands to promote PA and MC in this age group, there has been no systematic overview of their underlying behaviour change mechanisms. Consequently, it remains unclear how these interventions are expected to work and where opportunities lie for strengthening them. This study therefore applied Evidence-Based Intervention (EBI) Mapping (Walker et al., 2022), a systematic approach, to analyse and understand existing Dutch interventions aiming to promote PA and MC in children aged 0–4 years.

Methods: Following EBI-mapping steps, a qualitative analysis was conducted on Dutch EBIs and best practices. EBIs were identified through a national intervention database, and documentation was systematically analysed to extract the implementation setting, components and underlying behaviour change mechanisms (i.e., determinants and behaviour change techniques (BCTs)). Best practices were identified through advisory council consultation and snowball sampling, followed by semi-structured interviews with intervention owners/developers. Targeted determinants were categorised using the Theoretical Domains Framework, and BCTs were coded using BCT Taxonomy v1.

Results: Twenty-five interventions were included (13 EBIs, 12 best practices). Most were implemented in the childcare setting (n=14) with varying degrees of extension to the home environment. One intervention explicitly integrated multiple settings. Commonly targeted determinants in 0-4-year-old children were environmental context and resources (n=18), skills (n=17) and emotion (n=14), often operationalised through BCTs including adding objects to the environment, behavioural practice/rehearsal, and graded tasks. For environmental change agents (parents and childcare professionals), commonly addressed determinants were knowledge, beliefs about consequences, and skills, with BCTs of instructions on how to perform the behaviour and demonstration of behaviour.

Conclusion: Few Dutch interventions adopt a system-based approach to stimulate PA and MC in young children. EBI-mapping proved valuable for systematically identifying components and mechanisms of existing interventions. Integrating these insights with a broader understanding of needs and perspectives within the ecological system surrounding 0-4-year-olds will reveal opportunities for developing system-based strategies to stimulate MC and PA in these young children.

I-P-G.23

Digital Paths to Prenatal Yoga: The Feasibility of Online Prenatal Yoga in Canadian-living Women

K. Angrish-Dandora¹, P. Perron¹, R. Galati¹, D.K. L. Gammage¹

¹Brock University, Kinesiology, St. Catharines, Canada

Purpose: The 2019 Canadian Prenatal Physical Activity guidelines recommend pregnant women practice prenatal yoga weekly; however, only 15-20% of pregnant women participate in yoga. Reported barriers to prenatal yoga include environmental (e.g., lack of access) and logistical (e.g., time) barriers. While asynchronous (i.e., pre-recorded) prenatal yoga offers addresses some of these barriers, it also has limitations (e.g., no individual feedback, no social interaction), which can be addressed through synchronous (i.e., live) prenatal yoga; no research to date has investigated the feasibility of synchronous online prenatal yoga programs. Thus, this study explored the feasibility

G. CHILDREN AND FAMILIES

and acceptability of a 10-week online synchronous prenatal yoga program.

Methods: The yoga program, designed and taught by a registered yoga teacher (500-hours), consisted of one weekly 45-minute class. Classes included a combination of physical movements, relaxation, and guided visualizations. Indicators of feasibility included recruitment (e.g., number of eligible participants), adherence, retention, number and type of adverse events, and intervention fidelity. Program feasibility and acceptability were assessed using validated measures at 10-weeks, when program evaluation measures were also completed.

Results: Thirty-three pregnant women from across Canada were recruited through maternal health care providers and social media. Eighteen were eligible; however, six dropped out of the program, leaving twelve participants enrolled ($M_{\text{gestational age}} = 19$; $SD = 6.98$). Participants attended an average of 5.27 (2.51) out of 10 classes. Nine women completed all measures at all time points, resulting in a retention rate of 75%. No adverse events were reported, and all classes were delivered as intended. The program was perceived as implementable, but low interest and poor adherence suggest conflicting evidence. Program evaluation data showed that participants chose to join the program, and continued attending, based on its exclusivity to pregnant women, the online setting, the type of physical activity, and free cost.

Conclusion: Given the low interest and poor adherence, significant adjustments to the intervention should be made before further assessing it. Future studies should collaborate with prenatal health care services (e.g., prenatal yoga studios, public health prenatal programs) to increase exposure to online synchronous prenatal yoga programs to increase uptake.

I-P-G.24

Criterion and Convergent Validity of Youth Physical Activity and Sedentary Behavior Questionnaires in Schools' Setting: Current Evidence and Future Perspectives

M. Gagnon¹, S. Bouqartacha¹, É. Bédard¹, L. Delattre¹, M. Descarreaux¹, R.D.F. Guimaraes¹

¹Université du Québec à Trois-Rivières, Physical Activity Sciences, Trois-Rivières, Canada

Purpose: Physical activity (PA) and sedentary behaviour (SB), both valuable for monitoring the health status of the youth individuals, can be assessed using questionnaires that are easy to implement and provide a cost-effective way to collect data. The purpose of this study is to systematically summarize the available studies that evaluate the criterion and convergent validity of questionnaires measuring PA and SB in children and adolescents within school environments.

Methods: A systematic review was conducted to evaluate research that used questionnaires comparing PA and SB to an objective measure among children and adolescents. Studies published in the following databases SPORTDiscuss, Medline, Scopus, ERIC, Academic Search Complete, Education Source and Cochrane Library were searched with no date limits. Studies were eligible for inclusion if they employed self-reported questionnaires among individuals aged between 5 and 20 years and assessed criterion/ convergent validity using an objective measure in a school setting. Studies also had to assess both PA and SB measurements' properties and be written in English. Two researchers (MG-SB) independently screened studies and extracted data. The standardized Consensus-based Standards for the selection of health Measurement INstruments (COSMIN) checklist is used for the studies risk of bias (assessment in progress).

PROSPERO Registration: CRD420251125556

Results: Among 3,278 title and abstract screens, 17 articles examining a total of 12 different questionnaires were included in this review. Within the 17 articles, in addition to the criterion and convergent validities, eight studies also assessed the test-retest reliability, and three studies evaluated the content and construct validity. The validity of questionnaires was generally significantly and moderately correlated to the objective measures, with correlation coefficients ranging from $r=0.11$ to 0.80 , $p=0.20$ to 0.87 ; Bland-Altman plots were $\rho=0.56$ to 0.7 and MAPE results were = 50.6% to 199.6%.

Conclusion: Five questionnaires were identified: PAQ, MARCA, YAP, YPAS and a home-made questionnaire from Bringold-Isler et al. We found conclusive evidence for acceptable validity (moderate to good results) for both PA and SB. More attention on the criterion and convergent validity of PA and SB questionnaires is needed to confirm that questionnaires measure what they intend to measure.

Daytime Sleepiness Is Associated with Physical Activity and Time Spent Sedentary among Chinese Adolescents

J. Moore¹, L. Lu², R. Li³

¹Wake Forest University School of Medicine, Department of Implementation Science, Winston-Salem, United States,

²Emory University, Atlanta, United States, ³Wuhan University, Wuhan, China

Purpose: Understanding the dynamic relationship between sleep, physical activity, and sedentary behavior is essential to addressing the health and well-being of adolescents. Of particular interest, Chinese adolescents are increasingly failing to achieve physical activity and sleep recommendations and engaging in high amounts of sedentary behavior. However, how sleep duration or daytime sleepiness might impact physical activity or sedentary behaviors is unclear. The present study was designed to examine the association between daytime sleepiness, physical activity, and sedentary behaviors among Chinese adolescents in the hopes that these results could inform future interventions.

Methods: A cross-sectional study was conducted at a large secondary school in Wuhan, China. Data were collected using a translated version of questionnaires developed for the Family Life, Activity, Sun, Health, and Eating (FLASHE) study. Daily moderate-to-vigorous physical activity (MVPA) and sedentary time (SED) were estimated using the Youth Activity Profile (YAP), while sleep duration (minutes/night) and daytime sleepiness (1-5, never-always) were assessed using previously validated questions. Two ordinal least squares regression analyses were performed to examine the relationship between daytime sleepiness and PA (model 1) and SED (model 2) while controlling for BMI-z score, grade, gender, income, SED (model 1), PA (model 2), PA barriers/attitude/motivation (model 1), self-efficacy/motivation to reduce SED (model 2), and sleep duration.

Results: A total of 2,750 participants provided complete data for analysis. The results of model 1 indicated that daytime sleepiness was significantly associated with MVPA, with a one-point increase in daytime sleepiness associated with 2-3 minutes less MVPA per day. The results of model 2 indicated that daytime sleepiness was significantly associated with SED, with a one-point increase in daytime sleepiness associated with 3-26 minutes more SED per day.

Conclusion: Understanding the relationship between sleep, daytime sleepiness, physical activity, and sedentary behavior is essential if interventions are to be developed to increase physical activity and decrease sedentary time among Chinese adolescents. Future research should explore these relationships to better understand how they interact and how to better target the problem in future public health interventions.

I-P-G.26

Investigating the Interplay of Movement, Engagement, and Wellbeing in Physically Active Learning Contexts: A Multi-case Study of Elementary Schools in Nova Scotia, Canada

J.E. Campbell¹, S.A. Moore^{1,2,3}, S. Truong¹, D.G. Rainham¹, M.R. Stone¹

¹Dalhousie University, School of Health and Human Performance, Halifax, Canada, ²Dalhousie University, Department of Pediatrics, Faculty of Medicine, Halifax, Canada, ³IWK Health, Pediatric Rehabilitation, Halifax, Canada

Purpose: Physically active learning (PAL) is an emerging movement-based pedagogy in schools beneficial for student learning, physical activity (PA), and wellbeing. However, more research is needed on effective implementation of PAL, specifically where, how long, and in what ways movement is being integrated, and its associated outcomes, especially in the Canadian context. This study explored what types and intensities of PA, and related student behaviours and wellbeing outcomes (i.e., enjoyment, engagement, collaboration) were observed from typical PAL lesson structures, settings, and teacher behaviours (i.e., engagement, instruction).

Methods: A multi-case study was conducted, combining teacher demographics, PAL lesson observations (adapted from Texas Initiatives for Children's Activity and Nutrition Active Lesson Implementation form), and student accelerometry (ActiGraph GT3X+). Data were collected during one full school day among classes (students aged 9-11 years) that regularly implement PAL, as a result of training with the Nova Scotia (NS) Active Smarter Kids Project, across three school regions in NS, Canada. Observation data were examined using within and cross-case analysis. Demographic and movement data were analyzed descriptively, where movement intensities were categorized using Evenson's cut points.

Results: Participating teachers (n=3, all identifying as women) had 11-23 years of teaching and 2-5+ years of PAL experience. PAL lessons ranged from 21-45 minutes, were delivered outdoors on school grounds, and integrated

G. CHILDREN AND FAMILIES

math and/or literacy through relay-style formats involving primarily locomotor movements (e.g., running/walking/climbing). Students were consistently observed to be happy, engaged, and collaborative. Teachers' engagement varied from instructing on the sidelines to interactive, supportive participation. Fifty students (site 1: n=13; site 2: n=16; site 3: n=21) wore accelerometers. PAL lessons contributed 5.6 ± 0.9 minutes of moderate-vigorous PA (MVPA) and 9.6 ± 2.4 minutes of light PA (LPA), representing $15.0\% \pm 4.4\%$ and $9.8\% \pm 2.0\%$ of the total school-day MVPA and LPA, respectively. PAL lessons consistently produced a greater proportion of school-day MVPA than both traditional math classes and morning recess.

Conclusion: PAL lessons facilitated predominantly locomotor movements across varied intensities, aligning with provincial school-based and national movement guidelines and were found to support positive student wellbeing. These findings provide support for the continuation and expansion of PAL as a health-promoting school initiative.

I-P-G.27

Objective Assessment of Differences in Physical Activity and Sleep from School Year to Summer in Children with Intellectual and Developmental Disabilities

K. Kiely¹, R.G. Weaver¹, O. Finnegan¹, J. White III¹, S. Burkhart¹, M. Beets¹, B. Armstrong¹, E. Adams¹, J. Culverhouse¹, M. Savidge¹, G. Randolph¹, K. Bowen¹

¹University of South Carolina, Columbia, United States

Purpose: The Structured Days Hypothesis suggests that structured environments, such as school, help improve physical activity (PA), sedentary time, and sleep, whereas unstructured periods, like summer, contribute to worsening obesogenic behaviors. However, very few studies have applied the SDH to children with intellectual and developmental disabilities (IDD), or objectively measured differences in these behaviors (e.g., physical activity, sedentary time, sleep) from school year to summer in this population.

Methods: Nine children with IDD (8.9 ± 1.8 years, 56% female, 89% White, 56% with obesity, 44% with autism) were recruited from a local community program. This study children's moderate-to-vigorous PA (MVPA), light PA, sedentary time, and sleep (onset/offset time and onset/offset variability) measured via a 14-day waist-worn accelerometry protocol during school (April/May) and summer (June/July). Descriptive statistics were used to describe the sample characteristics and differences in outcome measures from school to summer.

Results: Seven of the nine children provided both school and summer measures with a total of 151 days meeting criteria for analysis (school: 12 days per child, summer: 10 days per child). MVPA aligned with the SDH in 5 of the 7 children with an average of 11.9 minutes/day less MVPA during summer. Light PA aligned with the SDH in 6 of the 7 children with an average of 67.9 minutes/day less light PA during summer. Sedentary time aligned with the SDH in 5 of the 7 children with an average of 16.4 minutes/day increase in sedentary time during summer. Sleep offset time aligned with the SDH across all children with sleep offset occurring 123 minutes later during summer but was more variable in during the school year in 5 of the 7 children. Sleep onset aligned with the SDH in 5 of 7 children with onset occurring 46 minutes later during summer but and was more variable during the summer in 5 of the 7 children.

Conclusion: PA and sleep behaviors aligned with SDH (e.g., improved during the school year) in a majority of this sample of children with IDD. A structured environment, like school, may positively influence PA and shift sleep timing earlier in children with IDD.

I-P-G.29

Two Methods for Personalizing the Delivery of Nutrition Education Based on Adolescent Diet

G. De Mello¹, K. Marstall¹, J. Gardner¹, A. MacMillan Uribe¹, J. Szeszulski¹

¹Texas A&M AgriLife Research, Dallas, United States

Purpose: Consuming the five essential food groups—fruits, vegetables, grains, protein, and dairy—is important for promoting health. However, many adolescents do not follow United States Department of Agriculture guidelines. Personalizing interventions to individual needs (e.g., current eating patterns) may more effectively improve dietary habits than providing general nutritional education. This study compares two approaches to personalizing nutrition education.

G. CHILDREN AND FAMILIES

Methods: Adolescents completed a demographic survey and the SPAN food frequency questionnaire assessing consumption of the recommended amounts of fruits (<3 or ≥3 servings), vegetables (<4 or ≥4), grains (<5 or ≥5), protein (<7 or ≥7), and dairy (<3 or ≥3). Each food group, consumption was dichotomized (Y/N) based on if adolescents were meeting recommendations, and nutrition patterns were evaluated using latent class analysis (LCAs), then labeled according to potential targets for delivering personalized nutrition content.

Results: Only average, adolescents ($n = 133$; 15.7 ± 1.1 years old; 67.4% female) were not meeting recommendations for 3.83 ± 1.10 food groups (range 0-5), and less than half were meeting recommendations for each group: fruit (21.8%), vegetables (37.6%), dairy (5.3%), grain (9.8%), and protein (42.9%). Adolescents were classified into two patterns. Pattern 1, ($n=117$; 87%) was characterized by personalization targets for fruits, vegetables, grains, protein, and dairy. Pattern 2 ($n=18$; 13%) had fruit, grains, and dairy as personalization targets. When comparing the targets identified by the nutrition patterns vs. categories where students were not meeting recommendations, 36.1% matched exactly, 43.6% included one extra target, 21.1% included two extra targets, and 1.5% included three extra targets. On average, the LCAs identified $0.90 \pm .78$ extra targets, which were overestimated across all categories: fruits (21.8%), vegetables (27.8%), dairy (5.3%), grains (9.8%), and protein (29.3%).

Conclusion: Adolescents in this sample exhibited two distinct nutritional patterns; however, they overestimated personalization targets by ~20% (on average, one additional target per person). Still this type of approach could help personalize group education content whereby adolescents could be broken into two groups based on their nutrition profiles. Conversely, digital interventions that offer an opportunity could higher degrees of tailoring may want to use adolescent's individual alignment with dietary recommendations to create personalized nutrition education targets.

I-P-G.31

Parents' Perceptions of Screen Time in Early Childhood: Results from the NavScreen Pilot Study

J. Sandborg¹, F. Segerros¹, M. Löf¹

¹Karolinska Institutet, Department of Medicine, Huddinge, Flemingsberg, Sweden

Purpose: Screen time and its potential health consequences in early childhood (0–5 years) is a rapidly emerging focus area. Despite existing screen time guidelines, evidence-based parental support tools are lacking. The transition from no screen use to allowing limited exposure (e.g., up to one hour daily) during ages 1–3 presents a particular challenge for families. This study explored parents' perceptions to inform the development of a scalable intervention for navigating screen time during this critical period.

Methods: This study, initiated in October 2024, involved semi-structured interviews (online via Teams) with 15 parents of 1–3-year-olds (mean age 22 months), recruited through preschools and convenience/snowball sampling. Participants were predominantly Swedish born mothers with university education. Interviews were audio-recorded, transcribed verbatim, and are being analyzed using inductive thematic analysis.

Results: Preliminary findings reveal recurring patterns in parental perspectives. Parents expressed a need for guidance beyond screen time duration, including content appropriateness and parenting strategies. Most questioned the necessity of screen use at all in this age group, while also distinguishing between “better” and “worse” screen time (e.g., program pace, device type). Most found it manageable to limit screen time but anticipated greater challenges as children grow older, particularly when introducing it for the first time. Simultaneously, several suggested introducing support tools already from birth. Parents reported having family routines or rules, mainly for their child, but also expressed a desire to reduce their own screen time, something they found difficult and to negatively impact parent-child interactions. These results will be used to co-create an intervention, which will be evaluated in a randomized controlled trial that we recently got funding for. We will also present the study design of this trial.

Conclusion: Parents need practical support in navigating screen use, especially when first introduced. Findings highlight the importance of developing scalable interventions that address not only screen time duration but also content and parental habits. Supporting parental screen behavior may improve child screen use and family interactions. The results will be used to inform the new NavScreen intervention that will be evaluated in a full-scale trial in 2026-2028.

I-P-G.32

First Insights into the Effectiveness of the Food Challenge: A Nutrition Education Program for Vocational and Practical Secondary Education

M.C.E. Battjes-Fries¹, M. Weijnen¹, J. de Rijk-Heimerink²

¹Louis Bolk Instituut, Bunnik, Netherlands, ²LekkerBoer, Olst, Netherlands

Purpose: Nutrition education can be an effective strategy for positively influencing adolescent's eating behavior. The Food Challenge is a program developed to improve the eating behavior and lifestyle of students in vocational and practical secondary education. It consists of classroom lessons, guest lectures by students, and an excursion to a farm, during which students, for example, design a healthy poké bowl and take part in a bootcamp. The effectiveness of this program has not been evaluated yet, leaving it unclear to what extent the program achieves its goals. This study aimed to explore the effectiveness of the 2025 edition.

Methods: Using a pretest-posttest design, 89 students in the first two grades from nine schools in the Netherlands participated in the study (ages 12-14, 75% in vocational education). Before and after the program, students completed a digital questionnaire assessing their capacity (knowledge and skills), physical and social opportunity (ability at home and their friends' behavior), and motivation towards seven behaviors related to healthy and sustainable eating and physical activity (mostly measured on 5-point scales), as well as the behaviors themselves (mostly in days per week). Differences between the pretest and posttest scores were analyzed using paired t-tests and Wilcoxon signed-rank tests.

Results: The results demonstrated a few modest changes. Scores on knowledge and physical opportunity related to sustainable behavior ($7\% \pm 3\%$ and 0.18 ± 0.11 , both $p=0.05$) and physical activity behavior (1, $p=0.00$) were significantly higher after the program. Scores on knowledge related to healthy behavior ($5\% \pm 3\%$, $p=0.08$) and skills related to sustainable behavior (0.16 ± 0.10 , $p=0.10$) after the program approached statistical significance. No notable differences were observed regarding the other outcome measures.

Conclusion: This study represents a valuable first step in evaluating the effects of the Food Challenge for adolescents in vocational and practical secondary education. The results indicated modest positive changes in physical activity and in several determinants related mainly to sustainable eating behaviors. Future research, ideally with a larger sample and a control group, is needed to further examine the effectiveness of the Food Challenge and other nutrition education programs, particularly for adolescents in more practical educational tracks.

I-P-G.33

Feeding Practices across Contexts: Fifteen Years of the Feeding Practices and Structure Questionnaire (FPSQ)

E. Jansen¹

¹Region Hovedstadens Psychiatry, Center for Eating and Feeding Disorders Research (CEDaR), Ballerup, Denmark

Purpose: Over the past 25 years, numerous parental food parenting measures have been developed. Some have been extensively tested and used in many different samples, while others were developed for study-specific purposes and seldom reused. The initial version of the Feeding Practices and Structure Questionnaire (FPSQ) was developed and validated 15 years ago in Australia and later extended with two additional developmentally appropriate versions. It was one of the first measures to assess structure-related feeding practices, in addition to the commonly measured coercive or non-responsive practices associated with childhood obesity. This presentation reflects on the evolution and usage of and issues with the FPSQ, with relevance to other feeding questionnaires.

Methods: FPSQ use across countries, languages and samples is summarized, based on records of requests from prospective users and systematic literature review. Issues arising from translation, adaptation, and implementation, particularly in recent Scandinavian applications, are also examined.

Results: The FPSQ has been used in 25 countries, with potential translation into 23 languages other than English. Validation studies include samples from Vietnam, Turkey and Scandinavia, as well as some specifically focused on samples of fathers. The FPSQ has been employed to evaluate intervention effectiveness (e.g., PICNIC, Fussy Eating Rescue), as content guide for qualitative research, and its scores utilized for targeted nutrition education. Translation work revealed cross-cultural comprehension challenges (e.g., terms such as being firm or upset in Vietnam), while Danish and Swedish adaptations required clarifying "(favourite) foods" to encompass snacks and meals (e.g., sweets or a dish of spaghetti). Internal reliability for structure-related feeding practices was occasionally lower than for

G. CHILDREN AND FAMILIES

non-responsive practices.

Conclusion: The FPSQ is widely used, validated across multiple contexts and including fathers, and demonstrates (longitudinal) measurement invariance. Its age-appropriate versions allow assessment of non-responsive and structure-related feeding practices from infancy to later childhood. Ongoing cultural adaptation and psychometric testing remain essential to ensure conceptual and linguistic equivalence across contexts, offering valuable insights for the continued refinement of this and other food parenting measurement tools.

³Windesheim University of Applied Sciences, Lectorate Human Movement, Health and Well-being, Zwolle, Netherlands,

⁴University of Groningen, University Medical Center Groningen, University Center of Psychiatry, Groningen, Netherlands

Purpose: Motor challenges, such as balance are a relevant topic in children with autism spectrum disorders (ASD). These motor challenges may affect more developmental areas, causing 'double trouble'. This study aimed to investigate whether the lower quality of motor skills also extends to water-related balance skills. These skills are crucial for learning to swim, ensuring safety in the water, and participating in aquatic sports and leisure activities. Balance control is essential to maintain a stable position and feel secure in the aquatic environment.

Methods: In this cross-sectional study, we compare land- and water-related balance skills of children with and without ASD in the 3th lesson of their swimming education. Participants were recruited from commercial swim class providers, swim clubs and through special education school swim programs. A sample of children (n=106) between 5 and 10 years old with ASD (n=26) and without ASD (n=80), have been assessed for their land-related balance skills with the Movement ABC-2 and for the water-related balance skills with the Water Orientation Test for ASD (Wot-ASD). The data were analysed with the Mann-Whitney U tests and regression analyses.

Results: Descriptive statistics indicate differences in age and gender distribution between the groups. The mean age of children with ASD is 7,6 years (sd 1,50), the mean age of TD children is 6,1 (sd 1,57). The division between boys and girls in the ASD group is 22:4, and in the TD group, 40:40

On total balance, dynamic balance and static balance, significant differences were found, respectively, α is .001, .001 and .018 in favour of the TD group. No significant differences were found on any of the Wot-ASD subscales or total scale. The correlation coefficient R for land-related balance and the total Wot-ass scale is 0.55 for the whole group, 0.66 for the TD group, and 0.159 for the ASD group.

Conclusion: Despite the significant differences in land-related balance, we may cautiously assume that this has only a small effect on learning aquatic skills in children with ASD as they adapt as effectively to the properties of the water as TD children at a younger age.

I-P-G.35

Examining Parental-child Associations in Physical Activity and Fitness: A Mediation Analysis of a 12-week Multicomponent Intervention

F. Rodríguez-Rodríguez¹, G. Salinas-Gallardo², C. Cristi-Montero¹, F.J. Huertas-Delgado³, P. Campos-Garzón⁴, X. Palma-Leal⁵, S. Hernández-Jaña¹

¹Pontificia Universidad Católica de Valparaíso, IRyS Group, School of Physical Education, Viña del Mar, Chile, ²Universidad de Playa Ancha, Physical Activity Science Observatory (OCAF), Department of Physical Activity Science, Valparaíso, Chile,

³University of Granada, Teacher Training Centre La Inmaculada, Granada, Spain, ⁴Karolinska Institutet, Department of Global Public Health, Stockholm, Sweden, ⁵Pontificia Universidad Católica de Valparaíso, School of Physical Education, Viña del Mar, Chile

Purpose: To determine the effect of a multicomponent intervention on the moderate-to-vigorous physical activity (MVPA) of parents and their children; secondly, to examine the change in physical fitness (PF) as a result of the intervention; thirdly, to explore how the intervention modifies the time when children's MVPA takes place by examining changes in their parents' MVPA.

Methods: Participants were 68 fathers or mothers (age=41.0 [IQR:38.0,45.0]) and 68 children (age=11.0 [IQR:10.0,11.0]).

G. CHILDREN AND FAMILIES

These parent-child dyads were volunteers from two private and one public school, intentionally allocated to control and intervention groups. Both groups completed questionnaires about MVPA and PF. The 12-week multicomponent intervention included educational infographics and videos highlighting the health benefits of regular physical activity, which were sent every Monday to parents via email and WhatsApp. On Fridays, parents received messages with suggestions for engaging in physical activities during the weekend. In addition, three face-to-face sessions were conducted with parents and children. The analysis was adjusted by age, sex and school. The comparison was made with the Wilcoxon rank sum test, and statistical significance was set at $p < 0.05$. All analyses were performed using “tidyverse” and “gtsummary” packages, and the “PROCESS” macro in R Studio for mediation analysis.

Results: Only general PF showed a statistically significant difference ($p = 0.030$) over time and between the delta values of the intervention and control groups. The intervention improved parents’ MVPA and increased children’s MVPA out-of-school ($p = 0.038$) and on weekends ($p = 0.024$). In mediation analysis, no direct or indirect effects were found in any of the proposed models, except for a significant association between the change in MVPA of parents and the change in MVPA of children. Specifically, the change in parents’ MVPA was inversely associated with in-school MVPA in children ($\beta: 0.01$; 95%CI: -0.01 – -0.00), while it was positively associated with out-of-school and weekend MVPA in children ($\beta: 0.04$; 95%CI: 0.00 – 0.04).

Conclusion: Intervention improved parents’ PF and increased children’s MVPA out of school and on weekends. These findings underscore the complex interplay between parental engagement and children’s physical activity, suggesting that even without direct mediation, parents’ participation in interventions can create meaningful benefits for their children’s active behaviours.

I-P-G.36

A Pilot Randomized Controlled Trial of a Pediatrician’s Referral to Summer Camp to Treat Obesity in Underserved Children: Study Protocol for the Summer CAMPs Trial

K. Brazendale¹, S. Gurnurkar², S. Quelly¹, V. Loerzel¹, D. Hahs-Vaughn¹, M. Beets³, G. Turner-McGrievy³

¹University of Central Florida, Orlando, United States, ²Nemours Children’s Hospital, Orlando, United States, ³University of South Carolina, Columbia, United States

Purpose: Children from low-income households and who are overweight or obese (OWOB) are at an increased risk of accelerated weight gain during summer months compared to peers. Current behavioral interventions and clinical practices to treat children with OWOB lack the necessary intensity, incorporate multi-component interventions that are difficult to deliver consistently; fail to address barriers such as cost, and are not implemented during a critical period for weight gain (summer). This study examines the feasibility, acceptability, and preliminary effectiveness of a pediatrician’s referral for low-income children with OWOB to attend summer day camps free of charge.

Methods: This US-based pilot randomized clinical trial will enroll 80 children (eligibility criteria: OWOB status, 5-11 years old, Medicaid-insured) who attend three pediatric endocrine clinics. Participants will be randomized to either a pediatric voucher referral (PVR) group ($n = 40$) from their endocrinologist to attend an 8-week summer camp free-of-charge, or a standard care control group ($n = 40$). Outcomes include: 1) feasibility (PVR delivery) and acceptability (PVR uptake), 2) changes in zBMI and %bodyfat during summer (PVR vs. standard care groups), and obesogenic behaviors (physical activity, sleep, screen time, and diet) differences between PVR and standard care groups, and 3) a qualitative exploration with children, parents, and clinic and camp providers of facilitators/barriers of participating in the intervention and challenges facing all families in relation to weight management during summer.

Results: This study is currently in the recruitment phase. Descriptive statistics will summarize feasibility and acceptability outcomes (*recruitment, adherence, data collection quality, intervention acceptability and fidelity*). Multilevel growth models will evaluate differences in slopes between the PVR and standard care for zBMI and %Bodyfat (Δ summer). Mixed-effects models will examine differences in obesogenic behaviors between PVR and standard care groups. Inductive and deductive processes will be used for coding qualitative transcripts and analysis of themes.

Conclusion: This study has great potential to inform policies supporting subsidized access to local summer day camps for underserved children and families meeting health- and income-based criteria. This approach is highly scalable given the widespread presence of summer day camps and pediatric health centers in communities across the US -- and other countries potentially.

I-P-G.37

Greater Home-specific Stress Is Positively Associated with Parents' Automatic Smartphone Use

K. Bowen¹, A. Rebar¹, J. Culverhouse¹, O. Finnegan¹, M. Bastyr¹, G. Randolph¹, M. Restino¹, J. White¹, N. Niako¹, A. Holmes¹, M. Beets¹, G. Weaver¹, S. Burkart¹, E. Adams¹, B. Armstrong¹

¹University of South Carolina, Arnold School of Public Health, Columbia, United States

Purpose: Screen use often becomes habitual under stress because it is constantly prompted by situational cues, is immediately rewarding, and can be cognitively undemanding, making it an efficient default when parents' mental bandwidth is reduced. Under stress, behavior shifts from goal-directed control to automatic responses, yet it remains unclear what type of stress is associated with automatic phone use in parents. This study investigates whether automatic phone use is associated with general perceived stress, or, more specifically, with context-dependent cues such as parental demands or environmental unpredictability (e.g., household chaos). We examined whether different types of stress differentially predict automatic smartphone use among parents with young children.

Methods: Parents of preschool-aged children ($n = 252$; 96% female, 69.4% White, mean age 36.0 ± 5.41 years) reported automatic phone use (Self-Report Behavioral Automaticity Index [SRBAI]), household chaos (Confusion, Hubbub, and Order Scale [CHAOS]), and general perceived stress (Perceived Stress Scale [PSS]). Home-specific stress was assessed via a 14-day EMA of stress arising from home demands, averaged across days. Hierarchical regression analyses were conducted to examine the associations of general perceived stress, home stress, and household chaos predicting automatic phone use. Covariates included parent sex, age, education, and income-to-poverty ratio.

Results: Greater home-specific stress significantly predicted greater automatic phone use ($B = 0.84$, 95% CI [0.11–1.58]). In contrast, neither household chaos ($B = 0.02$, 95% CI [0.00–0.05]) nor general perceived stress ($B = 0.01$, 95% CI [–0.03–0.04]) were associated with habitual automatic phone use after accounting for demographic factors. The model explained approximately 10% of the variance in habitual automatic phone use.

Conclusion: These results highlight the unique association between homespecific stress and parents' automatic smartphone use, suggesting that situational demands within the parenting environment may serve as cues for habitual screen behaviors. Stressors within the parenting environment may be particularly relevant for understanding automatic screen habits. Given the cross-sectional design, longitudinal assessments are needed to clarify the directionality of the relationship between home-specific stress and automatic phone use, and to examine how these screen time habits evolve over time.

I-P-G.38

Secular Trends in Accelerometer-derived Movement Behaviour Compositions among Czech Adolescents: Repeated Cross-sectional Analyses

D. Janda¹, J. Dygrýn¹, L. Rubín², F. Chmelík¹, T. Juřicová¹, A. Gába¹

¹Palacký University Olomouc, Olomouc, Czech Republic, ²Technical University of Liberec, Liberec, Czech Republic

Purpose: Movement behaviours (MB) are increasingly recognised as interdependent determinants of adolescent health. However, recent evidence on trends in 24-h MB suggests a decline in physical activity (PA) and an increase in sedentary behaviour (SB) compared with the pre-COVID-19 period. This study examined trends in the MB composition consisting of physical activity (PA), sedentary behaviour (SB), and sleep among adolescents.

Methods: Repeated cross-sectional data were collected between 2018 and 2025 (excluding 2020 and 2021) from a sample of 1,685 adolescents aged 10–18 years. Twenty-four-hour MB, including moderate-to-vigorous physical activity (MVPA), light physical activity (LPA), SB, and sleep duration, were assessed using accelerometers. Daily time-use compositions were analysed using a compositional data analysis approach. Temporal trends were examined using mixed-effects regression models, with data collection categorised into three periods (2018–2019, 2022–2023, 2024–2025) and 24-h MB expressed as a set of isometric log-ratios. Analyses were stratified by age (10–14 years and 15–18 years) and sex. Estimates of 24-h MB are presented as bootstrapped 95% confidence intervals (CI). Differences in sex and age distribution across observed periods were evaluated using the chi-squared test.

Results: There were no differences in the proportion of sex across the observed periods ($p > 0.5$). The sample included a higher proportion of older adolescents (15–18 years) in the 2024–2025 period compared with the other periods ($p < 0.02$). After adjustment for age and sex, stable trends in MB compositions were observed across the three periods. For the whole sample across all periods, estimated MVPA averaged 34.4–49.8 minutes, LPA 247.5–284.3 minutes, SB

G. CHILDREN AND FAMILIES

628.1–668.1 minutes, and sleep 467.7–502.6 minutes. Significant differences between age groups and sexes were observed in MB compositions.

Conclusion: Accelerometer-derived data analysed using compositional methods indicate stable secular trends in time-use compositions among adolescents from 2018 to 2025. These findings suggest that observed declines in MVPA and increases in SB during COVID-19 may reflect short-term disruptions rather than sustained changes in underlying time-use patterns. Continued surveillance using objective measures is essential to accurately monitor MB and inform population-level intervention

I-P-G.39

Health and Fitness of Children with Dyslexia during Summer versus School Months: A Longitudinal Study

K. Brazendale¹, T. Glatz¹, C. Shirley¹, M. Makanji¹, S. Molina¹, K. Kiely²

¹University of Central Florida, Health Sciences, Orlando, United States, ²University of South Carolina, Exercise Science, Columbia, United States

Purpose: Children with dyslexia often face unique challenges that extend beyond academic performance, such as motor deficits (e.g., poor balance, coordination) that may reduce enjoyment, confidence, and participation in physical activity. The structured days hypothesis posits that the structured school year promotes healthier behaviors (increased physical activity) compared to less-structured periods, such as summer months. During summer, several studies in neurotypical children have shown accelerated weight-gain and cardiorespiratory fitness (CRF) loss occurs in neurotypical children, yet, whether this finding holds true in neurodiverse children – such as children with dyslexia – is less understood. The purpose of this study was to compare changes in weight-related and fitness outcomes among children with dyslexia during summer versus school months.

Methods: Participants were recruited from a specialized school for children with dyslexia to participate in periodic anthropometric assessments (Pre-summer; May, Post-summer/Pre-school; August, and Post-school; December 2025). Anthropometric data (height, weight, and percent body fat (%BF)) were collected using a Tanita DC-430U bioelectrical impedance scale. CRF was assessed using the Progressive Aerobic Cardiovascular Endurance Run (PACER). All measurements were administered in school by research assistants during physical education. Paired t-tests were used to evaluate summer and school changes (Δ). All analyses were conducted in Stata (v16.1).

Results: Eighteen children with dyslexia (mean age 10.6 years $\pm$ 2.0, 55% male, 78% normal weight) participated in pre/post summer (~102 days apart) and pre/post school (~112 days apart) measures. Statistically significant changes were not observed for zBMI or %body fat during summer months compared to school months. PACER laps decreased over summer (Mean Δ pre-to-post summer = -11.39 laps; $t(17) = 4.49$, $p < 0.01$) compared to school (Mean Δ pre-to-post school = +3.5 laps; $t(17) = 1.98$, $p = 0.06$), representing a statistically significant Δ in CRF during summer months compared to school months (Mean $\Delta = 14.9$ laps; $t(17) = 4.72$, $p < 0.01$).

Conclusion: Preliminary findings indicate physical fitness declines over summer compared to school months in children with dyslexia. These initial data highlight the need for targeted interventions during out-of-school periods to maintain physical activity and CRF in vulnerable populations, such as children with dyslexia.

I-P-G.40

School Breakfast Initiatives Associated with Increased Participation

M. Curnutte¹

¹The Pennsylvania State University, Nutritional Sciences, State College, United States

Purpose: School meals are critical to children's health, as ~30 million children participate in school meals and children consume up to 50% of their caloric intake at school. School breakfast is associated with improved health and academic outcomes. To increase participation, schools have implemented innovative strategies, such as adding smoothies, adding equipment to offer more hot or cold food items, or increasing marketing for school breakfast. This study examines whether new strategies are associated with changes in participation rates.

Methods: A cross-sectional analysis included 84 Pennsylvania schools participating in a statewide initiative that provided funding to implement new breakfast strategies. Analysis of variance found differences in mean breakfast participation rates across initiatives. Descriptive analyses assessed identified barriers.

Results: Adding or expanding an alternative serving strategy, such as breakfast after the bell or grab-and-go breakfast,

G. CHILDREN AND FAMILIES

was associated with a 1.66% increase in participation, which would equate to an additional ~28,220 students across Pennsylvania (PA). Adding equipment to serve more hot food, increasing hot food options, and adding cold food items were associated with participation increases compared to schools that did not implement these strategies (0.35% or ~5,950 students across PA, 0.87% or ~14,790 students, and 1.10% or ~18,700 students, respectively). Adding other equipment to expand food offerings, adding smoothies, and increasing breakfast marketing were not associated with increased participation. The most reported barriers were staffing shortages (50.6%), delays in receiving equipment/supplies (45.1%), and limited time for breakfast (35.2%). Notably, the least common barrier was resistance from school administrators (10.5%). None of the observed differences reached statistical significance.

Conclusion: Modest changes in participation could translate to substantial additional student participation. The lack of statistical significance may be attributable to a small sample size. Alternative serving strategies and expanded food options, including the equipment needed, could increase student breakfast participation. Addressing staffing and supply challenges could enhance efforts. Implementing targeted breakfast strategies may be a practical approach for schools to increase participation and support student health and academic success. Future research could use a larger sample of schools to accurately test for statistical significance.

I-P-G.41

Validation of the Ghanaian Version of the Global Adolescent and Child Physical Activity Questionnaire (GAC-PAQ): A Pilot Study

P.K. Akwaboah¹, R. Larouche¹, R. Ocansey²

¹University of Lethbridge, Faculty of Health Sciences, Lethbridge, Alberta, Canada, ²University of Education, Winneba, Ghana

Purpose: Physical activity surveillance among children and adolescents in low- and middle-income countries (LMICs) is constrained by limited culturally validated tools and the omission of key activity domains (e.g., chores and active play) in existing questionnaires. To address this gap, the app-based Global Adolescent and Child Physical Activity Questionnaire (GAC-PAQ) is currently being validated in 17 countries. This pilot study assessed the feasibility and acceptability of the app in Ghana in preparation for the main validation study.

Methods: Thirty-three child–parent dyads (children aged 8–17 years) were recruited from two schools in the Effutu Municipality, Winneba, Ghana. Participants completed the English language app-based GAC-PAQ with minimal research assistant support. Feasibility and acceptability outcomes included completion rate, completion time, post-survey ratings, and participant comments. Satisfaction was assessed with a 5-point scale ranging from very dissatisfied to very satisfied. Descriptive statistics summarize sociodemographic and outcome variables.

Results: The mean age of participating children and adolescents was 12.2 ± 2.7 years (54% female; 50% aged 8–11 years; 55% rural). Sixty-five participants completed the survey (100% adults, 100% children, 94% adolescents), yielding an overall completion rate of 99%. Mean completion time was 14 minutes. Overall, 92% of respondents reported being satisfied or very satisfied with the app. Seventeen participants provided in-app comments, with most describing the app as easy to use and reflective of children's routine activities. No negative usability concerns were reported.

Conclusion: The app-based GAC-PAQ demonstrated high acceptability and feasible completion time among child–parent dyads in Ghana, supporting progression to large-scale cross-sectional validation and broader implementation in LMIC surveillance contexts.

I-P-G.42

Examining the Relationship between Parental Eating Behaviours and Parental Feeding Practices and Styles: A Systematic Review

C.C. Bouchaud^{1,2}, P. Varshney¹, Y. Han¹, T.R. Cohen^{1,2}

¹The University of British Columbia, Faculty of Land and Food Systems; Food, Nutrition and Health, Vancouver, Canada,

²British Columbia Children's Hospital Research Institute, Healthy Starts, Vancouver, Canada

Purpose: Parental feeding practices and styles can have lasting impact on the development of eating behaviours in children. However, the origins of parental feeding practices are not fully understood. We hypothesize that parental feeding practices and styles are informed in part by the parent's own eating behaviours. Therefore, the objective of this systematic review was to explore how eating behaviours of parents of children and adolescents are associated to their feeding styles and practices.

G. CHILDREN AND FAMILIES

Methods: This systematic review (PROSPERO Registration: CRD42024602542) explores the concept of parental eating behaviours, measured using questionnaires such as the Adult Eating Behaviour Questionnaire, Intuitive Eating Scale 2 or the Three-Factor Eating Questionnaire, and how they may be linked to parental feeding practices and styles, measured using tools such as the Child Feeding Questionnaire or Comprehensive Feeding Practices Questionnaire or observational methods. Searches were conducted in Medline, PubMed, Web of Science and PsycINFO. Observational studies (e.g., cross-sectional studies, cohort studies) or qualitative studies published in English between 2000 and 2025 were considered examining generally healthy parents and their children between 0 and 18 years old. All articles were screened using Covidence software by two researchers. Quality appraisal was conducted using the JBI Checklist for Analytical Cross Sectional Studies.

Results: Database searches yielded 5,736 records; 41 articles were included in this review. Articles explored notably parental eating behaviours such as emotional eating, dietary restraint and external eating found positive associations between these behaviours and parental feeding practices such as dietary restriction, instrumental eating and pressure to eat. Overall, studies mainly included mothers, were conducted in high income, western countries and focused on maladaptive eating behaviours and coercive feeding practices.

Conclusion: This review has the potential to improve our understanding of how parental feeding practices are linked to the parent's own eating behaviours. Future research should investigate eating behaviours and feeding practices of fathers as well as more positive eating behaviours and parental feeding practices. The results of this review could impact how family-based eating behaviour change interventions are developed, taking into consideration the eating behaviours of the parent to address how they feed their children.

I-P-G.43

Capturing Healthy Growth: A Photovoice Study of Professional Perspectives on Multilevel Influences on Nutrition and Physical Activity for Children across Texas

J. Yudkin^{1,2}, N. Parthasarathy², B. Smith¹, C. Crudo Blackburn³

¹Texas A&M University, Health Behavior, College Station, United States, ²University of Texas Health Science at Houston, Center for Health Promotion and Prevention Research, Houston, United States, ³Texas A&M University, Health Policy and Management, College Station, United States

Purpose: Childhood high weight has been labeled a pandemic and represents a multifactorial, multilevel public health challenge deeply connected to local context. While research has identified risk factors and effective interventions, the global burden continues to grow, disproportionately affecting vulnerable populations—revealing a disconnect between available evidence and contemporary contextual realities. Despite research on community experiences, little is known about how public health (PH) professionals perceive broader social and environmental influences on obesity prevention. Guided by implementation science, the Local Engagement through Narratives and Snapshots (LENS) Study used photovoice to identify community-level barriers and facilitators for helping children maintain healthy growth patterns. This study innovatively applies photovoice within a professional context, enabling participants to critically examine childhood high weight prevention influences informed by field experience.

Methods: Co-designed with community stakeholders and organized by the socioecological model (SEM), the LENS study conducted two photovoice sessions with 13 PH professionals at a Texas public health gathering in Fall 2025. Participants submitted images related to healthy living and engaged in hour-long focus groups facilitated by the SHOWeD framework. Sessions were audio-recorded and transcribed verbatim. Two researchers conducted thematic analysis combining inductive coding with deductive SEM mapping.

Results: Participants were predominantly (61.5%) employed in state/local government health organizations. At the community level, conducive built and social environments—including parks, playgrounds, beautified trails, health promotion messaging, and social connection—were identified as facilitators, while food deserts, limited transportation, and unhealthy community norms emerged as barriers. At the organizational level, healthy food menus and behavior-change incentives facilitated prevention. At the interpersonal level, influences had dual effects: intergenerational learning and coworker modeling fostered healthy behaviors, whereas family pressure, cultural norms, and unhealthy home environments presented barriers. At the individual level, knowledge, motivation, and cultural preferences enabled healthy living, while stigma, personal preferences, and skill deficits acted as barriers. Findings underscored the interconnected nature of these multilevel factors, demonstrating that influences on obesity prevention rarely occur in isolation.

Conclusion: These findings provide PH professionals with actionable leverage points within communities and relationships to design targeted, multilevel behavior change strategies for healthy child growth and obesity prevention.

I-P-G.44

Early Childhood Home Food Environment Is Linked to Fruit and Vegetable Consumption in Pre-adolescence: A Longitudinal Study

N. Serasinghe¹, C. Ray^{2,1}, R. Lehto^{2,1}, J. Kailaheimo-Björkqvist^{2,3}, M. Maukonen^{2,4}, R. Pajulahti¹, H. Launistola^{2,5}, T. Sarvanne¹, H. Imran¹, E. Roos^{2,6,7}, M. Erkkola¹, H. Vepsäläinen¹

¹University of Helsinki, Department of Food and Nutrition, Helsinki, Finland, ²Folkhälsan Research Center, Helsinki, Finland, ³Institute of Applied Health Sciences, University of Aberdeen, Aberdeen, United Kingdom, ⁴Finnish Institute for Health and Welfare, Helsinki, Finland, ⁵University of Helsinki, Faculty of Medicine, Helsinki, Finland, ⁶University of Helsinki, Department of Public Health, Helsinki, Finland, ⁷Uppsala University, Department of Food Studies, Nutrition and Dietetics, Uppsala, Sweden

Purpose: The early childhood home food environment, including food availability, parental role-modelling, and parental self-efficacy, plays a primary role in shaping children's food consumption, which may persist into later life. We examined whether the early childhood home food environment is associated with fruit and vegetable consumption in pre-adolescence.

Methods: We used longitudinal data from 207 children participating in both the baseline (2017; aged 3-6 years) and the 6-year follow-up (2023-2024; aged 9-12 years) of the DAGIS Salo study in Finland. At baseline, parents completed a questionnaire assessing the family's socioeconomic status (as parental educational level and household relative income), the child's age and gender, the availability of fruits and vegetables at home, parental role-modelling of fruit and vegetable consumption, and parents' self-efficacy in their ability to get the child to consume an adequate amount of fruits and vegetables. At follow-up, children completed a food frequency questionnaire on their fruit and vegetable consumption during the preceding week, with assistance from a parent. Associations between aspects of the early childhood home food environment and children's fruit and vegetable consumption during pre-adolescence were assessed using linear regression models adjusted for the child's age, gender, and family's socioeconomic status.

Results: In the regression model adjusted for the child's age, gender, and family's socioeconomic status, higher fruit and vegetable availability at home ($B=3.7$, 95% CI 1.6–6.0, $p=0.002$) and higher parental self-efficacy ($B=1.6$, 95% CI 0.2–3.2, $p=0.03$) in early childhood were significantly associated with more frequent fruit and vegetable consumption in pre-adolescence.

Conclusion: Improving home availability of fruits and vegetables and supporting the boosting of parental self-efficacy in getting their children to consume adequate amounts of fruits and vegetables during early childhood may enhance children's fruit and vegetable consumption in the long term, regardless of the family's socioeconomic status. These factors should therefore be targeted in future health promotion policies and interventions.

I-P-G.45

Schools Shape Who Moves, Where and How: Child-centred Realist Systems Mapping of Gendered Movement Inequalities in Scotland

R. Sutton¹, A. Martin², J. Stokes¹, O. Traynor¹, P. McCrorie³, B. Rigby⁴

¹University of Glasgow, School of Health and Wellbeing, Glasgow, United Kingdom, ²Austrian National Public Health Institute, Austrian National Public Health Institute, Vienna, Austria, ³University of Exeter, Public Health and Sport Sciences, Exeter, United Kingdom, ⁴Newcastle University, Population Health Sciences Institute, Newcastle, United Kingdom

Purpose: Qualitative research on schoolbased physical activity (PA) often lists independent barriers and facilitators without explaining how everyday practices interact to (re)produce movement inequalities. Working with young children also raises questions about capturing this complexity in childcentred ways. This study used ChildCentred Realist Systems Mapping (CCRSM) to examine how primary school children experience movement and explain gendered inequalities in who moves and where.

Methods: A qualitative systems study was conducted with 24 pupils (aged 5–11 years) in two Scottish primary schools, using walking interviews ($n=22$) and drawandtell activities ($n=14$) to generate childcentred accounts of movement and how routines, social norms and school spaces interrelate. Data were analysed using a realistinformed thematic approach to identify causal mechanisms that shape movement patterns. Insights were first developed as context–mechanism–outcome (CMO) configurations, then translated into causal loop diagrams that visualised feedback processes and interconnections in the PA system.

Results: Children described interconnected themes showing how routines, gendered expectations and experiences

G. CHILDREN AND FAMILIES

of (un)belonging shape who moves where and how. “Movement wanted, movement rationed” captured desires to be active alongside tightly controlled opportunities, with brief “up on your feet” tasks remembered as calming and supporting learning. “Real sport is football” showed boys routed into visible, wellresourced football, while girls’ appetite for competition was pushed into lowerstatus, more fragile options. “Feeling safe to join in” highlighted how anticipated judgement and perceived competence shaped girls’ use of active spaces. Through iterative refinement, we developed four overarching and multiple supporting finegrained CMOs, and then causal loop diagrams, revealing interconnected, reinforcing feedback loops (n=5) that help explain how the gender gap in PA is reproduced over time.

Conclusion: CCRSM made visible the contexts and mechanisms through which schools (re)produce gendered hierarchies of movement, positioning boys’ activity as central while constraining and obscuring girls’ movement. As the first participatory CCRSM study in Scotland, this childcentred systems mapping connects children’s lived experiences to wholeschool practices and policy decisions, offering ways to plan changes that disrupt gendered patterns of whose movement is visible, valued and supported.

I-P-G.46

Dad Central: Evaluating the Usability and Acceptability of a Digital Father-focused Child Feeding Resource for Home Visiting Programs

J. Zeldman¹, N. Timothee², E. Lammens³, S. Ramirez³, K. Shelnutt¹, D. Jake-Schoffman², D. Varma⁴, A. Mobley²

¹University of Florida, Institute of Food and Agricultural Sciences Extension, Gainesville, United States, ²University of Florida, Department of Health Education and Behavior, Gainesville, United States, ³University of Florida, Gainesville, United States, ⁴University of Florida, Department of Epidemiology, Gainesville, United States

Purpose: Fathers play a critical role in shaping early childhood feeding behaviors yet are often underrepresented in early intervention programs, including home visiting programs (HVPs). Intentionally tailoring resources for fathers within HVPs offers a promising avenue to engage them in promoting healthy feeding practices and preventing childhood obesity. Using a community-engaged approach, a novel digital child feeding resource, Dad Central, was created for fathers. This study evaluated the usability and acceptability of Dad Central among fathers involved with HVPs.

Methods: A concurrent mixed methods design was utilized. Fathers (n=17) of young children, either currently or previously enrolled in HVPs or employed as fatherhood coaches, were recruited using purposive sampling and completed a three-part usability protocol. The protocol included an informational session and tutorial of Dad Central, a one-week usability period, and a follow-up, virtual semi-structured interview informed by the Technology Acceptance Model and Theory of Planned Behavior. Fathers also completed the validated mHealth App Usability Questionnaire (MAUQ; 1=low, 7=high). Quantitative data were analyzed using descriptive statistics, and interviews were audio-recorded, deidentified, transcribed, and analyzed using inductive thematic analysis.

Results: Overall, MAUQ scores indicated high perceived usability of Dad Central (6.35±0.56), with ease of use rated highest (6.55±0.48), followed by interface and satisfaction (6.31±0.59), and usefulness (6.20±0.86). For acceptability, participants reported they would use Dad Central again (6.41±0.51), were satisfied overall (6.47±0.51), and agreed it was an appropriate way to receive child feeding information (6.29±0.85). Qualitative insights supported these findings, with fathers describing the platform as intuitive, user-friendly, and engaging, with appealing branding and useful content and features. Suggestions for improvement include adding more visual aids and vibrant colors, consolidating or differentiating overlapping content, expanding topics and features, and increasing accessibility.

Conclusion: Dad Central was perceived as highly usable and acceptable by fathers of young children participating in HVPs. Findings support further refinement and larger-scale testing to evaluate effectiveness and highlight Dad Central’s potential as a model for tailoring digital child feeding resources in other early childhood intervention settings.

I-P-G.47

Cultural Adaptation and Content Validation of the Family Nutrition and Physical Activity (FNPA) Screening Tool for Tamil-speaking Families

J. Joseph¹, J. Rachel², J. Yudkin³

¹Texas A&M University, Environmental and Occupational Health, College Station, United States, ²Aarupadai Veedu Medical College and Hospital, Puducherry, Department Of Community Medicine, Puducherry, India, ³Texas A&M University, Health Behavior, College Station, United States

G. CHILDREN AND FAMILIES

Purpose: Unhealthy dietary patterns and insufficient physical activity in childhood are major contributors to adverse health outcomes across the life course. Global evidence indicates that one in five children or adolescents experience excess adiposity, with more than 80% residing in low- and middle-income countries undergoing rapid nutrition and lifestyle transitions. In India, southern regions such as Puducherry and Tamil Nadu report combined overweight and obesity prevalence exceeding 20% among certain school-aged populations, particularly in urban settings. These trends highlight the urgent need for culturally responsive tools to assess family-level nutrition and physical activity behaviors within Tamil-speaking communities. The Family Nutrition and Physical Activity (FNPA) screening tool is widely used internationally to evaluate home environments that support healthy behaviors; however, a validated Tamil version is not currently available. This study aimed to translate, culturally adapt, and evaluate the content validity of the FNPA for use among Tamil-speaking families.

Methods: A structured cross-cultural adaptation process was conducted in community clinics across Tamil speaking population. The original English FNPA was forward translated into Tamil by bilingual researchers and independently back translated into English to ensure conceptual equivalence. Ten experts in pediatrics and internal medicine evaluated content validity using structured rating forms; item-level and scale-level Content Validity Indices (I-CVI and S-CVI) were calculated. Cognitive interviews with 50 parents using verbal probing techniques assessed clarity and cultural relevance, with thematic analysis guiding revisions. The finalized Tamil FNPA was administered to 50 participants to evaluate internal consistency using Cronbach's alpha and item-total correlations.

Results: Expert ratings demonstrated strong content validity across items. Cognitive interviews confirmed overall comprehension and cultural appropriateness, with minor refinements for locally relevant terminology related to dietary practices, screen time, and physical activity. The Tamil FNPA showed good internal consistency (Cronbach's alpha = 0.83), with item-total correlations ranging from -0.06 to 0.85. All 20 items were retained.

Conclusion: The Tamil adaptation of the FNPA demonstrates strong content validity and cultural appropriateness for assessing family nutrition and physical activity behaviors in Tamil-speaking clinical populations. This culturally refined instrument provides a foundation for subsequent psychometric validation and broader implementation in community health settings.

I-P-G.48

Energy Balance-related Behaviors Trajectories among Latino Fathers and Youth

R. Francis¹, S. Alvarez de Davila², G. Hurtado Choque¹

¹University of Maryland, College Park, United States, ²University of Minnesota, Minneapolis, United States

Purpose: To evaluate the longitudinal effects of Padres Preparados, Jóvenes Saludables (Prepared Parents, Healthy Youth), an obesity-prevention program, on fathers' and adolescents' energy-balance-related behaviors.

Methods: Design: A randomized controlled trial. Setting: Community-based organizations in a US Midwestern city. Participants: Seventy-three father-adolescent dyads (intervention group: n = 38; delayed treatment control group: n = 35).

Intervention: Father-youth dyads attended eight in-person, 2.5-hour weekly educational sessions delivered by trained bilingual Latino educators. The intervention focused on healthy eating behaviors and physical activity and their importance

in leading a healthy lifestyle. During each session, parents and adolescents participated in skill-building activities related to meal preparation, physical activity, nutrition, and an active lifestyle. Caregivers also participated in activities to develop their parenting skills and improve their dietary and physical activity parenting practices, whereas youth education focused on healthy lifestyle behaviors. Variables Measured: Self-administered surveys to measure fathers' sugar-sweetened beverage (SSB) and fast food (FF) intakes and physical activity (PA) levels; 24-hour recall interviews to determine adolescents' SSB and FF intakes and self-administered surveys to assess their PA levels. Analysis: Mixed-effects models for repeated measures.

Results: This study aimed to examine fathers' and adolescents' consumption of sugar-sweetened beverages and fast food, and their physical activity levels, longitudinally from baseline to three months post-Padres intervention program. We found a statistically significant difference in fathers' SSB consumption (P=0.010) between the intervention and delayed-treatment control groups from T1 to T3. No significant differences in adolescents' SSB consumption were observed between the two groups over time. There were no significant results for either fathers' or adolescents' fast-food consumption or physical activity levels.

Conclusion: The program decreased fathers' SSB consumption. However, the program did not address other dietary behaviors among participants. Future research should focus on several key areas to build on the findings of this study.

G. CHILDREN AND FAMILIES

One important direction is to optimize the Padres Preparados, Jovenes Saludables' intervention by incorporating a physical activity component, such as the Familias Activas (Active Families) program. Adding structured physical activity sessions could enhance the intervention's overall effectiveness in promoting healthier lifestyles among fathers and adolescents.

I-P-G.49

Association between Children's Screen-based Device Use and Accelerometer-measured 24-h Movement Behaviours on Weekdays and Weekend Days in Rural Ontario, Canada

B. Bruner¹, C. Culotta¹, B. daCosta², B. Law¹

¹Nipissing University, School of Physical and Health Education, North Bay, Canada, ²McGill University, Department of Kinesiology and Physical Education, Montreal, Canada

Purpose: The pervasive use of screen-based devices has rapidly changed in a short period of time, with access occurring at younger ages. There is concern about how screen-based devices impact the movement behaviours of children and youth, particularly during their discretionary time, such as on weekends, as it promotes increased sedentary behaviour (SB) at the expense of health-enhancing behaviours such as sleep and physical activity (PA). The purpose of this study was to investigate associations between screen-based device use and movement behaviours, specifically sleep and sedentary behaviour, among elementary school children during weekend days.

Methods: Participants were 218 children (50.5% girls) ranging in age from 4 to 14 years ($M_{age} = 9.41 \pm 2.61$) from two schools in rural Ontario, Canada. Participants wore a GENEActiv accelerometer on their non-dominant wrist for 24 hr/day for 7 consecutive days. Data were filtered for 16 hours of wear-time per day, and the proportion of time spent on each behaviour per day was estimated using Hildebrand et al. (2016) cut-off points. Participants answered questions about their electronic device ownership and use of electronic devices before bed (within 30 minutes to 2 hours before bed). Independent samples t-tests were performed to determine group differences in the proportion of time spent on weekday and weekend activities (sleep, SB, LPA, and MVPA) between students who used or not use screen-based devices.

Results: Participants who did not use/own electronics had higher sleep proportion times on weekdays (.39 vs .37, $p < 0.01$) and weekends (.41 vs .38, $p < 0.01$), as well as lower SB on weekdays (.39 vs .43, $p < 0.01$) compared to students who use/own electronics. No significant differences were observed for PA.

Conclusion: The findings highlight the impact of screen-based device use on increasing SB and displacing sleep, given no observed differences in PA. Since sleep is important for health, learning and overall development, the results underscore the importance of enhancing awareness among parents/guardians and children about the importance of good sleep hygiene habits and intentionally managing screen use, particularly in the evening.

I-P-G.50

Persuasive Design for Feasible Nutrition Education in Primary Schools: Insights from Future Educational Professionals

J. Sikkens¹, V. van Stokkom², J. Heideman²

¹Inholland University of Applied Science, Health, Sport and Welfare, Haarlem, Netherlands, ²Inholland University of Applied Science, Agri, Food & Life Sciences, Haarlem, Netherlands

Purpose: Primary schools are important environments for supporting healthy eating behaviors, yet educators often struggle to select and implement suitable nutrition education tools. This study aimed to map available Dutch nutrition education tools and identify which persuasive design elements and feasibility conditions future educational professionals consider most relevant. The innovation lies in applying the Persuasive Systems Design model (Oinas-Kukkonen & Harjumaa, 2009) together with feasibility insights from experts and students training to become educational professionals.

Methods: A literature review identified existing Dutch nutrition education tools and relevant persuasive design elements. Eleven tools were selected using predefined criteria, including primary-school suitability, distinctiveness, theory-practice balance, time requirements and focus on food-related learning. Four semi-structured interviews with programme developers, educational designers and a public health professional validated the categorisation.

G. CHILDREN AND FAMILIES

Subsequently, four focus groups were held with 52 students enrolled in the Associate Degree programme Pedagogical Educational Professional (pre-service educational professionals working in primary education or childcare). Participants reviewed hypothetical cases representing different configurations of nutrition education tools. Transcripts and worksheets were thematically analysed, focusing on the perceived usefulness of persuasive design elements—practice, reduction (task simplification), social learning and simulation—and feasibility determinants such as time, workload, financial resources, space and parental involvement.

Results: Participants consistently preferred practice-oriented activities, such as cooking and school gardening. These were perceived to offer meaningful opportunities for practice, social learning and simulation. Participants expected such activities to support engagement and awareness, while recognising that no child outcomes were measured. Structural, repeating formats were viewed as more educationally valuable than one-off activities, yet weekly delivery was considered unrealistic. Monthly or quarterly integration was regarded as feasible. Major barriers included limited time, workload, budget constraints, logistical challenges and difficulties engaging parents. Perceived suitability did not differ across school types due to limited variation.

Conclusion: Effective nutrition education for primary schools should be practice-oriented, repeated but realistically scheduled, and designed using persuasive design elements such as practice, reduction, social learning and simulation. Feasibility depends primarily on time, resources and organisational support. These findings provide actionable guidance for developers and schools seeking to create feasible and meaningful nutrition education tools.

II-P-G.01

Integrative Interventions to Address Food Insecurity: Ideas From Professionals Working across Multiple Sectors of Hunger Relief

J. Berge¹, A. Diaz², B. Hillard²

¹University of Colorado, Anschutz Medical School, Family Medicine, Aurora, United States, ²University of Minnesota, Public Affairs, Minneapolis, United States

Purpose: Food insecurity is a critical public health problem that is associated with harmful health and wellbeing outcomes for children and adults. Research is needed to understand the role(s) of different sectors that could contribute to integrative solutions to mitigate food insecurity. The aim of this study was to identify potential integrative solutions to address food insecurity with professionals who work across multiple sectors with families experiencing food insecurity.

Methods: Interactive focus groups using principles from Human Centered Design were conducted with participants/professionals (n=47) working in research, health care, education, policy, faith-based, and hunger relief sectors in the Twin Cities area of Minnesota. Participants (age range=31-80 years; 60% women; 40% underrepresented in research) participated in one of ten virtual focus groups via zoom. Qualitative data collected from focus groups and Jamboards were analyzed using a hybrid deductive/inductive thematic approach to address three research questions.

Results: Fourteen overarching qualitative themes with thirteen subthemes were identified for three study research questions. For research question one, three main themes were found regarding what was currently happening in the hunger relief system including:

- (a) siloes with existing partnerships formed via referrals;
- (b) partnerships formed over time; and
- (c) looking for connections for more integration.

Four main themes were found for research question two related to what key components are necessary for a strong hunger relief system including:

- (a) choice and autonomy for participants;
- (b) education/skill;
- (c) stigma; and
- (d) basic needs first.

Seven main themes with multiple subthemes were found for research question three regarding integrative approaches to address food insecurity including:

- (a) creative solutions promoting collaboration that benefits individuals and families;
- (b) new systems/platforms for running programs;
- (c) policies;
- (d) food distribution/delivery systems;
- (e) fearless collaborations;
- (f) communication; and (g) intentional integration.

G. CHILDREN AND FAMILIES

Conclusion: This study identified key factors that may contribute to developing and implementing integrative solutions to improve food security among families such as creative solutions using faith-based sectors for implementation, breaking down siloes, leveraging current collaborations instead of reinventing the wheel, need for strong and flexible policy, and fearless collaboration.

II-P-G.03

PICNIC in Sweden: Pilot Phase Results to Adapt a Peer-education Child Feeding Intervention from Australia to Swedish Child Healthcare

K. Duncanson^{1,2}, A. Jörnvi³, S. Ask⁴, M. Högman³, E. Belestam Vikman³, R. Ball^{1,5}, M. Henström Engblom^{3,1}

¹University of Newcastle, College of Health, Medicine and Wellbeing, Newcastle, Australia, ²Hunter Medical Research Institute, Food and Nutrition Research Program, New Lambton Heights, Australia, ³Karolinska Institutet, Department of Medicine, Huddinge, Stockholm, Sweden, ⁴Sara Ask Produktion AB, Stockholm, Sweden, ⁵Mid North Coast Local Health District, Health Promotion, Port Macquarie, Australia

Purpose: Globally, child healthcare promotes healthy eating in families but lack evidence-based resources tailored for parents requiring additional child feeding support. The ‘PICNIC Sweden’ pilot study aimed to test the feasibility, acceptability, appropriateness, and perceived impact of the Australian peer-education child feeding program PICNIC with Swedish parents. This abstract focus on key learnings that will inform the next phase, where PICNIC will be further adapted and evaluated as a targeted, need-based support within Swedish child healthcare.

Methods: The mixed methods pilot study tested an adapted version of PICNIC with 47 parents of children aged 0-2 years. Parents attended a 2-hour dietitian-led online workshop and were invited to engage in a closed Facebook group for further child feeding guidance and peer-support. Data were collected through digital pre-and-post questionnaires (91% response rate) and semi-structured interviews (n=15; thematic analysis) after two months, with the data integrated and interpreted using a convergent parallel mixed-methods approach.

Results: Mean self-efficacy was 7.8±1.5 at baseline and 8.1±1.4 at follow-up. Online engagement varied, but 93% reported preference to continue in the closed Facebook group. More than half the parents had shared PICNIC information/advice with other parents (77%), friends (58%) and/or family (56%). Qualitative findings indicate the intervention was well received and met parents’ needs. Parents felt more confident and trusted their child’s abilities during mealtimes, valued the ‘safe space’ and sense of community PICNIC provided, and found reassurance from recognizing oneself in others’ situations. While in-person interaction with dietitian and peers was appreciated, parents also highlighted benefits of self-directed options. Involvement of both parents was desired but strategies to reach and engage more fathers remain unclear.

Conclusion: This pilot study showed high acceptability and appropriateness of the PICNIC intervention model among Swedish parents. While self-directed learning modules may improve access and scalability, our findings also highlight the value of providing opportunities for peer-support and shared learning. Next, co-design with parents and professionals will refine intervention content and adapt the mode of delivery to a more scalable format while preserving peer-support as a core component.

II-P-G.04

Influence of Dietary Habits, Screen Time, and Sleep on Anthropometric Variables, Physical Fitness, and Motor Competence in Preschool Children

A. Godoy¹, J. de Souza²

¹Universidad Autónoma de Chile, Grupo de Investigación en Educación Física, Salud y Calidad de Vida (EFISAL), Facultad de Educación, Temuco, Chile, ²Universidad Andres Bello, Facultad de Educación y Ciencias Sociales, Instituto del Deporte y Bienestar, Santiago de Chile, Chile

Purpose: This study examined the associations between dietary habits, screen time, and sleep with anthropometric indicators, physical fitness, and gross motor competence in preschool and early school children from Chile’s Araucanía Region. It was hypothesized that compliance with lifestyle recommendations would be positively associated with physical and motor outcomes.

Methods: A cross-sectional study was conducted with a non-probabilistic sample of 363 children aged 4–7 years from various communes in southern Chile. Anthropometric variables (weight, height, BMI, waist circumference), physical

G. CHILDREN AND FAMILIES

fitness (cardiorespiratory endurance, muscular strength, speed/agility), and gross motor competence (MABC-2) were assessed. Parents completed questionnaires on eating habits (Krecek Plus), screen time, and sleep duration. Compliance was categorized as follows: screen time <2 h/day, sleep ≥10 h/night, and eating habits classified as high, medium, or low according to Krecek Plus scoring. Group differences were analyzed by age and compliance level using Student's t-tests and ANOVA ($p < 0.05$, SPSS v.28).

Results: No significant differences were observed according to screen time compliance. Limited differences emerged for dietary habits, including height among 5-year-olds ($p = 0.039$) and jump performance among 6-year-olds ($p = 0.040$). Sleep compliance revealed more pronounced differences in height (4- and 6-year-olds, $p < 0.05$), handgrip strength (4 years, $p = 0.005$), and balance (4 years, $p < 0.05$). Associations were generally weak, likely influenced by parental reporting biases underestimating unhealthy behaviors.

Conclusion: Lifestyle factors showed minimal associations with anthropometric and functional outcomes, with sleep appearing as the most consistent predictor of favorable development. Interventions should emphasize healthy routines and incorporate objective assessments to overcome self-report limitations and support early child development in Chilean preschoolers.

II-P-G.05

Promoting Exclusive Breastfeeding to Reduce the Dual Burden of Malnutrition: Formative Research Insights from the Galápagos Islands, Ecuador

I. Headley¹, A. Thompson¹, S. Martin¹, M.B. Ocampo-Ordoñez², N. Villegas-Rodriguez³, L. Rocha³, L. Bookhart⁴, M. Kay⁵, H. Wasser¹

¹University of North Carolina at Chapel Hill, Nutrition, Chapel Hill, United States, ²Universidad San Francisco de Quito, Nutrición, Quito, Ecuador, ³University of North Carolina at Chapel Hill, School of Nursing, Chapel Hill, United States, ⁴University of North Carolina at Chapel Hill, Maternal and Child Health, Chapel Hill, United States, ⁵Wake Forest University, School of Medicine, Winston-Salem, United States

Purpose: Exclusive breastfeeding (EBF), a 'double duty action' that simultaneously protects children against under- and overnutrition and decreases maternal risk for non-communicable diseases, is not practiced by most women living in the Galapagos. To co-design an intervention to improve EBF, we used formative research methods to better understand EBF experiences in the islands.

Methods: We conducted semi-structured interviews among 20 mothers of infants <24 months, 6 family members, and 10 community stakeholders. Interviews were conducted in Spanish and audio recorded. Team-based rapid qualitative analysis (RQA) was used to summarize and interpret data. The first author listened to each recording and directly entered summaries into a structured matrix based on the interview guide. A second analyst reviewed the audio-recording or transcript to confirm or refine the initial summary. Themes were identified through analysis of the matrices. 'Member checks' were performed, whereby preliminary findings were shared with mothers to provide opportunity to validate, clarify, or expand initial themes.

Results: Mothers described insufficient milk, lack of confidence and local lactation support, separation from family living on the mainland, convenience of commercial milk formula (CMF), and unsupportive employers as key barriers. Although family members and health professionals expressed support for breastfeeding, there was a gap in understanding how early CMF introduction disrupts the biological process of lactation. Perception of available support differed among mothers and health professionals, with health professionals describing a lack of initiative among mothers and mothers feeling uncomfortable asking providers for advice due to lack of trust. To improve EBF, participants recommended using WhatsApp chats, incorporating social media, offering perinatal home visits centered on infant and maternal nutrition and mental health, involving family members, clarifying employer responsibilities to support breastfeeding, and creating a milk bank. They also identified trusted locals who could help create and deliver the program.

Conclusion: While breastfeeding is the norm in the Galapagos Islands, rates of EBF are low and may contribute to the dual burden of malnutrition. Mothers, family members, and community stakeholders identified modifiable barriers and proposed multiple opportunities for helping families practice EBF. These findings may be relevant in other Latin American or rural communities.

G. CHILDREN AND FAMILIES

II-P-G.06

The Impact of Food and Non-alcoholic Beverage Sponsorship and Marketing in the School Environment on Food Choices of School-going Children and Adolescents: A Scoping Review

L. du Plessis¹, K. Farmer¹, R. Beukes¹

¹Stellenbosch University, Global Health, Division of Human Nutrition, Cape Town, South Africa

Purpose: Globally, childhood obesity presents as a major public health challenge that is steadily on the increase. This is a result of, among other factors, children consuming excessive amounts of empty calories, specifically from foods high in saturated fats, refined sugar, and sodium, which may be exacerbated by targeted marketing and sponsorships. This scoping review aimed to investigate the prevalence of food and non-alcoholic beverage marketing in schools and to determine the impact marketing and sponsorship in the school environment has on the food choices of school-going children and adolescents. The objectives of the scoping review were to conduct a systematic search of available and relevant literature, identify recurring themes and knowledge gaps, and make recommendations for future research.

Methods: For this scoping review, PubMed, Scopus, Web of Science, and EBSCO were searched for relevant studies published between 2011 and 2023. Gray literature was searched for on ProQuest and Google Scholar. The results were exported from the database into CADIMA for screening and data analysis; 1608 references were screened. Twelve primary studies (n = 12) were included in the final review.

Results: The evidence map found that a link has been established between food and non-alcoholic beverage marketing and enhanced interest in these products from adolescents, although traditional forms of advertising have become less relevant and new forms have emerged. The evidence indicated that food and non-alcoholic beverage marketing is prevalent in schools and influences the food preferences and consumption of school-going children. Additional contributing factors identified were the availability, affordability and accessibility of these products and peer influence.

Conclusion: Policymakers and other relevant stakeholders should focus on the school food environment as a setting and opportunity to positively influence children and adolescents' food choices and consumption habits. More research needs to be conducted in this field, primarily focusing on the internal school food environment. Future research may be broadened to assess the long-term impact of food and non-alcoholic beverage marketing targeted at children and adolescents.

II-P-G.09

The Importance of BMI Categories for Motor Competence in Rural Spanish Adolescents: Insights Beyond Gender Differences

M. Llorca Rodríguez¹, M.V. García-Coll¹, A. Jiménez Marín¹, A. Dorado Suárez¹, E. Cabanillas Cruz¹, E. Martín Moraleda¹, C. Romero Blanco², S. Aznar Laín¹

¹University of Castilla-La Mancha, Faculty of Sport Sciences, Toledo, Spain, ²University of Castilla-La Mancha, Faculty of Nursing, Ciudad Real, Spain

Purpose: This study aimed to explore sex-based differences in motor competence and assess how motor competence varies across BMI categories among early adolescents in rural secondary schools of Castilla-La Mancha. By focusing on a typically underrepresented rural population, the research provides insights into how sex and body composition influence motor skill development, informing targeted strategies to promote physical literacy and health during adolescence.

Methods: A cross-sectional design was used with 210 first-year secondary students (108 boys, 12.24±0.68 years; 102 girls, 12.12±0.64 years) from 11 rural schools participating in the "Motor Competence in Castilla-La Mancha" project. Motor competence was measured using the Körperkoordinationstest für Kinder (KTK), comprising side jumps, moving sideways, single-leg jump, and backward balance, summarized as a Motor Quotient (MQ). BMI was calculated from measured height and weight, and participants were classified into four categories: thinness, normal weight, overweight, and obesity. Sex differences were analyzed using independent t-tests or Mann-Whitney U tests. Differences across BMI groups were examined using one-way ANOVA with Bonferroni or Games-Howell post-hoc tests. Chi-square tests assessed sex distribution across BMI categories. Significance was set at p≤0.05, with effect sizes reported.

G. CHILDREN AND FAMILIES

Results: No significant sex differences were found in BMI distribution. Boys scored significantly higher than girls in overall MQ (89.94 ± 20.03 vs. 81.38 ± 18.39 ; $p < 0.001$; $ES = 0.43$) and in all KTK subtests. A significant main effect of BMI was observed ($p < 0.001$; $ES = 0.312$), with overweight and obese adolescents showing lower MQ scores than their normal-weight and thin peers. No significant BMI $\times$ sex interaction was found, although sex differences were only significant in the normal-weight group.

Conclusion: Motor competence was higher in boys than girls, and excess weight was consistently associated with reduced motor proficiency. These findings underscore the importance of considering BMI categories when assessing motor development and designing interventions. Since sex differences were only evident in normal-weight adolescents, BMI appears to be the dominant factor influencing motor competence. Promoting motor competence in adolescents with overweight or obesity may be key to enhancing physical activity engagement and reducing health disparities in rural youth.

II-P-G.10

Researching School Food in Special and Alternative Provision Schools: A Reflection on Suitable Qualitative Methods

S. Clohessy¹, E. Sevel¹, M. Murphy¹, J. Tanner¹, E. Hope², I. Brownlee², G. Defeyter², M. Pallan¹, S. Friedman³

¹University of Birmingham, Department of Applied Health Sciences, Birmingham, United Kingdom, ²Northumbria University, Newcastle upon Tyne, United Kingdom, ³University of Edinburgh, Moray House School of Education and Sport, Edinburgh, United Kingdom

Purpose: In this study, we sought to understand how pupils in special and alternative provision schools in England perceive and experience school food, including factors shaping food choices, facilitators and barrier to healthy eating, and food-related learning. Children attending these schools have varied special educational needs and disabilities, yet their perspectives are often absent from school food research and there is a lack of literature guiding inclusive research practice for engaging this group. In the current analysis, we aimed to reflect on the suitability of the qualitative methods employed and consider learnings for future research with this population group.

Methods: Flexible qualitative research methods were developed with advice from experts and community advisors, and tailored to diverse communication styles and cognitive profiles, including adaptable assent protocols and a multi-modal data collection toolbox. We evaluated our methodological approach using engagement metrics, researcher fieldnotes and reflections, and post-project researcher workshops. Analysis was conducted using Reflexive Thematic Analysis.

Results: Three themes were developed capturing methodological reflections, highlighting challenges and learnings in eliciting pupils' experiences of school food.

Preparation – best intentions and clear communication: the broad project scope, requesting exploration of both special and alternative provision schools, was challenging to suit the highly varied needs of pupils across settings. Time invested establishing familiarity and adapting communication approaches with pupils was essential in supporting pupils to express preferences and experiences of food and eating in school.

During – rigorous but dynamic practice: data collection required balancing responsiveness to pupils' communication styles while ensuring ethical and methodological rigour, particularly when managing the risk of supporting school staff influencing pupils' responses. Ongoing reflexive decision-making and adaptation was essential.

Next time – more time, training, and information: researchers emphasized the need for extended time to understand pupils' communication styles, along with clearer guidance and researcher training to navigate ethical and methodological complexities of engaging pupils with cognitive and learning disabilities whilst capturing their views on school food experiences in a meaningful way.

Conclusion: These methodological reflections will support researchers in engaging pupils with special educational needs and disabilities, and capturing their school food perspectives and experiences, advancing inclusive, rigorous, and context-sensitive behavioural nutrition research.

G. CHILDREN AND FAMILIES

II-P-G.11

Engaging Faith-based Organizations in Obesity Prevention Intervention: Lessons Learned from the LA CASA Trial

E. Feliciano¹, J. Gittelsohn², J. Rodriguez¹, A. Pham¹, M. Rojo¹

¹University of Arkansas for Medical Sciences, College of Nursing, Little Rock, United States, ²Johns Hopkins University, Bloomberg School of Public Health, Baltimore, United States

Purpose: Childhood obesity disproportionately affects Hispanic children in the United States, with over half of Arkansas students classified as overweight or obese. Faith-based organizations (FBOs) are promising but underutilized settings for culturally responsive interventions within Hispanic communities. Despite this potential, few obesity prevention programs have been tailored for this population. This formative work describes the lessons learned from community engagement efforts for the LA CASA trial, a healthy eating intervention designed to address this gap through meaningful partnerships with local churches.

Methods: An exploratory qualitative design was employed, utilizing detailed field notes to document the recruitment and engagement process in eight Catholic churches; four in the control group and four in the intervention group, throughout the state of Arkansas. A total of 39 field notes were documented promptly following site visits and analyzed using rapid analysis and iterative techniques to identify recurring challenges, facilitators, and contextual insights related to community engagement.

Results: Initial engagement work in 2023 identified potential churches through site visits, participation in church events, and establishing contact with key personnel, which laid the foundation for recruitment. The subsequent formal recruitment phase yielded essential themes for successful collaboration. *The Necessity of Presence was shown through* consistent physical attendance at church activities such as masses, bible studies, and food festivals to build trust. *Engagement of Gatekeepers* required 1-2 initial visits with FBOs, followed by additional 2-3 visits to secure formal permission from church leadership. However, *Permission is Necessary but Insufficient*, as official leadership approval did not guarantee community buy-in. The *Critical Role of Champions* proved that collaboration with internal, devoted congregants and influential lay leaders was crucial for engagement. Finally, *Sustainability Through Responsiveness* was fostered through ongoing active participation and health teachings based on congregant's expressed needs and interests.

Conclusion: Successful FBO engagement requires deep community integration founded on trusted relationships, consistent presence, and cultural humility. The identified themes provide a strategic framework for developing sustainable health promotion interventions and improving engagement and recruitment within Hispanic communities.

II-P-G.12

Feasibility and Preliminary Efficacy of DC-SIPS for Reducing Sugary Drink Consumption among Black Youth in Washington D.C

M.F. Grilo¹, N.I. Boldrick^{2,3}, N.J. Vallone¹, J. Sacheck⁴, W.D. Evans¹, A.C. Sylvetsky¹

¹The George Washington University, Department of Exercise and Nutrition Sciences, Washington, United States,

²Children's National Hospital, Washington, United States, ³The George Washington University, School of Medicine and Health Sciences, Washington, United States, ⁴Brown University School of Public Health, Department of Behavioral & Social Sciences, Providence, United States

Purpose: To assess the feasibility and preliminary efficacy of DC-SIPS (Decreasing Children's Sugar Intake through Pediatricians and Social Marketing), a six-week intervention to reduce sugary drink intake and promote water consumption among Black youth in Washington, DC.

Methods: Children aged 11–17 years (n = 14) and their parents were recruited from multiple clinical and community locations in the Washington, D.C. area. Eligibility criteria included the child self-identifying as African American/Black, consuming ≥5 servings of sugary drinks per week (e.g., soda, fruit juice, fruit drinks, sports drinks, or sweet tea), and reporting that they and their parent used Instagram daily. During a virtual enrollment visit, children completed a beverage intake questionnaire and participated in a motivational interviewing session with a trained research assistant. Over six weeks, participants received daily DC-SIPS content via Instagram, including goal prompts, nutrition education, and healthy-drink challenges. Feasibility was evaluated through recruitment, retention, and weekly questionnaire completion rates. Preliminary efficacy was examined by comparing weekly self-reported beverage

G. CHILDREN AND FAMILIES

intake (oz/day) at baseline and throughout the six-week intervention. Data were analyzed using mixed-effects linear regression models.

Results: The study completion rate was 79% (11 of 14 children), and children's total sugary drink consumption decreased from 67.5 ± 19.8 oz/day at baseline to 52.6 ± 21.4 oz/day at week six. Compared to the baseline, mean intake was significantly lower at week 2 (-51.4 oz, $p = 0.004$), week 4 (-49.0 oz, $p = 0.035$), and week 6 (-50.3 oz, $p = 0.023$). Fruit drink intake showed a significant linear decline over time ($\beta = -1.9$ oz/week, $p = 0.029$) and was consistently lower from weeks two-seven (all $p < 0.05$). Water consumption remained stable over the seven weeks (38.3 ± 5.9 oz/day at baseline and 35.5 ± 7.6 oz/day at week six).

Conclusion: DC-SIPS demonstrated good feasibility among Black children in Washington, D.C., and led to reductions in children's sugary drink consumption without reducing water intake. These results support the preliminary efficacy and scalability of a pediatric- and social media-based intervention and justify further evaluation in a larger randomized controlled trial.

II-P-G.13

Co-design of a Digital Support Tool for Promoting Healthy Lifestyle Behaviors during Infancy (Health4Life): A Formative Study with Child Healthcare Nurses and Parents in Sweden

C. Alexandrou Hultman¹, M. Golsäter², A. Strid¹, M. Löf^{1,3}, K. Hesketh³, C. Delisle Nyström^{1,3}

¹Karolinska Institutet, Department of Medicine, Huddinge, Stockholm, Sweden, ²School of Health and Welfare, Jönköping University, Department of Nursing, Jönköping, Sweden, ³Deakin University, Institute for Physical Activity and Nutrition (IPAN), Geelong, Australia

Purpose: In Sweden, child health services play a key role in supporting parents to establish healthy lifestyle behaviors in their children from birth through the first five years of life. Yet, support between routine visits remains limited, pointing to a gap in accessible evidence-based guidance for parents. Digital tools offer promising opportunities to address this gap. This study aimed to co-design the Health4Life app in collaboration with child healthcare professionals and parents of young children.

Methods: A co-design approach guided the development of Health4Life's content and layout. Initial semi-structured interviews with parents ($n = 5$; with a child aged 0-2 years) and a focus group with child healthcare professionals (nurses, $n = 4$ and a pediatric dietitian) identified key needs and informed a first version. Two additional focus groups with the same group of professionals provided formative feedback on content and features in the app. A prototype was then tested for two weeks by the same professionals and parents, followed by a focus group and interviews to refine tone, wording, layout, and functionality. Data was analyzed using inductive latent thematic analysis.

Results: The initial interviews with parents and professionals revealed key support areas during the child's first year and information gaps (e.g., food introduction, feeding challenges, sleep strategies). Both informant groups emphasized the value of a digital tool offering clear, concise guidance from a trusted source, i.e., child health services. Commercial apps were described by both parents and professionals as containing a mix of reliable and questionable information. Professionals also discussed how commercial apps often promoted excessive tracking of babies' feeding and sleep patterns and highlighted the importance of flexible, non-rigid content that encouraged reflection, which could empower parents to trust their instincts and normalize differences in child development. Both informant groups stressed the need for a supportive, reassuring tone and features such as simple, visual content, multilingual options, easy navigation, and optional interactive features like milestone tracking and recipe/play ideas.

Conclusion: There is a strong need for a trustworthy, evidence-based, and user-friendly app that promotes healthy lifestyle behaviors in infancy and early childhood while fostering reflection and empowering parents.

Improvements in Food Literacy among Children Participating in School-based Experiential Food Education

C. St. Pierre¹, C. LeBlanc¹, R.M van Dam¹, J.M Sacheck²

¹The George Washington University Milken Institute School of Public Health, Exercise and Nutrition Sciences, Washington, DC, United States, ²Brown University School of Public Health, Behavioral and Social Sciences, Providence, United States

G. CHILDREN AND FAMILIES

Purpose: Children engaged in experiential food education demonstrate greater willingness to try new foods. School-based programs offer a key opportunity to consistently reach children at risk for low-quality diets; however, little is understood about the influence of these programs on the factors that shape dietary patterns as children mature. This study examined changes in food literacy among children participating in a school-based experiential food education program and explored differences according to prior program exposure.

Methods: In the 2024-25 school year, 4th and 5th grade students at 6 elementary schools with at least 3 prior years of continuous program participation and 2 schools implementing the program for the first time were recruited to participate. The Food Literacy BITE survey, a novel food literacy assessment tool developed from four child-centered food literacy dimensions, was administered in October 2024 and again in May/June 2025. Analyses were conducted at the group level, and pre/post mean scores for overall food literacy and each dimension were compared using *t* tests ($p \leq 0.05$). We also carried out stratified analyses to explore differences between the established and new program schools.

Results: A total of 545 students completed the pre-survey (48% 4th grade, self-report ~44% female, ~42% male), and 556 students completed the post-survey (52% 4th grade, ~46% female, ~43% male). There was a significant increase in total food literacy ($p = 0.046$) and in the dimensions of food systems and nutrition knowledge ($p = 0.01$) and confidence in everyday food skills ($p < 0.001$) from the start to the end of the school year. In the stratified analyses, both the established ($p < 0.001$) and new ($p = 0.03$) schools had increases in confidence in food skills, but only the established schools had increases in knowledge ($p = 0.01$) and total food literacy ($p = 0.03$).

Conclusion: Food literacy increased over the school year among 4th and 5th grade students participating in an experiential food education program, specifically in the areas of knowledge and confidence in their food skills. Further research is needed to understand the dose-response relationship over multiple years of program participation.

II-P-G.16

What Do Swiss Children and Adolescents Eat? Results from menuCH-Kids, the First Swiss National Nutrition Survey

J. Vincentini¹, E. Hillesheim², E. Mehner³, T. Nemecek³, A. Chatelan², M. Bochud¹

¹Unisanté, University Center for Primary Care and Public Health, Department of Epidemiology and Health Systems, Lausanne, Switzerland, ²HES-SO University of Applied Sciences and Arts Western Switzerland, Geneva School of Health Sciences, Department of Nutrition and Dietetics, Geneva, Switzerland, ³Agroscope, Life Cycle Assessment Research Group, Zurich, Switzerland

Purpose: The menuCH-Kids survey provides the first nationally representative data on diet and diet-related health of Swiss children and adolescents (CA). This work compares CA's diets to nutritional recommendations and identifies dietary patterns. By linking these patterns to sociodemographic characteristics, and subsequently to health indicators and environmental impacts of foods, we aim to identify subgroups among Swiss CA who would benefit most from targeted strategies promoting healthier and more sustainable diets.

Methods: menuCH-Kids is a cross-sectional, population-based survey conducted in 2023–2024 in six Swiss centres among 1,852 CA aged 6–17 years. Data collection included two non-consecutive 24-hour dietary recalls (24HDRs) and a food propensity questionnaire (FPQ), complemented by lifestyle, health, and sociodemographic information, anthropometric measurements, and blood and urine samples. Usual intakes of food groups will be derived from 24HDRs and FPQ using SPADE and compared to European recommendations. We will use the partitioning around medoids method to explore dietary patterns, and characterize the distribution of socio-demographic variables (e.g. sex, age, linguistic region, socioeconomic status) across patterns. The distribution of some health variables, like BMI, blood pressure and blood parameters, will also be compared across patterns. Based on the environmental impact of foods, calculated using the SALCA v2.01 method, we will estimate the impact of each food group and each eating habit.

Results: Initial findings indicate suboptimal dietary intakes among Swiss youth, characterized by high consumption of meat, snacks, and sugary drinks, alongside insufficient intake of fruits, vegetables, and plant-based protein sources. We will present detailed quantification of these gaps relative to recommendations. We will also show the analysis of distinct dietary patterns, their sociodemographic distribution and their relation to health variables. Preliminary data relative to environmental impact will be presented.

Conclusion: First menuCH-Kids results highlight the need for dietary improvements among CA in Switzerland. The upcoming analysis of dietary patterns, and their associations with the sociodemographic and health characteristics of CA and the environmental impact of food will provide crucial insights for identifying population groups that could benefit from targeted interventions promoting healthier and more environmentally sustainable eating behaviours in CA.

II-P-G.17

Promoting Healthy Eating Behaviors among Mother-daughter Dyads in Group-based Interventions: Design of an Attention Control Condition

G.X. Ayala¹, E. Gomez², T. Baranowski³, N. Ayala⁴, O. Lafuente⁴, D. Chagolla⁴, K. Butte⁵, L. Brookman-Frazee⁶, M. Flores⁴, J. Schneider⁴, S. Roesch⁷, E. Arredondo⁷

¹San Diego State University, School of Public Health, San Diego, United States, ²SDSU-UCSD Joint Doctoral Program in Public Health, Health Promotion, San Diego, United States, ³Baylor College of Medicine, Pediatrics-Nutrition, Houston, United States, ⁴Institute for Behavioral and Community Health, SDSU Research Foundation, San Diego, United States, ⁵Seattle Pacific University, Department of Health and Human Performance, Seattle, United States, ⁶UCSD School of Health Sciences, Department of Psychiatry, La Jolla, United States, ⁷San Diego State University, Department of Psychology, San Diego, United States

Purpose: The US population is not meeting dietary guidelines. This study extends evidenced-based family intervention strategies by adapting and testing a mother-daughter intervention to promote healthy eating. The purpose of this presentation is to share the intervention adaptation process and the resulting Conmigo Healthy Eating intervention.

Methods: Intervention adaptations were informed by several considerations, including:

- (1) the context of intervention implementation-elementary schools, attention control condition, US-Mexico border region;
- 2) the focus on mother-daughter dyads versus individual family members or the whole family as in previous studies; and
- (3) relevant evidence-based processes of change (e.g., parenting, dietary behavioral strategies).

Results: Findings from considering each informed the development of a 10-session intervention to promote the consumption of fruits, vegetables, and fiber. For example, consistent with consideration (1), we reduced the length of the intervention to align with the elementary school academic calendar. In addition, the overall study design is a clustered randomized controlled trial in which schools are randomized to deliver a physical activity intervention or an attention control condition – this healthy eating intervention. Designing an effective attention control condition that involved a second health behavior related to common health conditions in the communities of interest (e.g., obesity, diabetes) required us to:

- (a) design a structurally equivalent program (e.g., time, attention, setting);
- (b) maximize equivalent participant engagement (e.g., with delivery and contents);
- (c) monitor and reinforce standardization in delivery to minimize confounders; and
- (d) strive for equivalent evaluations of potential program benefits).

Consistent with consideration (2), we modified the focus of goal setting and home practice to the mother/daughter dyad (vs. individual or family as in previous studies). Consideration (3) ensured that we maintained a focus on strengthening mothers' parenting strategies (e.g., monitoring, limit setting) that have mediated improvements in children's eating habits in previous studies.

Conclusion: This presentation shares important findings on considerations in the design of dyadic-based interventions for the promotion of an important healthy lifestyle. Designing contextually and culturally relevant interventions necessitates an understanding of the systems and people involved in implementation, as well as those the interventions seeks to reach.

II-P-G.18

Broadening Movement Possibilities: Understanding the Impact of After-school Outdoor Loose Parts Play on Children's Physical Activity and Physical Literacy

M. Stone¹, J. Campbell¹, M. Locke¹, N. Joshi¹, B. Feicht¹

¹Dalhousie University, Department of Health and Human Performance, Faculty of Health, Halifax, Canada

Purpose: Outdoor loose parts play (OLPP) increases play possibilities by giving children the opportunity to combine open-ended materials and create their own play experiences. Research has linked OLPP to physical activity (PA) and physical literacy (PL) in early childhood, but more is needed in school-age children, particularly mixed-methods and participatory approaches, and including not only adults' perspectives but also children's. Purpose: To explore staff and child perspectives of an after-school OLPP intervention in supporting children's PA and PL.

G. CHILDREN AND FAMILIES

Methods: This analysis is based on data from the Physical Literacy in the Early Years (PLEY) School project, a six-week OLPP intervention in three after-school programs in Nova Scotia, Canada. Each received the same loose parts (LP) kit (tree cookies, pool noodles, tarps, logs, balls, pipes, tubes, wooden planks, spools, rope, buckets, hula hoops, tires). Qualitative data from focus groups (15 staff) and photo-documentation (n=50) and go-along interviews and photo-elicitation with children (n=11, 16), were explored using reflexive thematic analysis.

Results: Four themes describe OLPP's contribution to children's PA and PL. "Energizing Exploration: The Spirit of Play with Loose Parts" relates to PL's affective and behavioural components, with LP providing a fun, engaging experience that gave children confidence and motivation to be active. "Adaptable Adventures: Dynamic Play in Loose Parts Landscapes" describes how LP's flexibility supported physical engagement and imaginative, collaborative, inclusive play, and deeper interactions with outdoor environments. "Motion Medley: Diverse Movement with Loose Parts" highlights how LP encouraged diverse and sometimes risky movements, often in combination, supporting movement competence and confidence and motivating disengagement from sedentary activities. "Brainy Building: Nurturing Mindful Movement through OLPP" demonstrates how OLPP encouraged movement experimentation, cognitive engagement, communication, and teamwork, heightening body awareness and increasing confidence and motivation to engage in active play.

Conclusion: OLPP is perceived by adults and school-age children to offer children opportunities to move in diverse and sometimes risky ways and develop key movement skills that support confidence and motivation to move, and understanding of the value of moving, including with others. Our findings provide further evidence, including children's perspectives, of OLPP for supporting PL and lifelong PA.

II-P-G.19

Does Walking to School Influence Brain Health Outcomes? Evidence from the ActiveBrains Study

D. Rodriguez-Sanchez¹, M. Herrada-Robles¹, M. Atencia Rodriguez¹, F.J. Huertas-Delgado², P. Chillón¹, F.B. Ortega^{1,3}, C. Cadenas-Sanchez^{1,4}

¹University of Granada, Faculty of Sport Sciences, Department of Physical Education and Sports, Granada, Spain, ²La Inmaculada Teacher Training Centre, University of Granada, Department of Visual, Music and Corporal Expression, Granada, Spain, ³University of Jyväskylä, University of Jyväskylä, Jyväskylä, Finland, ⁴Instituto de Salud Carlos III, CIBER de Fisiopatología de la Obesidad y Nutrición (CIBEROBN), Madrid, Spain

Purpose: To examine differences between walking and passive commuting to school in psychological, cognitive, intelligence, academic, and brain magnetic resonance imaging (MRI) outcomes, and to further analyze the associations between estimated step count and brain health outcomes in children with overweight or obesity.

Methods: A total of 107 Spanish children (40.2% girls; 10.0 ± 1.1 years) from the ActiveBrains project participated. The usual mode of commuting to and from school was self-reported and categorized as walking vs passive. Psychological well-being, cognitive performance, intelligence, and academic achievement were evaluated using standardized questionnaires and neuropsychological tests. Brain MRI outcomes were derived from 3T structural scans. Estimated steps were computed from the reported home-school distance and measured height (steps = distance ÷ 0.42 × height). Analyses were performed in walkers only, adjusted for sex, peak height velocity, parental education, body mass index, and moderate-to-vigorous physical activity; total brain volume was additionally included for MRI outcomes. Linear regression models were fitted to analyze the associations between estimated step count and brain health outcomes.

Results: Children who walked from home to school reported higher happiness (p = 0.049) and better math performance (p = 0.037) than passive commuters. Those who walked to school showed greater pallidum volume (p = 0.039) and tended to present larger accumbens volume (p = 0.066). No significant associations were observed for the remaining psychological, cognitive, intelligence, or structural measures. Estimated steps to and from school were not significantly related to any brain outcomes.

Conclusion: Walking to school was not associated with most brain outcomes. Nonetheless, small and suggestive advantages in happiness, academic performance, and subcortical brain volumes were observed. Future research should examine the dose-response relationship of walking to school to further explore its potential links with brain health.

II-P-G.20

Preliminary Efficacy Outcomes of Two High School MyPlate Ambassador Curricula in the United States

J. Szeszulski¹, M. Putnam², K. Marstall¹, A. MacMillan Uribe¹, C. Rethorst¹, J. Gardner³

¹Texas A&M AgriLife Research, Dallas, United States, ²Tulane University, Department of Epidemiology, New Orleans, United States, ³Texas A&M AgriLife Extension, College Station, United States

Purpose: There are many benefits for youth engaging in healthy eating habits that follow the 2020-2025 Dietary Guidelines for Americans (e.g., reduced chronic disease risk). However, nutritional education programs across the U.S. can vary markedly, with two innovative approaches focusing on providing peer-to-peer education, and creating policy systems, and/or environmental change. This study evaluated and compared two new MyPlate ambassador curricula that used these approaches for improving nutritional outcomes among high school students.

Methods: In curriculum one, MyPlate Influencers execute a nutrition-focused environmental change project in their schools (e.g., taste testing recipes, enhancing local wellness policies, hosting agriculture events). In curriculum two, MyPlate Educators provide peer-to-peer education to younger students. A non-randomized, two-arm study design, paired sample t-tests, and linear regression models were used to evaluate (single arm pre-test to post-test changes) and make comparisons between the two curricula. We evaluated Healthy Eating Index (HEI), theory of planned behavior constructs around healthy eating, and household nutrition security outcomes and subconstructs.

Results: Ambassadors (n=50; 74.0% female; 15.8±1.1 years old) self-selected into Educator (n=30; 73.3% female; 15.9±1.2 years old) and Influencer groups (n=20; 75.0% female; 15.6±1.0 years old). Across both groups, we saw a statistically significant increase in the household healthfulness subconstruct within the food and nutrition security questionnaire (MD=0.59±1.65; p=.046; d=1.65), which was slightly larger for Educators (MD=.70±1.74; d=.40) than it was for Influencers (MD=.36±1.50; d=.24). Conversely, Influencers increased their HEI scores (MD=2.38±7.89; p=.297; d=.30), whereas Educators decreased their HEI scores (MD=-2.00±5.70; p=.107; d=-.35), but the between group difference was not statistically significant (b=2.74; 95%CI=-1.36-6.83; p=.184). Finally, Influencers also saw marginal increases in their subjective norms (MD=0.55±0.93; p=.082; d=.58) and perceived behavioral control (MD=0.36±0.50; p=.038; d=.72) around healthy eating, but changes were not statistically significant compared to Educators.

Conclusion: Preliminary data show that the Influencers may be improving individual level outcomes – subjective norms, perceived behavioral control, and diet quality – whereas Educators may be influencing their home environments. Given the small sample size, more research is needed to confirm (i.e., larger sample) and better understand (i.e., qualitative interviews) the reasons for these findings.

II-P-G.21

Bridging School and Home: Engaging Parents in Nutrition Education Interventions at Primary School

G. Zeinstra¹, H. Snoek¹, L. Van Bussel²

¹Wageningen University & Research, Wageningen Social & Economic Research, Wageningen, Netherlands, ²Wageningen University & Research, Wageningen Food & Biobased Research, Wageningen, Netherlands

Purpose: Schools form an ideal setting to reach children from diverse backgrounds with nutrition education programs. Research suggests that involving parents can enhance the effectiveness of such programs, yet it remains unclear which forms of parental involvement work best and how these are perceived in practice. This project investigated which types of parental involvement are used in primary school nutrition interventions, and assessed their perceived acceptability, feasibility and effectiveness.

Methods: Expert interviews (N=6) and a literature scan (N=34) were executed to identify existing forms and success factors of parental involvement. Subsequently, nine focus groups were held with teachers (N=8), parents (N=9), and youth health professionals (N=10) to investigate their perceptions about various forms of parental involvement. Thirdly, a survey was conducted among 1,000 parents (54% female; average age 39 ± 6 years). Finally, an online stakeholder session was held to reflect on the project's findings.

Results: School-based nutrition education interventions used various forms of parental involvement. The 19 identified forms were categorized according to two dimensions: location (school versus home) and role of parents (active contributor versus recipient). Each form had advantages and disadvantages. The aspects acceptance, feasibility, and reach were not always aligning. For instance, parents rated parent-child activities at school (mean M=5.1 out

G. CHILDREN AND FAMILIES

of 7) and practical assistance by parents (M=5.3) highest in terms of acceptance, but lowest in feasibility (M≤4.6). In contrast, school food policies scored highest on feasibility (M=5.3), reach (M=5.3), and expected effectiveness (M=4.8), but lowest on acceptance (M=5.0).

Key facilitators of acceptability were: interactive, child-centred, matching parents' interest, informal, acknowledging social norms and the sensitivity of topics. To support feasibility, parental involvement should be well-timed, convenient in terms of effort, costs, materials, and time-effective for both schools and parents. For reaching a large and diverse number of parents, culture, language and direct contact were important themes.

Conclusion: There is no silver bullet of parental involvement. Each form has its own advantages and disadvantages, with acceptance, feasibility, and reach not always aligning. It is recommended to use a variety of approaches over time tailored to the specific school context.

II-P-G.22

Integrating Promotion of Safe Psychosocial Family Environment in Early Obesity Prevention – An Innovative Approach Adapted by the Danish Bloom Study

M. Rasmussen¹, R. Rothkegel Carlsson¹, M. Pil Jensen¹, L. Kierkegaard¹, T. Risager Ubbesen¹, K. Rick Madsen¹, T. Pagh Pedersen¹, C. Thørring Bonnesen¹

¹University of Southern Denmark, National Institute of Public Health, Copenhagen, Denmark

Purpose: To date the effectiveness of obesity preventive interventions is limited and observed effects tend to be modest and not sustained over time. This reflects the complex etiology and difficulties in translating evidence into effective intervention designs.

A growing area within empirical and theoretical research on the causes of childhood obesity relates to psychosocial strain during the early years of life. Growing empirical evidence documents an independent effect of family-related psychosocial strain, while experimental evidence is still limited.

The purpose of this study is to present the components promoting safe psychosocial family environment integrated into the Danish Bloom Study aiming at promoting healthy weight development in infancy. The study presents implementation strategies and intervention components applied to promote safe psychosocial family environment.

Methods: The Bloom Study is a randomized intervention study integrated in the universal Danish system of community health nurses (CHN) to promote healthy weight development among infants. The Danish standard CHN service is offered to all families with newborns and provides guidance and support tailored to each family's circumstances and needs. The Bloom Study explores the potential of the CHN service for promoting healthy weight development by strengthening a number of priority areas, including an innovative focus on supporting a safe psychosocial family environment. Specifically, the Bloom Study aims at increasing parental self-efficacy, decreasing parental stress and supporting parents in developing realistic expectations about parenting.

Results: The applied implementation strategies supporting safe psychosocial family environment includes CHN competence building on supporting parents in meeting their child's socioemotional needs and on health communication across social diversities. Intervention components include application of a dialogue tool to increase CHNs' insights into the needs of the family, early detection of perinatal depression among both parents, and social support for both parents through membership of parent-groups. Generally, the Bloom intervention involves prolonged and continuous guidance and support to the family.

Conclusion: The Bloom Study is one of the first experimental studies on obesity prevention examining the effect of supporting safe psychosocial family environment. The results will increase the causal understanding of childhood obesity and generate important experiences relevant for both practice and future experimental designs.

II-P-G.23

Exploring Gender Roles in Family Eating Practices as Experienced by Mothers with a History of Gestational Diabetes Mellitus

L. Laberee^{1,2}, J. Robitaille^{1,2}, I. Auclair Mangliar³, A.-S. Morisset^{2,3,1}, C. Simoneau², É. Carbonneau^{1,2}, S. Desroches^{1,2}, M. Turcotte², V. Provencher^{1,2}

¹École de Nutrition, Faculté des Sciences de l'Agriculture et de l'Alimentation (FSAA), Université Laval, Québec, Canada,

G. CHILDREN AND FAMILIES

²Centre Nutrition, Santé et Société (NUTRISS), Institut sur la Nutrition et les Aliments Fonctionnels (INAF), Université Laval, Québec, Canada, ³Centre de Recherche du CHU de Québec-Université Laval, Université Laval, Québec, Canada

Purpose: Despite fathers' increasing involvement in domestic life, mothers are still primarily involved in food-related tasks such as meal planning, grocery shopping and cooking. This gendered division of domestic labor reinforces gender inequities and may have consequences on mothers' health. Moreover, for mothers who experience gestational diabetes mellitus (GDM), the burden of food-related responsibilities may be further intensified, as diet is central to GDM treatment. This study aims to explore how parental roles are experienced regarding the division of food-related tasks and responsibilities, among mothers with a history of GDM, in Quebec City (Canada).

Methods: This exploratory study, based on a qualitative approach, is part of a larger project (SANTE-DG) launched in April 2025, which aims to recruit a total of 500 mothers and develop postnatal nutrition services for mothers with a history of GDM. During November 2025, this qualitative study is intended to recruit between 10 and 15 mothers from SANTE-DG's cohort, who gave birth between January 2025 and June 2026 and were diagnosed with GDM. From December 2025 to February 2026, individual interviews (n=10 or until data saturation) will be conducted online using a semi-structured guide. Interviews will explore participants' perceptions, attitudes, behaviours and level of satisfaction regarding the division of food-related household tasks. Barriers and facilitators for achieving a more equitable distribution of parental roles in food-related tasks and responsibilities will also be documented. Interviews will be recorded and transcribed with PREDIS software. Through an inductive approach, a thematic content analysis of transcribed verbatims will be performed using NVivo, from January to April 2026. Two meetings with the research team will take place midway through coding to enhance credibility of findings.

Results: Results are not ready by the submission date.

Conclusion: This innovative study addresses a topic that has yet to be thoroughly explored in the literature. By analysing participants' discourse, it will contribute to a deeper understanding of the challenges and realities faced by mothers with a history of GDM in relation to gender roles and social expectations surrounding food practices. This will support the development of appropriate strategies for those mothers to help them adopt healthy eating habits.

II-P-G.24

Youth Sports as a Setting from Promoting Physical Activity among High-risk Mothers: A Pilot Study

T. von Ash¹, B. O'Hagan¹, S. Dunsiger¹, B. Marcus¹

¹Brown University, Behavioral and Social Science, Providence, United States

Purpose: Youth sports are an obvious setting for physical activity (PA) promotion among children, but have yet to be utilized to promote PA among mothers. Interventions delivered to parents through youth sports circumvent physical activity barriers commonly cited by high-risk mothers including racial and ethnic minorities and those with low socioeconomic status (e.g., lack of time and childcare). We partnered with a youth football organization in Providence, RI, USA that predominantly serves low-income Black and Hispanic families to deliver a PA program to mothers, and examined feasibility, acceptability, and preliminary efficacy.

Methods: We conducted a 6-week single-arm open pilot trial of an intervention consisting of group PA sessions facilitated by a certified fitness instructor during practice. Sessions, which included 50 minutes of aerobic activities that encouraged moderate to vigorous physical activity (MVPA), were scheduled 3 times/week. Participants were mothers from the partner organization. Feasibility was determined based on whether enrollment and retention targets were met. Acceptability was determined based on participant engagement and satisfaction. For preliminary efficacy, We ran a series of unadjusted paired T-tests to compare baseline MVPA and PA self-efficacy to MVPA and PA self-efficacy at 3- and 6-weeks. We also conducted a stratified analysis to examine the same changes separately for participants who were already meeting PA guidelines at baseline (i.e., ≥ 150 minutes/week of MVPA) and those who were not meeting guidelines.

Results: We recruited 26 participants in 3 weeks with an 85% retention rate. Only 12 out of 18 scheduled sessions were offered due to practice cancellations; participant attendance ranged from 0 to 12 sessions (mean: 3.5 sessions). Participant satisfaction was extremely high, and significant increases in outcomes were observed. Specifically, we observed significant improvements in self-reported minutes/week of MVPA at 3-weeks, both among the full sample and those who were not meeting guidelines at baseline. We also observed significant improvements in self-efficacy among the full sample at 3- and 6-weeks.

Conclusion: Findings from this pilot trial suggest that youth sports practices may provide a promising opportunity to deliver PA interventions to high-risk mothers, but more studies are needed.

G. CHILDREN AND FAMILIES

II-P-G.25

Triple Feeding Online: An Exploration of Triple Feeding Messaging on Instagram Using Natural Language Processing

L. Camp¹, E. Prud'hommeaux², E. Moreno¹, T. Chernauskas¹, J. Doyle¹, Z. Aghdasi¹, S. St. Pierre¹, H. Wasser³

¹Boston College, William F. Connell School of Nursing, Chestnut Hill, United States, ²Boston College, Department of Computer Science, Chestnut Hill, United States, ³University of North Carolina at Chapel Hill, Nutrition, Chapel Hill, United States

Purpose: While significant strides have been made globally in breastfeeding initiation and continuation rates, rates of sustained breastfeeding at 6 and 12 months continue to fall short of national goals in the United States. Common reasons for early cessation of breastfeeding include low infant weight gain and perceived low milk supply. “Triple feeding” is a trending intervention to address these issues and involves 1) feeding the infant at the breast, 2) hand expressing or pumping any milk remaining in the breast once the infant is done feeding, and 3) feeding the infant expressed milk or formula. Our study team found little scientific evidence regarding the impact and effectiveness of triple feeding, yet there is mounting evidence in grey literature suggesting this intervention places high demands on maternal physical and mental health. Given the interconnection between maternal well-being and breastfeeding duration, additional evidence is needed to explore mothers’ lived experiences and informational influences while triple feeding. Thus, the purpose of this study is to utilize social media data to better understand the messaging mothers receive and share about triple feeding online.

Methods: Data for this project was collected using the Apify API for Instagram. A dataset of 650 Instagram posts containing the hashtag #triplefeeding and 1700 replies to those posts was created. The project team is currently manually tagging all posts and a subset of 500 comments for ternary sentiment (positive/neutral/negative). Using this labeled data, we will train two sentiment analysis methods: (1) fine-tuning a BERT model pre-trained on social media data and (2) few shot learning with Llama 3.1-8B.

Results: The results of the predictive models built in this project will provide a high-level understanding of the triple feeding information delivered through Instagram. Results will also identify triple feeding perceptions and opinions among Instagram users.

Conclusion: Understanding the triple feeding messaging shared on social media will provide a better understanding of 1) information and misinformation available online that could be informing triple feeding practices and 2) mothers’ lived experiences while triple feeding. This information will be useful to clinicians striving to address potential myths and provide better supports to mothers implementing this feeding approach.

II-P-G.27

ReDiKid: Integrating Movement Behaviour and Digital Contexts in the Study of Child Resilience

J. Pelclová¹, J. Suchá^{2,2}, A. Gába¹, T. Větrovský³, ReDiKid Study Group

¹University Palackého Olomouc, Faculty of Physical Culture, Olomouc, Czech Republic, ²University Palackého Olomouc, Faculty of Arts, Olomouc, Czech Republic, ³University of Hradec Králové, Faculty of Science, Hradec Králové, Czech Republic

Purpose: The ReDiKid (Resilient Kid in the Digital World) project introduces a transdisciplinary framework for examining how movement behaviour and digital technologies relate to children’s resilience—their capacity to cope with psychological, physical, and social challenges. It focuses on children aged 9–11 years, a key developmental stage when digital habits, self-regulation, and social skills begin to form, and their families. The project aims to clarify how digital exposure interacts with biological, behavioural, and contextual determinants of resilience and to inform strategies for supporting adaptive digital engagement.

Methods: ReDiKid comprises three research aims:

A) Theoretical Grounding: Establishes a clear definition of children’s digital resilience and identifies key protective and risk factors. Analyses of national and international datasets ensure comparability and a strong conceptual base. B) Empirical Research: Examines how resilience manifests in everyday life among children and parents. It combines longitudinal and cross-sectional designs with both subjective and objective methods. Surveys and interviews assess perceptions and family processes, while ecological momentary assessment (EMA) and wearable sensors capture real-time data on digital behaviour, physical activity, sleep, and sedentary patterns. Resilience is assessed through

G. CHILDREN AND FAMILIES

validated questionnaires. This approach enables understanding of how family context, movement behaviour, and digital engagement influence well-being.

C) Innovative Methods: Develops and tests new objective tools for assessing resilience in middle childhood. Integrates all collected data using Bayesian modelling and machine learning to identify resilience profiles and predictors of adaptation, setting new methodological standards.

Results: Initial testing shows that the ReDiKid design is feasible and effective for capturing subjective and objective aspects of resilience. The framework functions well across diverse data sources, movement behaviour, and family contexts, and refinement continues as data collection progresses.

Conclusion: ReDiKid offers a new, evidence-based approach to understanding and supporting children's and families' resilience in the digital age. By linking theory, movement behaviour, real-world data, and innovative methods, the project provides guidance for education, prevention, and policy.

Active Travel for Care: A Scoping Review and Participatory Study with Caregivers in Toronto, Canada

L. Smith¹, E. Cervinka¹, I. Tiznado Aitken¹, T. Jayaveer¹

¹University of Toronto, Department of Geography and Planning, Toronto, Canada

Purpose: Caregiving sustains the well-being of individuals, households, and society, and an important component of caregiving is the travel required to fulfil responsibilities. Although the frequency of care trips presents an opportunity to integrate physical activity into daily routines and contribute to public health gains, transport planning has typically prioritised economically productive mobility, such as commuting. This research aims to give visibility to the travel needs and experiences of caregivers and to identify barriers and facilitators for incorporating active modes into caregiving trips.

Methods: A scoping review identified 117 articles examining caregivers' active travel behaviours in the context of unpaid household care. Findings were synthesised using Cresswell's framework of mobility (movement, meaning, and experience) through a transport equity lens. In June 2025, seven focus groups and participatory mapping exercises were conducted with 32 caregivers in Toronto, Canada. Maps were digitized to quantify key care destinations, routes, and travel modes, and focus group transcripts were analysed inductively to connect review findings with participants' experiences.

Results: Most articles employed qualitative methodologies and were based in high-income contexts. Care-related travel was predominantly undertaken by women and characterised by short, chained trips but was rarely captured via travel surveys, highlighting gendered inequities in how mobility needs are measured (movement). While active travel was often framed by assumptions of choice, findings demonstrated that mobilities of care are shaped by structural constraints, including car-dependent environments and, conversely, long walking distances in lower-resource settings (meaning). Focus group participants mapped short, active care trips and in line with the review, valued active travel in relation to physical activity, but also for enabling play, family connection, and engagement with nature. Common barriers included inadequate infrastructure, load and logistical demands, safety concerns, and social norms, with participants explicitly linking factors and chosen travel modes with health, time pressures, and stress (experience).

Conclusion: Mobility of care is a key equity issue within active travel and physical activity research. Participatory methods highlighted caregiver's travel experiences, began to address data gaps through trip measurement, and enabled community partnerships to be developed, providing an important step for informing inclusive and healthy planning.

II-P-G.30

Eating Behaviors and Food Parenting Practices with Siblings: Same or Different?

J. Berge¹, E. Ruzicka², M. Edgerley³

¹University of Colorado, Anschutz Medical Campus, Family Medicine and ACCORDS, Aurora, United States, ²University of Colorado, Anschutz Medical Campus, ACCORDS, Aurora, United States, ³University of Colorado, Anschutz Medical Campus, ACCORDS, Aurora, United States

Purpose: While it is common to have siblings in the household, very little is known about sibling eating behaviors and food parenting practices with siblings. It is also unknown whether parents use similar or different feeding practices with siblings based on individual child characteristics such as gender, weight status, or temperament. This is important to investigate to inform the development of family-based nutrition interventions. The main aim of the current study is to describe the variation in eating behaviors and feeding practices within families with siblings and to determine whether these variations depend on individual sibling gender, weight status, or temperament.

Methods: We analyzed a sibling dyad subsample (n=344 siblings from 158 unique families) from the Family Maters study, a National Institutes of Health (NIH)-funded longitudinal cohort study of families with children in Minnesota from 6 racial/ethnic groups (African American, Native American, Latino/a/e, Somali/Ethiopian, Hmong, and non-Hispanic White). Parents self-reported their feeding practices and child eating behaviors specific to each sibling separately on an online survey at baseline and again 18 months later. Differences across siblings were described, and then estimated using within-family regression models.

Results: Two-thirds of families had siblings with different eating behaviors. Parents engaged in different feeding practices across siblings in more than half of the families. Child eating behaviors differed by sibling gender and weight status, with girl siblings and siblings with overweight/obesity having more unhealthful eating behaviors compared to their counterparts. Food parenting practices differed by sibling gender, with parents engaging in more unstructured food parenting practices with daughters (p<0.01). Food parenting practices also differed by child weight status, with parents engaging in more pressuring-to-eat food with siblings with overweight/obesity (p<0.01). Additionally, food parenting practices differed by temperament, with parents engaging in more food restriction with siblings with difficult temperaments (p<0.05).

Conclusion: Findings showed that sibling eating behaviors and food parenting practices varied depending on sibling sex, weight status, and temperament. Researchers and interventionists working with families with siblings may want to assess for sibling gender, weight status, and temperament when assessing the home food environment or designing family-based interventions within the home environment.

II-P-G.31

Four-month Outcomes of an Efficacy Trial of the Culturally Adapted Healthy Dads Healthy Kids-Hispanic

T. O'Connor¹, A. Jimenez-Garcia¹, A. Alvarez¹, E. Arredondo², A. Beltran¹, S. Musaad¹, A. Sanson¹, M.F. Perea Manzo¹, A. Rayward³, J. Rueda⁴, E. Soltero¹, J. Zachariah⁵, T. Baranowski¹, P. Morgan³

¹Baylor College of Medicine, USDA/ARS Children's Nutrition Research Center, Department of Pediatrics, Houston, United States, ²San Diego State University, Department of Psychology, San Diego, United States, ³University of Newcastle, Global Sport and Movement Collaborative, School of Education, Newcastle, Australia, ⁴Baylor College of Medicine, Division of Internal Medicine, Department of Medicine, Houston, United States, ⁵Baylor College of Medicine, Division of Pediatric Cardiology, Department of Pediatrics, Houston, United States

Purpose: To assess the efficacy of a culturally adapted version of the evidence-based program, Healthy Dads Healthy Kids (HDHK), among Hispanic fathers and children in the Houston community to reduce cardiovascular health disparities faced by both. Hispanic fathers have been largely underrepresented in family-based health promotion research.

Methods: A family randomized controlled group treatment trial was conducted involving Hispanic fathers with BMI>25, but <40 kg/m² and their 5-11-year-old children. The HDHK-Hispanic 10-week program was delivered at YMCA Centers on Sundays. Two primary outcomes were assessed: father's weight (kg) and children's moderate to vigorous physical activity (MVPA) via hip-worn accelerometers for 7 days. Secondary outcomes included dietary intake measured by ASA-24, screen use, BMI (BMIz for children), blood pressure (BP), and heart rate; and for fathers, HgbA1C

G. CHILDREN AND FAMILIES

and non-HDL. In intent-to-treat analysis of 4-month outcomes, generalized linear mixed models assessed outcomes by treatment group, adjusting for waves, children nested within families, and repeated time. The estimate of interest was the parameter estimate for the treatment by time interaction (β).

Results: 187 fathers (mean age 39.9 ± 7.1 years) and 259 children (7.9 ± 1.8 years, 40% girls) were enrolled and randomized to treatment or control groups. Among fathers, 31% had an annual family income $< \$26,000$; 47% had less than high school education; 46% were overweight and 54% obese; 35% had prediabetes; 74% had an elevated non-HDL; and 15% had an elevated BP. Among children, 19% were overweight and 30% obese. Retention at 4 months was 75% of families. Median program attendance was 6 sessions/family for intervention group. There were no significant differences by group for fathers' weight (β 1.0, $p=0.26$) or children's MVPA (β -0.13, $p=0.31$) nor for any of the secondary health or behavior outcomes for fathers or children post-intervention (4-month follow-up).

Conclusion: A community sample at risk for cardiovascular disease was reached, but HDHK-Hispanic did not have an effect on fathers' or children's health or behavioral outcomes at 4-months. The number of sessions attended may be related to the outcomes. Future analyses will include 12-month outcomes and dose response. Additionally, qualitative studies will be done to assess barriers to attendance.

II-P-G.32

Paternal Psychosocial Health at Pregnancy as a Foundation for Caregiving and Feeding Roles

M. Landry¹

¹University of California, Irvine, Population Health and Disease Prevention, Irvine, United States

Purpose: Paternal involvement in infant feeding is increasingly recognized as important for child health outcomes, yet fathers often report lower confidence and engagement in feeding compared to other caregiving tasks. Fathers' psychological well-being, self-esteem, and attachment to their unborn child during pregnancy may establish foundational patterns that influence their later confidence and engagement in feeding and other caregiving behaviors. This analysis characterizes the baseline psychosocial profile of first-time expectant fathers enrolled in the Dad Bod Study, an ongoing longitudinal cohort examining fathers' cardiovascular and psychosocial health across the transition to fatherhood.

Methods: First-time expectant fathers aged 19-39 years were enrolled during their partner's second or third trimester. At baseline, participants completed validated psychosocial assessments including the Bradburn Scale of Psychological Well-Being, Rosenberg Self-Esteem Scale, Antenatal Baby Care Scale, and Paternal Antenatal Attachment Scale.

Results: The sample ($N=118$) has a mean age of 33 years was predominantly White (82.9%), married (93.2%), employed for wages (94.0%), and high-income, with 67.5% reporting annual household income $\geq \$150,000$. Baseline assessments revealed moderate-to-high self-esteem (mean=22.9, $SD=4.7$), with 33.9% scoring in the high range (>25). Psychological well-being scores averaged 1.2 ($SD=1.5$), indicating generally positive affect. Perceived stress levels were low-to-moderate (mean=14.2, $SD=5.8$), with 47.5% reporting low stress, 50.0% moderate stress, and only 2.5% high stress. Social support was robust (mean=4.4, $SD=0.6$). Perceived stress was inversely associated with self-esteem ($r=-0.50$, $p<.001$) and social support ($r=-0.53$, $p<.001$), while self-esteem correlated positively with psychological well-being ($r=0.39$, $p<.001$).

Conclusion: Within this predominantly advantaged sample of first-time expectant fathers demonstrated generally positive psychosocial health entering fatherhood, including moderate-to-high self-esteem, strong social support, and low-to-moderate stress. Fathers with stronger psychosocial resources experienced less stress during the prenatal period. These characteristics provide important context for understanding fathers' subsequent engagement in caregiving activities, including feeding. Longitudinal follow-up will examine how these prenatal factors predict paternal involvement in feeding and other caregiving behaviors.

G. CHILDREN AND FAMILIES

II-P-G.34

The Importance of Authentic Caregiver Involvement in Child Health Research Methods

D. Dutch¹, M. Duffy¹, E. Looney¹, K. Matvienko-Sikar¹

¹University College Cork, School of Public Health, Cork, Ireland

Purpose: Caregivers are central to behavioural child health research, often providing information on themselves and their child(ren). However, little is known about how caregivers interpret and respond to outcome measurement instruments, including surveys and anthropometric tools. This study explored caregivers' experiences with outcome measurement instruments to inform more effective and inclusive measurement practices in child health research.

Methods: Mothers of infants <12 months were recruited via social media to attend online and in-person meetings. Participants could bring their infants to meetings and were compensated for their time. Using a qualitative cognitive interviewing approach, participants completed outcome measurement instruments while verbalising their thought process, facilitated by trained researchers. Participants were prompted to evaluate the outcome measurement instruments through the lens of comprehension, comprehensibility, feasibility, and ease of use. Meetings were audio-recorded, transcribed, and supplemented with field notes. Meeting transcripts were thematically analysed using a combined inductive and deductive approach.

Results: Ten meetings were conducted with eight participants over seven months – six online and four in person at a local community space. Participants reported challenges interpreting outcome measurement instruments, including unclear terminology, and varied preferences for question design, response format, and recall period. Parenting experience influenced how outcome measurement instruments were interpreted and completed, underscoring the need for tools that are adaptable to diverse caregiver contexts. Participants valued the meetings as an opportunity to share their perspectives and reflect on how their lived experiences shaped their engagement with child health research.

Conclusion: Findings highlight the importance of involving caregivers in the development and selection of outcome measurement instruments to enhance data quality and participant engagement. This study offers novel insights into caregiver-centred measurement and emphasises the value of recognising diverse caregiver experiences. Fostering a respectful, flexible, and inclusive research environment is essential to obtaining authentic and meaningful data, but also for improving the design, relevance, and impact of child health research.

II-P-G.35

Mothers' and Fathers' Structure-related Food Parenting Practices and Their Association with Child Food Approach Eating Behaviors during the COVID Pandemic

E. Jansen¹, K. Smith², G. Thapaliya¹, J. Sadler¹, A. Aghababian¹, S. Carnell¹

¹Johns Hopkins University School of Medicine, Department of Psychiatry & Behavioral Sciences, Baltimore, United States,

²Johns Hopkins University School of Medicine, Baltimore, United States

Purpose: During the COVID-19 pandemic, many mothers and fathers spent more time at home with their children, warranting consideration of parenting practices around food during the pandemic as influences on obesogenic eating behaviors among children. Structure-related feeding practices, particularly around snacking, may be particularly challenging yet influential in the pandemic setting. Parent sex and levels of feeding-related co-operation among parents (co-feeding) are understudied potential influences on parent-child feeding relationships.

Methods: We investigated relationships between structure-related parent feeding and child food approach behaviors during the COVID-19 pandemic, while considering potential moderating influences of parent sex and co-feeding levels. An online survey was completed by 318 parents (206 mothers and 112 fathers) of 2-12-year-olds who were living in states with statewide or regional lockdowns in May/June 2020 within the United States. Mothers and fathers were drawn from different families, with each survey corresponding to a unique parent-child dyad. Parental stress/mental health, co-feeding (Feeding Coparenting Scale), structure-related food and snack parenting (Feeding Practices and Structure Questionnaire and Parenting around SNacking Questionnaire), and child eating behaviors (Child Eating Behaviour Questionnaire) were assessed. Relationships of parents' structure-related food and snack parenting practices with their child's emotional overeating and food responsiveness behaviors were examined using structural equation modelling. Further, we investigated whether these relations were moderated by parent sex or

G. CHILDREN AND FAMILIES

level of co-feeding.

Results: Parent sex differences were seen in parental stress, mental health, and co-feeding, but not in structure-related food and snack parenting or child food approach eating behaviors. Structure-related food parenting was negatively associated with emotional overeating. However, structure-related snack parenting was positively associated with emotional overeating and food responsiveness. While regression paths varied between mothers vs. fathers, as well as by co-feeding levels, neither parent sex nor co-feeding levels significantly moderated relationships between parent feeding and child eating variables.

Conclusion: Future studies of food and snack parenting and co-operation in relation to feeding among mothers and fathers within a familial unit may be critical to identify intervention strategies that draw on all family resources to better navigate future disruptive events such as the COVID-19 pandemic.

II-P-G.36

Effectivity and Feasibility of Healthy Lunches at Primary Schools in Rotterdam, the Netherlands

A. Wargers¹, W. Jansen^{1,2}

¹Erasmus Medical Center, Public Health, Rotterdam, Netherlands, ²City of Rotterdam, Social Development, Rotterdam, Netherlands

Purpose: The majority of children show unhealthy eating habits. For children in poverty, this is even a greater public health concern. School meals can contribute to making healthy food accessible for all children. Despite its proven health effects, in the Netherlands it is not common to provide school meals. Instead, children bring their own food from home. It is unclear whether providing healthy school lunches would be feasible and have positive effects in a multicultural city like Rotterdam. Therefore, in this study, we investigate the effectivity and feasibility of providing healthy lunches at primary schools in Rotterdam, the Netherlands.

Methods: Five primary schools in Rotterdam participated in a pilot providing healthy lunches to all children for half an academic year (2023-2024). The lunch concept was co-created by school staff, parents, children and relevant stakeholders in each school. The lunch pilot was evaluated through questionnaires about eating behavior, perceived health, taste preferences, school factors, financial stress of parents and feasibility (children/parents/teachers), observations on the content of food at school (children) and focus groups at the end of the intervention period (parents/teachers). For this study we evaluated pre-post effects of the 18-week school lunch. Quantitative data was analyzed in SPSS, findings will be supported by summarized qualitative data.

Results: Food brought from home is not in line with the guidelines for healthy nutrition. Regarding effectivity, a healthy school lunch significantly increases vegetable consumption and children bring less sweetened drinks from home. Small differences suggest improved taste preferences. However, some negative effects should be further investigated, like an increased consumption of cookies and cake and less breakfast consumption. Regarding feasibility, the satisfaction among children, parents and school staff differed. Many children mentioned they liked their lunch from home more compared to the healthy school lunch. Overall, parents and school staff agree a healthy school lunch is a good initiative, especially for the children who need it.

Conclusion: A healthy school lunch seems necessary and can have positive effects. However, the lunch concept should fit the school to ensure feasible implementation. Those findings can shape policy (both on regional and national level) and optimize practical aspects of implementation.

II-P-G.37

Exposure vs. Experience: A Mixed-methods Study of Objective Food Outlets Measures and Families' Lived Experiences of the Neighbourhood Food Environment

H. Harris¹, V. van Garling², P. Kocken², I. Merkelbach², F. Mölenberg³, W. Jansen³, T. Voortman³, P. Jansen²

¹The University of Sydney, Sydney, Australia, ²Erasmus University Rotterdam, Rotterdam, Netherlands, ³Erasmus MC - University Medical Centre, Rotterdam, Netherlands

Purpose: Neighbourhood food environments are often assumed to directly influence children's diets, yet evidence from quantitative studies is inconsistent. This relationship is likely indirect, operating through parents who interpret,

G. CHILDREN AND FAMILIES

navigate, and act upon the food opportunities around them. This mixed-methods study integrated objective spatial measures of local food outlets with parents' lived experiences to better understand how neighbourhood context shapes family feeding and child diet in Rotterdam, the Netherlands.

Methods: The quantitative phase analysed cross-sectional data from $n=3,739$ children (8y) in the Generation R Study. Geographic Information System measures within 400m of each home captured absolute and relative fast-food outlet exposure, and an overall neighbourhood healthiness score. Diet quality (scored 0-10) was derived from a validated parent-reported food frequency questionnaire. Generalised linear models tested associations between the food environment and child diet, and moderation by maternal education. To further investigate these findings, semi-structured interviews were conducted with $n=15$ parents from socioeconomically diverse neighbourhoods and analysed inductively using a constructivist grounded theory approach.

Results: Quantitative analyses yielded unexpected findings. Higher neighbourhood healthiness score was associated with children's lower diet quality (-0.040 points per unit, 95%CI: -0.073 , -0.006). Greater absolute fast-food outlet exposure was associated with better diet quality, but only among children with higher-educated mothers ($+0.021$ points per outlet, 95%CI: 0.008 , 0.034), suggesting socioeconomic buffering effects. Qualitative analysis illuminated these paradoxical patterns, revealing that parents' engagement with the neighbourhood food environment was relational and adaptive rather than a direct consequence of exposure. Perceptions of what was available, accessible, and acceptable evolved through everyday use, influenced by transport options, time, affordability, safety, and cultural fit. Many families extended their food networks beyond the neighbourhood via commuting routes or digital food retail, and selectively engaged with outlets that aligned with their values and resources.

Conclusion: Integrating both research methods reveals that the influence of neighbourhood food environments on children's diets depends on how families mobilise and make sense of local resources. Variability in these processes explains inconsistencies in quantitative, proximity-based models. This study demonstrates the value of combining spatial exposure metrics with lived-experience data to explain heterogeneity in dietary behaviours within local context.

II-P-G.38

Development of a New Program for After-school Care Staff to Promote Healthy Behaviours in Children

N. Toussaint¹, K. Sporrel², S. Mul¹, W. Scholtes-Bos², P.J. Weijs¹, M. Janssen¹, R.G. Fookink¹, M.T. Streppel¹

¹Amsterdam University of Applied Sciences, Amsterdam, Netherlands, ²The Hague University of Applied Sciences, The Hague, Netherlands

Purpose: After-school care is an important setting to foster healthy behaviours in school aged children. However, this promising role has not yet been extensively studied. Staff working in after-school care are often not specifically trained in promoting a healthy lifestyle and have expressed a need for practical tools to support healthy eating and physical activity behaviours across diverse groups of children. In this project, we develop, implement, and evaluate an innovative program for after-school care staff. The overall aim is to enhance staff practices related to eating and physical activity, as well as to improve the eating and physical activity behaviours in children at after-school care.

Methods: The program will be developed using the Intervention Mapping approach and through co-creation with after-school staff and school aged children. The first year of this project involves the development and the second year the implementation and evaluation of the program. The development phase includes 1) desk research; 2) interviews with staff and experts in healthy child development and childcare; 3) creative sessions with children, based on the mosaic approach; and 4) co-creation sessions involving both staff and children. In the implementation and evaluation phase, a pilot study will be conducted at 15 locations in the region of Amsterdam and The Hague, the Netherlands. Data for the process evaluation will be collected through interviews with staff and children and a questionnaire for staff. Observations before and after the program are part of the evaluation to explore the effects of the intervention.

Results: The results of the needs assessment with after-school care staff, school aged children, and experts in healthy child development and childcare will be presented. In addition, a prototype of the developed program will be introduced.

Conclusion: This project will deliver a practical, user-friendly, and widely applicable program to support after-school care staff in promoting healthy behaviours among children from diverse socioeconomic and sociocultural backgrounds.

Yáñez-Sepúlveda²², J.P. Zavala-Crichton²², M. Tremblay¹¹

¹University of Lethbridge, Lethbridge, Canada, ²Active Healthy Kids Global Alliance, Avignon, France, ³Instituto Nacional de Salud Pública, Cuernavaca, Mexico, ⁴University of Northern British Columbia, Prince George, Canada, ⁵Nepal Development Society, Kathmandu, Nepal, ⁶Obafemi Awolowo University, Ife-Ife, Nigeria, ⁷Universidad Pablo de Olavide, Seville, Spain, ⁸Mohammed Bin Rashid University Of Medicine and Health Sciences, Dubai, United Arab Emirates, ⁹Universidad de los Andes, Bogota, Colombia, ¹⁰Victoria University of Wellington, Wellington, New Zealand, ¹¹CHEO Research Institute, Ottawa, Canada, ¹²Karolinska Institutet, Huddinge, Sweden, ¹³University of Malawi, Zomba, Malawi, ¹⁴Palacký University Olomouc, Olomouc, Czech Republic, ¹⁵Mahidol University, Bangkok, Thailand, ¹⁶Hirabai Cowasji Jehangir Medical Research Institute, Pune, India, ¹⁷Shanghai University of Sport, Shanghai, China, ¹⁸Ambrose University, Calgary, Canada, ¹⁹Arizona State University, Phoenix, United States, ²⁰Federal University of Santa Catarina, Florianópolis, Brazil, ²¹University of Auckland, Auckland, New Zealand, ²²Universidad Andres Bello, Viña del Mar, Chile

Purpose: Active play is an important yet under-researched source of physical activity among children and adolescents. No previous study has compared active play levels assessed with a consistent measure across low-, middle-, and high-income countries. We explored the sociodemographic correlates of child- and parent-reported active play among 8- to 17-year-old participants in the Global Adolescent and Child Physical Activity Questionnaire (GAC-PAQ) pilot study.

Methods: In all participating countries, we recruited child-caregiver dyads (n=20 to 52) stratified by urbanicity and child sex. Participants and one of their caregivers completed the app-based GAC-PAQ, which includes a single-item assessing active play time in the past week. Children/adolescents reported their gender, and caregivers reported their child's sex. We categorized responses as >2 hours/day vs. ≤2 hours/day based on the Active Healthy Kids Global Alliance's benchmark. We categorized countries as low- and middle-income (LMICs) or high-income (HICs) based on the World Bank classification. We used generalized linear mixed models to assess sociodemographic factors associated with child- and caregiver-reported active play, controlling for child gender or sex (as appropriate), age, and country income classification.

Results: A total of 578 children/adolescents and 574 caregivers completed the questionnaire. Only 17.3% of children/adolescents reported engaging in >2 hours/day of active play (16.4% in LMICs and 18.8% in HICs). Based on caregiver report, 17.1% of participants met the >2 hours/day benchmark (14.5% in LMICs and 21.4% in HICs). Odds of engaging in active play for >2 hours/day decreased by about 10% for each year of age (child/adolescent-reported model: OR=0.90; 95% CI=0.83-0.98; caregiver-reported model: OR=0.88; 95% CI=0.81-0.96). Odds were lower among girls versus boys (OR=0.63; 95% CI=0.41-0.99).

Conclusion: If confirmed in future research, our findings suggest that more effort may be needed to promote active play, especially among girls and adolescents for whom it may be undervalued. Future research should further explore a broader range of correlates and assess the reliability and validity of our measure of active play among children, adolescents, and caregivers.

II-P-G.40

Intersecting Inequalities in Maternal and Child Nutrition: The Double Burden of Malnutrition in Colombian Households

Y.P. Rueda-Guevara¹

¹University of Pennsylvania, Demography and Sociology, Philadelphia, United States

Purpose: This study examines the social determinants associated with the Double Burden of Malnutrition in Colombian households.

G. CHILDREN AND FAMILIES

Methods: Using data from the 2010 and 2015 National Survey of Nutritional Situation (ENSIN), a representative, cross-sectional, multistage household survey covering the civilian population in urban and rural areas of all 32 departments. We conducted a cross-sectional descriptive analysis based on 8,580 mother-child pairs. The DBM was defined as the coexistence of a stunted child (height-for-age z-score < -2 SD) and an overweight or obese mother (BMI $\geq$ 25 kg/m²) within the same household. Socioeconomic and demographic variables were included to identify structural social determinants, such as household wealth quartile.

Results: The prevalence of DBM in Colombian households was estimated at 5.1%. Nearly half (49.3%) of households presented adequate nutritional status for both mother and child, while 45.6% showed mixed patterns of malnutrition. The DBM was more prevalent in rural areas (7.1%) than in urban areas (4.3%). A socioeconomic gradient was evident: prevalence decreased steadily from 6.3% in the poorest quartile to 3.0% in the wealthiest quartile. Regionally, Bogotá (6.9%) and the Pacific region (6.0%) exhibited the highest rates, compared with 3.8% in the Central region.

Conclusion: The findings highlight the intersection between social inequalities and nutritional outcomes in Colombia. The Double Burden of Malnutrition (DBM) reflects not only dietary transitions but also inequities in access to health, education, and economic resources. The social gradient observed, where DBM is concentrated among poorer, rural, and indigenous households, underscores the role of structural determinants such as wealth, education, and ethnicity. These results are consistent with studies in other middle-income countries, including Brazil, Mexico, and South Africa, where similar socioeconomic disparities shape DBM patterns.

II-P-G.41

Examining Physical Activity Progression among Latinx Youth: The Familias Activas Program

H. Garcia Cosavalente¹, R. Doig¹, A. Hurtado-Choque¹

¹University of Maryland, School of Public Health, Maryland, United States

Purpose: This study examined whether pre-test exercise habits predict post-test exercise levels among Latinx youth in a low-income county in Maryland, USA.

Methods: A multiple linear regression was conducted with pre-intervention hours of vigorous, moderate, and mild exercise of youth as predictors and post-intervention vigorous exercise hours as the dependent variable.

Results: The model was statistically significant, $F(3,19)=9.49$, $p<.001$, explaining 60% of the variance in post-intervention vigorous exercise ($R^2=.600$, adjusted $R^2=.537$). Among the predictors, pre-test mild exercise was the only significant contributor ($\beta=0.389$, $p=.010$), indicating that individuals who engaged in more mild exercise prior to the intervention tended to increase their vigorous exercise afterward. These findings suggest that mild exercise may play a key role in facilitating transitions to more vigorous activity among Latinx youth.

Conclusion: Results indicate that pre-test PA habits collectively explain a substantial proportion of the variance in post-test PA. However, among the predictors, only pre-intervention mild exercise significantly contributes to the increase in vigorous exercise after the intervention ($p=.010$). One limitation of the study is the small sample size ($N=23$); however, this outcome can shed light on the critical link between mild exercise and future vigorous activity among Latinx youth. Public health messages aimed at increasing physical activity might emphasize small, achievable steps (e.g., walking or jogging) as a first step toward adopting long-term vigorous exercise.

II-P-G.42

Effects of a Family Integrated Training Program (F.I.T Family) on Cardiorespiratory Fitness, Adiposity, and Psychosocial Outcomes among Children and Parents

S.H. Wong¹, W.Y. Huang^{2,3}, Z. Dai¹, C.H. Sit¹, M.C. Wong⁴, S.W. Wong⁵

¹The Chinese University of Hong Kong, Department of Sports Science and Physical Education, Shatin, Hong Kong, SAR of China, ²Hong Kong Baptist University, Department of Sports and Health Sciences, Academy of Wellness and Human Development, Kowloon, Hong Kong, SAR of China, ³Hong Kong Baptist University, Dr Stephen Hui Research Centre for Physical Recreation and Wellness, Kowloon, Hong Kong, SAR of China, ⁴The Chinese University of Hong Kong, The Jockey Club School of Public Health and Primary Care, Shatin, Hong Kong, SAR of China, ⁵Physical Fitness Association of Hong Kong, China, Kowloon, Hong Kong, SAR of China

G. CHILDREN AND FAMILIES

Purpose: Low physical fitness remains a significant concern among children in Hong Kong. While family-based interventions show promise, evidence of their effectiveness in culturally unique settings like Hong Kong is scarce. This study evaluated the impact of a Family Integrated Training (F.I.T. Family) program on cardiorespiratory fitness, adiposity, and psychosocial outcomes in Chinese children and parents.

Methods: In this two-arm, parallel, assessor-blinded randomized controlled trial conducted in Hong Kong from January 2023 to December 2024, 208 Chinese families (each consisting of one parent and their child aged 6–12 years) were randomly assigned in a 1:1 ratio to either the intervention or waitlist control group. The 15-week “F.I.T. Family” program included three parent-focused counseling sessions and twelve weekly, 60-minute practical sessions led by certified fitness instructors. Families were also prescribed a home-based exercise regimen to be completed three times per week, with 60 minutes per session. The control group maintained their usual routines. Primary outcomes included cardiorespiratory fitness and body composition in both children and parents. Secondary outcomes focused on psychosocial measures among parents.

Results: Of the 208 families randomized, 195 (93.8%) completed the study. After 15 weeks, the intervention group demonstrated significant improvements in cardiorespiratory fitness for both children ($\beta = 3.35$ PACER laps, 95% CI: 1.57, 5.13, $d = 0.70$, $p = 0.001$) and parents ($\beta = 3.43$ PACER laps, 95% CI: 1.72, 5.15, $d = 0.75$, $p = 0.001$) compared to controls. No significant between-group differences were observed in body composition. Parents in the intervention group reported significant improvements in psychosocial outcomes, including attitudes, intentions, enjoyment of physical activity, and certain domains of quality of life.

Conclusion: This 15-week family-integrated intervention improved cardiorespiratory fitness in both children and their parents, independent of changes in body weight status. Additionally, meaningful enhancements in psychosocial outcomes among parents were observed, highlighting the broader benefits of family-based approaches to health promotion. Future research with long-term follow-up is needed to assess the sustainability and generalizability of these effects across more diverse populations.

II-P-G.43

Barriers and Facilitators to Outdoor Play among Filipino Children

Z.R.T. Brebante¹, E.-Y. Lee², J.Y. Cagas³, W.Y. Huang^{1,4}

¹Hong Kong Baptist University, Department of Sports and Health Sciences, Kowloon, Hong Kong, SAR of China, ²Yonsei University, Department of Sport Industry Studies, Seoul, Korea, Republic of, ³University of the Philippines Mindanao, Department of Human Kinetics, Davao, Philippines, ⁴Hong Kong Baptist University, Dr Stephen Hui Research Centre for Physical Recreation and Wellness, Kowloon, Hong Kong, SAR of China

Purpose: Outdoor play is essential for childhood development, enhancing physical, mental, and social well-being. Yet, global participation in outdoor play is declining for various reasons. In the Philippines, prior research has identified high population density in urban areas and insufficient infrastructure as significant obstacles to access to and participation in outdoor play. However, factors affecting participation in rural areas have not been well-explored. Thus, this pilot study aims to identify the challenges and facilitators of outdoor play among Filipino children in rural areas. Understanding the role of outdoor play in these communities is essential for developing effective practices and policies that promote healthier, more active lifestyles in diverse cultural contexts.

Methods: A qualitative approach using semi-structured face-to-face focus groups and individual interviews was employed. Eleven children aged 8-15 years (6 boys, 5 girls) from a rural region in Mindanao participated through snowball sampling. Parental consent was obtained. Data were transcribed verbatim and analyzed using thematic analysis.

Results: The themes identified among the barriers to outdoor play include weather conditions, safety concerns, parental restrictions, and competing demands, such as increased screen time, busy schedules, other responsibilities, and fatigue. Conversely, themes such as encouragement from both parents and friends, the accessibility and availability of open spaces, and being with others were identified as facilitators of outdoor play.

Conclusion: The study highlights the critical challenges and facilitators of outdoor play among Filipino children in rural areas. Addressing these barriers to outdoor play while enhancing facilitators may promote healthier lifestyles and holistic development, and support effective policies that encourage outdoor engagement, fostering community well-being across diverse cultural settings. Future direction may also emphasize the need to understand how different cultural contexts define outdoor play and the importance of enhancing children’s awareness of its role and significance.

G. CHILDREN AND FAMILIES

Parental Perceived Barriers for Preschoolers' Physical Activity and Children's Physical Activity from Preschool to School Age; A Six-year Follow-up Study

C. Ray^{1,2}, M. Maukonen^{3,4,1}, J. Kailaheimo-Björkqvist¹, H. Vepsäläinen², J. Kesäläinen⁵, R. Lehto^{2,1}, N. Serasinghe^{2,1}, T. Sarvanne^{2,1}, J. Rahkola¹, H. Launistola^{6,1}, E. Roos¹

¹Folkhälsan Research Center, Public Health Research Programme, Helsinki, Finland, ²University of Helsinki, Department of Food and Nutrition, Helsinki, Finland, ³University of Tampere, Department of Social Sciences, Tampere, Finland, ⁴Finnish Institute for Health and Welfare, Helsinki, Finland, ⁵University of Eastern Finland, Joensuu, Finland, ⁶University of Helsinki, Faculty of Medicine, Helsinki, Finland

Purpose: Evidence on associations between parental perceived barriers and preschool age children's physical activity (PA) is mixed. Less is known about whether parental perceived barriers during preschool age are linked to PA in school age. We examined cross-sectional associations between parental perceived barriers and preschooler's PA, and whether the barriers for PA at preschool age associated with children's PA six years later.

Methods: DAGIS intervention study was conducted among 3-6 years-old in preschools in Salo, Finland in 2017-2018 (analytic sample n=447) with a six-year follow-up carried out in 2023-2024, children 9-12 years-old (analytic sample n=119). Intensity of PA was measured during 7 days by accelerometers (Actigraph wGT3X-BT). Light PA (LPA), moderate-to-vigorous (MVPA), and total PA were used as continuous variables in analysis. Parental perceived barriers for children's PA was asked from parents by 7 items rated on a three-point scale (1 = not a barrier, 2= a barrier to some extent 3 = a barrier to a great extent). A composite mean score was computed for barriers (mean 1.41, SD 0.30), showing modest internal consistency (Cronbach's $\alpha = 0.64$). Linear regression analyses adjusted for child's age, sex, and parental educational level were used to examine cross-sectional associations between perceived barriers and preschool children's PA. Longitudinal associations between preschool barriers and school age children's PA were further adjusted for baseline PA and preschool intervention status.

Results: Higher parental perceived barriers for children's PA were associated with lower LPA (B -10.1; 95% CI -19.0; -1.29), MVPA (B -10.5; 95% CI -15.7; -5.32), and total PA (B -20.7; 95% CI -32.5; -8.84) at preschool age. In the longitudinal analysis higher parental perceived barriers in preschool was associated with lower total PA (estimate B: -45.1, 95% CI -88.4; -1.72), but not with LPA or MVPA at school age.

Conclusion: Higher parental perceived barriers to children's PA were associated with lower PA in preschool and with lower total PA six years later. Parental perceived barriers to children's PA appear to be an important determinant of children's PA at school age and should be addressed in early childhood.

II-P-G.45

Understanding Food Insecurity among Families in Flanders, Belgium: The School as a Supportive Setting

E. Denys¹, A.-S. Van Dijck¹, D. Van de Sompel², C. Dijkstra³, N. Maertens⁴, W. Van Lippevelde¹

¹Ghent University, Department Marketing, Innovation and Organisation, Ghent, Belgium, ²Ghent University, Department Communication Studies, Ghent, Belgium, ³Amsterdam UMC, Department Public and Occupational Health, Amsterdam, Netherlands, ⁴Ghent University, Ghent, Belgium

Purpose: Food insecurity significantly affects children's dietary quality, health, and well-being, even in high-income settings, such as Flanders, Belgium. While qualitative research has extensively examined the lived experiences of food-insecure families in countries such as the United States, research in Europe remains scarce. Moreover, the perspectives of both parents and children are rarely integrated into strategies addressing food insecurity. In addition, limited research has examined how schools can respond to the needs of food-insecure families. This study aimed to (1) explore factors influencing the ability of food-insecure families in Flanders to provide sufficient, healthy, culturally and socially appropriate foods for their children, and (2) examine how the school environment can respond to these needs.

Methods: A qualitative study combining individual and focus group interviews was conducted in two Flemish municipalities in which participants were recruited through local social organizations. First, individual face-to-face interviews were conducted with five parents and two primary school-aged children. Second, two focus groups were organized within pre-existing parent groups linked to those social organizations. In addition, participating parents completed a socio-demographic questionnaire. All qualitative data were analyzed using reflexive thematic analysis,

G. CHILDREN AND FAMILIES

combining inductive and deductive coding strategies.

Results: Six overarching themes emerged. Three themes described individual and structural factors shaping food provision within the family context: (1) physical availability and accessibility of food, including limited cultural appropriateness and mobility constraints; (2) financial accessibility, with parents prioritizing quantity over quality due to high food prices; and (3) individual coping strategies, with parents consistently prioritizing their children's needs and preferences despite limited resources. Three additional themes reflected the school's potential supportive role: (4) as a structural and responsive food provider; (5) as a financial and material supporter; and (6) as a partner in food education.

Conclusion: Food insecurity among families in Flanders is shaped by interacting structural and individual dynamics within the broader food environment. Schools emerge as key settings with the potential to address nutritional inequalities through food provision, financial support, and educational engagement. These findings highlight the need for systemic, context-sensitive approaches that integrate the lived experiences of food-insecure families to ensure acceptability and effectiveness of support initiatives.

II-P-G.46

Machine Learning Applied to Analyzing How Multidimensional Variables Affect Cognitive Performance in a School-based Physical Activity Intervention

J. Ywagne¹, J. Tejada², J.C.N. Melo³, D. Ohara⁴, J.A. Brito⁵, G.M. Jesus⁶, L.A. Dias⁷, A.K.C. Silva⁸, L.G.O. Luz⁹, D.R.P. Silva¹⁰

¹Federal University of Sergipe, Health Sciences Graduate Program, São Cristóvão, Brazil, ²Federal University of Sergipe, Department of Psychology, São Cristóvão, Brazil, ³University Estadual de Londrina, Graduate Program in Health Sciences, Londrina, Brazil, ⁴State University of Santa Cruz, Department of Health Sciences, Ilhéus, Brazil, ⁵Southwest Bahia State University, Department of Health, Jequié, Brazil, ⁶State University of Feira de Santana, Department of Health, Postgraduate Program in Public Health, Feira de Santana, Brazil, ⁷Federal University of Western Bahia, Center for Biological and Health Sciences, Barreiras, Brazil, ⁸Federal University of Pernambuco, Department of Physical Education, Recife, Brazil, ⁹Federal University of Alagoas, Laboratory of Physical Activity and Health in Children and Adolescents (LACAPS), Arapiraca, Brazil, ¹⁰Federal University of Sergipe, Department of Physical Education, São Cristóvão, Brazil

Purpose: Cognitive development in primary schools is influenced by multiple interacting variables at different levels, which are rarely fully controlled in physical activity intervention studies. As a result, small or indirect effects may go undetected when traditional statistical approaches are used. This study applies a machine learning metric, feature importance, to examine the relative contribution of variables from different dimensions to cognitive development.

Methods: The data derive from a cluster-randomized controlled clinical trial. The “ERGUER NORDESTE” project includes 770 first- and second-grade elementary school children, aged 7 to 9 years (54% girls), from four cities across three states in Northeast Brazil. Each city includes three intervention groups (physical activities lessons, physical active breaks and control group). Feature importance from different machine learning models (C5.0, SVM, BART, EARTH, and Random Forest) was extracted after training the models to classify children's performance on five tests assessing executive functions (working memory, behavioral inhibition, selective attention, and cognitive flexibility). Feature importance scores were scaled from 0 to 100 to indicate the relative contribution of each variable to the model. The primary predictor is assigned a value of 100, meaning that a feature with a score of 50 has half the importance of the primary predictor in the final prediction. Predictors included cities, schools, intervention groups, self-reported quality of life questionnaire scores, daytime sleepiness, and food consumption (preprocessed using Principal Component Analysis with variable reduction, considering the first five components). All analyses were performed in R.

Results: Across all five machine learning models, school was the most important predictor of cognitive performance, ranking first in the EARTH, BART, C5.0, and Random Forest models (all = 100.0) and second in SVM (83.3), in which healthy food consumption ranked first (100.0). Unhealthy food consumption demonstrated high importance in EARTH (69.4), SVM(100.0), and Random Forest (83.5). Healthy food consumption was also highly relevant in Random Forest (84.3) and C5.0 (50.8). Other variables showed lower importance in the models.

Conclusion: Machine learning models consistently identified school context and healthy food consumption and unhealthy food, as the main contributors to cognitive performance.

II-P-G.47

From Complexity to Clarity: A Structured Framework for Translating Large-scale Multidimensional Data into Child-appropriate Feedback Reports in the ReDiKid Study

J. Vindis¹, D. Janda¹, T. Juricova¹, J. Pelclova¹

¹Palacký University Olomouc, Faculty of Physical Culture, Olomouc, Czech Republic

Purpose: Large-scale behavioral studies involving children generate extensive and heterogeneous datasets (e.g., questionnaires, accelerometry, anthropometric measures, motor tests). However, systematic approaches for reducing and translating such data into simple, age-appropriate, and child-understandable feedback remain limited. The purpose of this study was to develop and describe a structured framework that enabled the creation of an individual, comprehensible feedback report for child participants within the “Resilient Child in the Digital World” (ReDiKid) study.

Methods: The framework for developing feedback reports was created using pilot data from 309 children aged 9–11 years, including heterogeneous data from questionnaires, accelerometry, and physical fitness tests. Development followed six systematic steps: (1) selection of four domains and key indicators from the full dataset; (2) conversion of different data formats (e.g., minutes, scores, percentiles) into a common evaluation system; (3) transformation of results results onto a five-level visual rating scale; (4) development of a graphic and communication structure of the report emphasizing clarity and age appropriateness; (5) construction of a binary domain model enabling overall narrative feedback across domains; and (6) automation of report generation in R.

Results: The framework enabled systematic reduction of data derived from more than 20 research instruments into four coherent domains (resilience, digital behavior, movement behavior, health and lifestyle) and 12 key indicators, which were translated into simple and child-understandable feedback. Heterogeneous data types (e.g., minutes of physical activity, motor test performance, percentiles of questionnaire scores) were unified into a single five-level visual scale, allowing interpretation without reference to raw values. The binary domain model generated 16 distinct overall evaluation profiles, each associated with tailored, positively framed feedback and a corresponding visual avatar, transforming multidimensional data into a coherent and child-understandable overall message. The fully automated system generates individualized PDF reports and is prepared for the main data collection involving approximately 1,500 children.

Conclusion: The proposed framework provides a structured and scalable approach for translating complex multidimensional data into child-appropriate feedback. It offers a practical model for communicating research findings to children and can be extended to adapted feedback formats for parents.

II-P-G.48

What is Needed to Increase Effectiveness and Reach of the NHS Healthy Start Scheme in England: Inclusive, Positive Framing and Appropriate Support to Apply

M. Barrett^{1,2}, K. Campos¹, S. Clohessy¹, C. Vogel^{1,2}

¹City St George's University of London, Centre for Food Policy, London, United Kingdom, ²University of Southampton, Medical Research Council Lifecourse Epidemiology Centre, Southampton, United Kingdom

Purpose: Healthy Start (HS) is a UK government food subsidy programme for low-income families that aims to increase consumption of healthy foods. HS is accessed by only ~63% eligible people. Previous research showed eligible families are not accessing HS because of difficulties signing up and misconceptions about the scheme. This study sought to identify: 1a) How HS could be worded or ‘reframed’ to be more inclusive and reach more families, and 2) How to provide the ‘helping hand’ that families need to sign-up to HS?

Methods: Semi-structured interviews were conducted online with stakeholders including families eligible for HS, health professionals, local government officials, and advocacy organisations across England. Purposive sampling was used to gather rich and contextual data against the research questions. Reflexive thematic analysis was applied and interview transcripts coded using NVivo software.

Results: Data from n=45 participants identified that HS could reach more families if words used to describe it consider the breadth of families’ cultural beliefs and values. Words that focus on personal empowerment, the health benefits of eating well, improvements to families’ economic agency, and positive parenting are likely to resonate more widely. Professionals could support families to sign-up by encouraging them to ‘Just give it a go’ rather than

G. CHILDREN AND FAMILIES

describing complex eligibility criteria. To highlight the importance of HS for families experiencing food insecurity to policymakers, using terms like justice and equity, adopting a lifecourse approach to nutrition, and aligning with policy goals are impactful approaches.

Families want and need a 'helping hand' to apply for HS, leading the process with support from trusted people in locations they consider 'safe spaces'. These spaces are not always health clinics/ formal settings, but informal community spaces where families spend time. Who offers the 'helping hand' is important and many families trust and learn most from parents like them, with similar life experiences.

Conclusion: This study highlights the importance of words used to describe food subsidy schemes to enable all eligible families to engage and benefit. Ensuring appropriate support to navigate the registration process from trusted people supports wider community empowerment among groups who may be missing out on essential services.

II-P-G.49

Accuracy of a Simple and Scalable Tool for Estimating Body Composition in Arab Adolescents

S. Aljassar¹, L. Nasreddine², E.-J. Fares², M. Taktouk², H. Ahmad³, K. Hammad³, R. Barham⁴, C. Loechl⁵, M. Hudda⁶, K. Weston¹, J. Reilly¹

¹University of Strathclyde, Glasgow, United Kingdom, ²American University Beirut, Beirut, Lebanon, ³Atomic Energy Commission, Damascus, Syrian Arab Republic, ⁴Ministry of Health, Amman, Jordan, ⁵IAEA, Vienna, Austria, ⁶Dasman Institute, Kuwait, Kuwait

Purpose: Accurate assessment of body fatness is important for behavioral nutrition and physical activity research, yet many methods are time- and resource-intensive and inaccurate. The Hudda et al equation, originally developed in a UK population of children and adolescents and thereafter externally validated in more than 20 childhood settings globally, accurately estimates fat mass (FM) using only weight, height, age, sex, and ethnicity. The equation has not yet been validated in Arab adolescents. We aimed to validate the equation accuracy in Arab adolescents, using total body water-measured fatness from deuterium dilution (DD) as a reference method.

Methods: Data were obtained from 240 adolescents (58% boys), age 14-15 years old from Jordan, Lebanon, and Syria. Accuracy was assessed by comparing predicted FM with DD-measured FM using R², calibration slope, calibration-in-the-large (CITL), root mean square error (RMSE), and Bland-Altman analysis.

Results: R², calibration slope, and CITL were 82% (CI: 78% to 86%), 1.00 (95% CI: 0.94 to 1.06), and 1.3kg (CI: 0.8 to 1.8kg), respectively, with RMSE of 4.1 kg. Bland-Altman analysis showed a mean bias of 1.3 kg (95% CI: 0.8 to 1.8kg), with wide limits of agreement of -6.4 to 9.0 kg.

Conclusion: The prediction equation showed modest accuracy, though country-specific recalibration may further improve its performance in the future. Our data suggest that predicting body composition from simple, easily collected, data is a promising approach for nutrition and physical activity research and public health surveillance. Nonetheless, our findings indicate that the prediction accuracy is currently more acceptable at the group level rather than the individual level.

II-P-G.50

Healthful vs. Unhealthful Plant-based Diets During Pregnancy: Nutritional Adequacy and Intake of Plant-based Analogs and Ultra-processed Foods

P. Grégory¹, C.Y. Benrabah¹, E. Kesse-Guyot¹, J. Baudry¹, S. Péneau¹, M. Touvier¹, L. Fézeu¹, B. de Lauzon-Guillain¹, V. Moullé², P. Parnet², B. Allès¹

¹Université Sorbonne Paris Nord and Université Paris Cité, INSERM, INRAE, CNAM, Centre for Research in Epidemiology and Statistics (CRESS), Nutritional Epidemiology Research Team (EREN), Bobigny, France, ²Nantes Université, INRAE, UMR 1280, PhAN, IMAD, Nantes, France

Purpose: Plant-based diets (PBD), which could be beneficial for both the environment and health, should also ensure adequate nutrient intakes, especially during critical stages of life such as pregnancy. Ultra-processed foods (UPFs, NOVA4), including some plant-based animal products analogs, should be consumed moderately to prevent future adverse health effects both in pregnant women and offspring. Our aim was to test associations between adherence to healthful and unhealthful PBD and nutritional adequacy among pregnant women. We also examined non-UPFs

G. CHILDREN AND FAMILIES

(NOVA1), UPFs and plant-based analogs consumption.

Methods: This study included 3,785 women who declared a pregnancy during their follow-up in the French web-based NutriNet-Santé study. Daily food intakes were collected using repeated 24-h dietary records. Foods were categorised according to their level of processing using NOVA classification and, if applicable, in plant-based analogs groups. For each participant, we assessed their nutritional adequacy by computing Probability of Adequate Nutrient Intake score (PANDiet) adapted to updated recommendations for French pregnant women, and adherence to healthful and unhealthful PBD using healthful and unhealthful PBD indices (hPDI and uPDI).

Means of PANDiet score and UPFs, UnPFs, and analogs intakes were compared across hPDI and uPDI quartiles, adjusted for age and EI.

Results: Pregnant women with highest adherence to healthful PBD (4th hPDI quartile) had a slightly better nutritional adequacy ($\Delta_{Q4-Q1, PANDiet} = 2.3$, $p < 0.0001$) and slightly higher non-UPFs intakes ($\Delta_{Q4-Q1, non-UPFs} = 4.7\%$, $p < 0.0001$), compared to women with lowest adherence level (1st hPDI quartile). On the contrary, those with highest adherence level to unhealthful PBD had a lower nutritional adequacy and non-UPFs contribution (all $p < 0.001$). Regarding analogs, both 4th hPDI and uPDI quartiles had a higher plant-based beverages consumption (7.1% consumers with a mean intake of 96 mL/d, all $p < 0.001$).

Conclusion: Pregnant women who adhered the most to healthful plant-based diet had a better diet quality, considering nutritional adequacy and unprocessed foods contribution as quality indicators. A few of them consumed plant-based analogs, with moderate intake. Further epidemiological studies are needed to test a potential effect of a nutritionally-balanced PBD for both women and children during early life days.

II-P-G.51

Longitudinal Associations between Parent Child Technology Interference and Cognitive and Social Emotional Development in Early Childhood

R. Martins¹, M. Boyd¹, S. Wiebe¹, C. Rinaldi¹, Y. Zheng¹, J. Rai¹, M. Potter¹, J. Li¹, K. Dorn¹, V. Carson¹

¹University of Alberta, Edmonton, Canada

Purpose: Parent-child technology interference refers to technology (e.g., smartphone, TV) related interruptions to shared interactions and may undermine the responsive caregiving processes that support early executive function, language, and self-regulation development. However, evidence to date is largely cross-sectional. The purpose of this study is to examine longitudinal associations between parent-child technology interference and cognitive and social-emotional development across the preschool years.

Methods: Participants were 360 parents and their preschool-aged children (3.0, 3.5, or 4.0 years at baseline) recruited in Western Canada as part of the TECHnology and Development in Early Childhood (TECH) project. Participants were followed over 12 months with assessments at baseline, 6 months, and 12 months (October 2022 to November 2024). Frequency of daily parent-child technology interference was assessed at each wave using an adapted 6-item Technology Device Interference Scale covering common devices (score range 0 to 36). Child cognitive outcomes were assessed at each wave via virtual administered games, including response inhibition (Head Toes Knees Shoulders), working memory (forward and backward word span), self-control (Snack Delay), and expressive vocabulary (Early Years Toolbox). Social-emotional development was assessed by parent-reported self-regulation (Child Self Regulation and Social Behaviour Questionnaire) and behavioural strengths and difficulties (Strengths and Difficulties Questionnaire at 6 and 12 month follow-up). Longitudinal associations will be estimated using Linear Mixed Models with random intercepts for time (i.e., age centered). Technology interference will be treated as a time varying exposure. Models will be adjusted for children's sex, race/ethnicity, and non-parental care time as well as parental education, marital status, and stress.

Results: Analyses will estimate associations between parent-child technology interference and each developmental outcome over time, reporting fixed effect estimates with 95 percent confidence intervals. Model diagnostics will evaluate residual assumptions, influential observations, and multicollinearity. Effect sizes and model fit indices (marginal and conditional R^2 , information criteria) will be reported.

Conclusion: This study extends prior cross-sectional evidence by testing whether technology related interruptions in parent-child interactions are longitudinally associated with preschool cognitive and social-emotional development. Findings will inform guidance and intervention targets aimed at supporting responsive caregiving and healthy early development in increasingly digital family environments.

G. CHILDREN AND FAMILIES

II-P-G.52

More Streaming, More Energy Drinks: Links between Livestream Viewing and Beverage Intake in U.S. Adolescents

C. Millward¹, H. Hopfer², F. Dardis³, M. Failla², T. Masterson¹

¹The Pennsylvania State University, Nutritional Science, State College, United States, ²The Pennsylvania State University, Food Science, State College, United States, ³The Pennsylvania State University, Advertising and Public Relations, State College, United States

Purpose: Livestreaming has become an increasingly common way to consume social media content, particularly for adolescents aged 13-17 years. Livestreaming involves the live creation of video content for social media. Two of the most marketed food products on livestreaming platforms are soda and energy drinks, both a major source of added sugars, caffeine, and other stimulatory products known to have detrimental effects on adolescent health. These products are often marketed to adolescents on these streaming platforms as “energy promoting” and “performance-enhancing.” Understanding how media engagement (livestreaming behavior) impacts beverage consumption patterns may help inform regulatory and counter-marketing strategies. Here, we examined associations between daily streaming time and beverage intake frequency among adolescents.

Methods: Adolescents aged 13–17 years (n = 1,471) were recruited nationwide through an online panel. Participants self-reported daily streaming time (0–2, 3–4, or ≥5 hours/day) and intake frequency of water, milk, soft drinks, and energy drinks (less than once/week, 2–6 times/week, once or more/day). Chi-square tests assessed associations between streaming category and beverage intake. Percentages reflect intake distribution within streaming groups.

Results: Streaming time was significantly associated with intake patterns for water, soft drinks, and energy drinks, but not for milk. Higher streaming time was associated with lower water consumption ($\chi^2 = 21.19$, $p < 0.01$), higher soft drink intake ($\chi^2 = 47.19$, $p < 0.01$), and higher energy drink consumption ($\chi^2 = 104.97$, $p < 0.01$). Milk consumption did not differ by streaming level ($\chi^2 = 7.31$, $p = 0.121$). High streamers (>5 hours/day) were more likely to consume energy drinks at least once daily (23.3%), compared to moderate (3-4 hours/day) (14.9%) and low (0-2 hours/day) streamers (9.1%).

Conclusion: Greater self-reported livestreaming viewing was associated with higher consumption of both energy drinks and soft drinks, and with lower water intake. The association between increased livestream use and energy drink consumption is consistent with the large amount of energy drink marketing found on livestreaming social media. Interventions aimed at reducing adolescent exposure to marketing of energy-dense beverages on digital media platforms may support healthier beverage choices.

II-P-G.53

Social Support, Autonomous Motivation, Self-efficacy, and Physical Activity among 10- to 14-Year-old Adolescents: A Cross-sectional Study

L. Robbins¹, N. Fraczek², H. Varpaai¹, K. Arcoleo¹, K. Clevenger³, J. Ling¹

¹Michigan State University, College of Nursing, East Lansing, MI, United States, ²Michigan State University, College of Education, East Lansing, MI, United States, ³Utah State University, Emma Eccles Jones College of Education and Human Services, Logan, UT, United States

Purpose: Globally, 81% of adolescents are physical inactive. In the U.S., only 24% of high school adolescents are meeting recommendations calling for 60 minutes of moderate-to vigorous physical activity (MVPA) daily. These dismal percentages underscore a need to examine relationships between various psychosocial factors and not only MVPA but also light physical activity (LPA), while understanding the influence of demographic, physiological, and activity-related characteristics. LPA warrants consideration in research with adolescents because it has been associated with improvements in cardiometabolic biomarkers and long-term physical activity (PA) participation. To contribute toward addressing this gap, two aims of this study were to: investigate relationships between psychosocial factors (autonomous motivation for PA, PA self-efficacy, social support for PA) and PA intensities (LPA and moderate [MPA], vigorous [VPA], and MVPA) among adolescents (ages 10-14) in the U.S.; and (2) examine the influence of demographic, physiological, and activity-related characteristics (age, sex, race/ethnicity, body mass index [BMI], annual family income, cardiorespiratory fitness [CRF; estimated maximal oxygen uptake: $\text{VO}_2 \text{ max}$], current sports or cheerleading team participation, and non-sport PA program participation) on various PA intensities.

Methods: This cross-sectional study involved a secondary analysis of data from a large-scale randomized controlled

G. CHILDREN AND FAMILIES

trial. In 2022-2024, adolescents completed demographic and psychosocial surveys and wore accelerometers to assess PA. Of 935 adolescents enrolled, 623 (66.6%) had valid accelerometer data (≥ 4 days). Structural equation modeling was used for analysis.

Results: MPA, VPA, and MVPA were positively associated with male sex, higher CRF, and sports or cheerleading team participation. Age and BMI z-score were negative predictors of MVPA and VPA. MPA was negatively associated with age, and light PA was negatively associated with annual family income. Social support for PA predicted both autonomous motivation for PA and PA self-efficacy. Indirect effects of social support on the various levels of PA intensity via autonomous motivation or PA self-efficacy were not significant.

Conclusion: Increasing social support for PA may enhance adolescents' autonomous motivation for PA and PA self-efficacy. However, indirect effects on the PA intensity levels were not statistically significant, underscoring the promise and limitations of psychosocial pathways and the need for continued research.

H. POLICIES AND ENVIRONMENTS

Temporal Trends in Neighborhood Access to Daily Destinations across 12 Spanish Cities (2014–2024)

A. Colom¹, X. Delclòs-Alió², M. Domínguez³

¹Research Group in Nutritional Epidemiology and Cardiovascular Physiopathology (NUTRECOR), Health Research Institute of the Balearic Islands (IdISBa), Palma, Spain, ²Grup de Recerca en Anàlisi Territorials i Estudis Turístics (GRATET), Departament de Geografia, Facultat de Turisme i Geografia, Universitat Rovira i Virgili, Vila-seca, Spain, ³Geographic Information Systems and Remote-Sensing Service - SSIQT, University of the Balearic Islands, Palma, Spain

Purpose: In a context in which public policies are investing in the promotion of creating more livable environments. The purpose of this study was to examine temporal trends in neighborhood access to daily destinations across multiple Spanish cities between 2014 and 2024. Specifically, we aimed to quantify how mean access to daily destinations index, and its components evolved over time within and between cities, identifying whether urban environments became more or less supportive of walking during this period.

Methods: We conducted a longitudinal ecological analysis of neighborhood access to daily destinations across 12 geographically diverse Spanish cities from 2014 to 2024. Access to daily destinations was quantified annually within 100 × 100 m grid cells following the Global Healthy and Sustainable City Indicators Software, an open science toolkit. A composite daily living index was calculated summing equal-weighted access scores on three objective indicators derived from geospatial data at the neighborhood level: healthy food market, a convenience store, and a public transport stop within 500 m.

To enable temporal and intercity comparisons, daily living index values were standardized as z-scores using the global mean and standard deviation of all observations across cities and years. For each city and year, we computed the mean daily living index and its corresponding 95% confidence interval (95% CI).

Results: Mean access to daily destinations increased progressively from −0.18 (95% CI: −0.33, −0.02) in 2014 to 0.20 (0.06, 0.33) in 2024, reflecting a steady improvement in local accessibility to essential amenities across Spanish cities. Gains were more pronounced in large metropolitan areas such as Barcelona, Málaga, and Sevilla, whereas smaller or less dense cities (e.g., León, Jaén) exhibited modest yet consistent growth. Among the components, access to public transport stops remained the highest and most stable contributor (increasing slightly from 0.80 to 0.83); convenience stores showed marked growth across nearly all cities (from 0.32 to 0.46); and healthy food markets persisted as the most limited and spatially unequal resource (from 0.33 to 0.53).

Conclusion: This study provides a standardized, spatially and temporally comparable framework to monitor changes in neighborhood access to daily destinations across Spanish cities over the past decade.

I-P-H.02

Five-year Evolution of the Overall Nutritional Quality of Local and Non-local Breads and Processed Meats Offered and Sold in the Province of Québec (Canada)

J. Fournier^{1,2}, M. Turcotte², A. Corriveau², M.-È. Labonté^{1,2}

¹Université Laval, Faculty of Agriculture and Food Sciences, School of Nutrition, Québec, Canada, ²Université Laval, Institute of Nutrition and Functional Foods (INAF), Centre Nutrition, Santé et Société (NUTRISS), Québec, Canada

Purpose: Assessing changes in the nutritional quality of the food supply is essential to understand how it evolves over time, to ultimately support its improvement. The lack of sales data is often reported as a limitation in food supply studies. This study aims to evaluate the five-year evolution of the overall nutritional quality of both local and non-local prepackaged foods in the province of Québec (Canada), by integrating food supply and food sales data.

Methods: Two food categories were studied using the Food Quality Observatory's database: sliced processed meats ($n_{2017-2018}=361$; $n_{2022}=487$) and sliced breads ($n_{2016-2017}=294$; $n_{2021}=340$). Local foods were defined as those produced and/or processed in Québec and those with at least one "Aliments du Québec" logo on the package. Overall nutritional quality was measured using the 2017 Nutri-Score (NS) nutrient profiling algorithm, in which a lower score reflects a better nutritional quality. Wilcoxon rank sum tests were used for unweighted comparisons (food supply) and rank regressions were used for sales-weighted comparisons.

Results: Unweighted results indicate that overall nutritional quality deteriorated over five years in the whole category of meats ($NS_{2017-2018}=12.6\pm 7.6$ vs. $NS_{2022}=13.8\pm 7.8$, $p=0.02$), in meats specifically produced and/or processed outside of

H. POLICIES AND ENVIRONMENTS

Québec (12.2 ± 8.0 vs. 13.8 ± 8.2 , respectively, $p=0.04$), and in those without an “Aliments du Québec” logo (12.7 ± 7.7 vs. 14.1 ± 7.9 , $p=0.015$). The overall nutritional quality of breads remained similar over time ($NS_{2016-2017} = -0.9 \pm 3.3$ vs. $NS_{2021} = -0.4 \pm 3.5$, $p=0.06$), but deteriorated in breads without a logo (-0.7 ± 3.4 vs. 0.1 ± 3.5 , $p=0.015$). Conversely, sales-weighted results show that overall nutritional quality improved over time in both food categories as a whole (meats: 13.4 ± 5.9 vs. 12.1 ± 6.8 ; breads: 0.2 ± 3.0 vs. 0.1 ± 2.9 , both $p=0.02$), and in foods specifically produced and/or processed in Québec (meats: 13.7 ± 5.5 vs. 11.5 ± 6.4 ; breads: -0.1 ± 3.0 vs. -0.2 ± 2.8 , both $p=0.001$).

Conclusion: While the overall nutritional quality of some foods available on the market deteriorated over time, sales-weighted data revealed an overall improvement, particularly for foods locally produced and/or processed. Such contrasting results highlight the importance of taking consumer purchases into account in food environment assessments. Further research should explore other food categories.

I-P-H.03

Comparison of the Overall Nutritional Quality of Prepackaged Foods Available in Quebec, Canada, with and without Sugar Claims

K. Terrault^{1,2}, A. Corriveau², L. Vanderlee^{1,2}, M.-È. Labonté^{1,2}

¹Université Laval, Faculty of Agriculture and Food Sciences, School of Nutrition, Québec, Canada, ²Université Laval, Institute of Nutrition and Functional Foods (INAF), Centre Nutrition, Santé et Société (NUTRISS), Québec, Canada

Purpose: Food products labelled as sugar-reduced or sugar-free may be appealing to consumers, but little is known about the overall nutritional quality of such products. This project aims to assess the overall nutritional quality of prepackaged foods offered in Quebec, Canada, according to the presence or absence of sugar claims, at two different time points.

Methods: Nutritional composition data were obtained from the Food Quality Observatory, located in Quebec City, Canada. Preliminary analyses were performed with yogurts and dairy desserts, collected in 2018 ($n=548$) and 2023 ($n=387$). Overall nutritional quality was determined using the Nutri-Score algorithm (NS; 2017 version). A lower NS score reflects a better nutritional quality. The presence of sugar claims was determined using on-package information, according to Health Canada’s regulations. Wilcoxon rank-sum tests were performed ($\alpha=0.05$).

Results: Yogurts and dairy desserts carrying any type of sugar claim had a lower NS score than products without claims in both data collections (2018: -1.36 ± 1.76 vs. 1.42 ± 3.26 , respectively, $p<0.0001$; 2023: -0.49 ± 1.55 vs. 1.36 ± 3.28 , $p<0.0001$). Similarly, products carrying the “no added sugars” claim had a lower NS score than products without such claim, again in both data collections (2018: -1.46 ± 1.18 vs. 1.29 ± 3.26 , respectively; 2023: -1.40 ± 1.57 vs. 1.32 ± 3.20 , both $p<0.0001$). In 2018 only, products specifically carrying the “lower in sugars” claim had lower NS score than products without that claim (-4.17 ± 0.98 vs. 1.10 ± 3.20 , respectively, $p<0.0001$).

Conclusion: These preliminary results suggest that sugar claims may be an indicator of a better overall nutritional quality in yogurts and dairy desserts, especially with the “no added sugars” and “lower in sugars” claims. Similar analyses in other widely consumed food categories prone to display sugar claims (e.g., granola bars, dairy and plant-based beverages, cookies) are warranted to assess whether similar findings emerge. This project will enable a comprehensive and rigorous assessment of the accuracy of sugar claims, in addition to the indirect effects of public health initiatives that encourage the reduction of sugar content in products.

I-P-H.04

From Policy to Practice: School Nutrition Directors’ Views on Emerging Added Sugar, Sodium, and Synthetic Dye School Meal Standards

E. Adams¹, M. Bean², R. Figueroa³, J. Cohen⁴, M. Gombi-Vaca⁵, M. Savidge¹, A. Brantley¹, R.G. Weaver¹, M. Beets¹, S. Burkart¹, B. Armstrong¹

¹University of South Carolina, Columbia, United States, ²Virginia Commonwealth University, Richmond, United States,

³Cornell University, Ithaca, United States, ⁴Merrimack College, North Andover, United States, ⁵University of Connecticut, Hartford, United States

Purpose: Most U.S. children consume excess added sugar and sodium, while two-thirds of daily calories come from ultra-processed foods (UPF), which often contain high levels of added sugars and synthetic dyes — additives linked to neurobehavioral issues. These dietary patterns elevate chronic disease risk, particularly among low-income

H. POLICIES AND ENVIRONMENTS

populations who rely on school meals for majority of their dietary intake. In response, the U.S. recently introduced the first-ever added sugar limit and strengthened sodium restrictions for school meals, with several states also implementing or considering UPF or synthetic dye restrictions. Understanding perspectives of Food Service Directors (FSDs) — who are central to policy implementation — is critical. This study explored FSDs' perceptions around implementing these new policies.

Methods: FSDs from South Carolina school districts representing the state's main regional areas were recruited. An online survey collected demographic information, followed by a 90-minute, in-person focus group. Focus group questions included perceived barriers and implications of national mandates on added sugar/sodium and the potential impact of a state-wide synthetic dye ban. Audio recordings were transcribed verbatim. Three independent coders conducted thematic analysis to identify emergent themes.

Results: FSDs (n=7; 100% female; 57% Black) had 18.6±11.9 years of experience in school nutrition. Districts used a combination of scratch cooking (85.7%) and convenience/heat-and-serve methods (100%). Four main themes emerged. *Financial strain:* FSDs expressed concerns about rising food and labor costs, coupled with stagnant reimbursement rates. They noted stricter meal standards could reduce palatability and thus participation in school meal programs, further worsening financial challenges. *Policy consistency:* FSDs emphasized the implementation of mandates should be applied uniformly at the national level. They also recommended mandates apply to all foods/beverages sold throughout the school day (e.g., competitive foods, fundraisers), not just those served by school food services. *Concerns about palatability:* FSDs worried stricter limits could negatively impact flavor and student participation in school meals. *Pride in meal quality:* FSDs expressed pride in the healthfulness of their current school meals, highlighting continuous improvements throughout recent years.

Conclusion: FSDs support equitable, nationwide standards and reimbursement rates that reflect true costs of food. Findings can inform strategies to optimize policy implementation and impact.

I-P-H.05

Navigating Physical Food Environments: Objective vs. Perceived Opportunities

S. Evers¹, A. Kemperman¹

¹Eindhoven University of Technology, Built Environment, Eindhoven, Netherlands

Purpose: Obesogenic environments, defined by easy access to energy-dense, nutrient-deficient foods, drive unhealthy dietary behaviour and rising obesity rates. Although structural interventions in the physical food environment occur gradually, digital context-sensitive strategies provide dynamic and personalised opportunities to support healthier food choices. However, their effectiveness depends on understanding and altering individuals' perceptions of their food environment. This study explored the perceived access of physical food environments by young adults and their influence on dietary habits, along with examining whether these perceptions mediate the impact of the objective environment. By integrating spatial, perceptual and behavioural data, this research aims to inform the design of personalised nutrition interventions.

Methods: In this cross-sectional study, 308 Dutch young adults (60% female; M age = 25.4 ± 3.5 years; M BMI = 24.1 ± 5.1 kg/m²) completed a self-administered Nutrition Environment Measures Survey-Perception (NEMS-P) to evaluate perceived access, availability, and accommodation of food stores and outlets, as well as realized access, quantified as visit frequency. Dietary intake was assessed using a validated Food Frequency Questionnaire (FFQ). Associations between perceived food environment characteristics and dietary intake were analysed using descriptive, correlational, and path analyses, adjusting for BMI and sociodemographic variables.

Results: Perceived availability and accommodation of the food environment significantly influenced dietary patterns, unlike perceived accessibility. Healthier food availability perceptions correlated with perceptions of store advertising and product placement as health-oriented ($\beta = 0.24$, $p < .001$). Perceiving outlets as healthier was associated with greater realized access and higher BMI ($\beta = 0.12$, $p = .03$), whereas less perceived healthfulness of outlets correlated with greater realized access to stores and increased intake of fruits and vegetables ($\beta = -0.17$, $p = .003$). Longer neighbourhood residency was associated with more favourable perceptions of the food environment, indicating that familiarity influences perceptions over time.

Conclusion: Perceptions of the physical food environment affect dietary behaviour beyond objective metrics and may not align with objective healthfulness. Digital context-aware interventions could target perceptual pathways by emphasising healthy options, recalibrating misperceptions, and employing environmental cues to promote healthier food choices. These insights aid in designing multi-level nutrition strategies, complementing longer-term structural efforts to reduce obesogenicity.

I-P-H.06

Developing a Comprehensive Tool for Measuring the Quality of Meals in Public Healthcare Facilities: Insights from the Province of Quebec, Canada

S. Harrison^{1,2}, J. Chouinard^{1,2,3}, M.-E. Labonté^{1,2,3}, L. Saulais^{1,2,4}, A.-S. Morisset^{1,2,5}

¹Observatoire de la Qualité de l'Offre Alimentaire, INAF, Université Laval, Quebec, Canada, ²Centre Nutrition, Santé et Société (NUTRISS), INAF, Université Laval, Quebec, Canada, ³Faculté des Sciences de l'Agriculture et de l'Alimentation, Université Laval, School of Nutrition, Quebec, Canada, ⁴Faculté des Sciences de l'Agriculture et de l'Alimentation, Université Laval, Department of Agri-Food Economics and Consumer Sciences, Quebec, Canada, ⁵Centre de Recherche du Centre Hospitalier Universitaire de Québec – Université Laval (CHU), Quebec, Canada

Purpose: The food offered to inpatients/residents in healthcare facilities is crucial to their health and well-being. Such institutions must uphold themselves to exemplary standards of quality and food policies. However, no comprehensive and standardized tool is available for assessing the quality of the food offered in healthcare facilities of Quebec, Canada. The purpose of this study was to develop such a tool and test its validity in public healthcare facilities.

Methods: Content was developed based on previous work and the scientific literature. Questions from existing tools were pooled and those measuring prespecified key domains were selected and adapted to the Quebec context. Then, content was submitted to a panel of stakeholders (e.g., government partners, foodservice managers) for the evaluation of face validity, using the DELPHI method. The tool was tested in healthcare facilities to compute confirmatory factor analysis and Cronbach's α . Multiple imputations were used to account for missing data.

Results: Content was developed in two parts: objective (P1, e.g., nutritional adequacy) and subjective (P2, i.e., inpatient/resident satisfaction) assessment. P2 was adapted to the facility's mission (short- or long-term care). Sixty-six questions (P1+P2) from existing tools were selected and adapted, when needed. These questions were submitted to stakeholders (n=23) in a two-round evaluation. Face-validated content consisted of two questionnaires (P1=37 questions, P2= 21 or 35 questions [short- vs. long-term care]). For further validation, participants from five diverse healthcare facilities were recruited. For P1, 5 foodservice managers completed an online questionnaire. For P2, 102 inpatients/residents completed a pen-and-paper questionnaire. Internal consistency was adequate ($\alpha=0.839$, SE=0.003). Factor loading was satisfactory ($\lambda>0.55$), except for the drinks component ($\lambda=0.376$), and correlation between latent factors ($\Phi=0.80$, $p<0.01$) suggested that constructs were related, but distinct.

Conclusion: A validated, comprehensive and context-specific tool to assess the quality of the food offered in healthcare facilities was developed in collaboration with its potential users. Next steps include a soft launch in selected facilities, followed by province-wide implementation. In the long term, this tool aims to drive continuous improvement of the food quality in healthcare facilities and serve as a key lever for public health advancement in Quebec, Canada.

I-P-H.07

Agreement of Health Canada's New Front-of-package Symbol with the Overall Nutritional Quality of Food Items Consumed in the PREDISE Study

A. Corriveau¹, M. Turcotte¹, S. Lemieux^{1,2}, M.-È. Labonté^{1,2}

¹Centre Nutrition, Santé et Société (NUTRISS), Institute of Nutrition and Functional Foods (INAF), Université Laval, Québec, Canada, ²School of Nutrition, Faculty of Agriculture and Food Sciences, Université Laval, Québec, Canada

Purpose: A previous study by our group has shown that the Nutri-Score (NS), Health Star Rating System (HSR), and Nutrient-Rich Food Index 6.3 (NRF6.3), three nutrient profiling (NP) algorithms, were associated with diet quality and health indicators in a sample from the province of Quebec, Canada. The new Health Canada's front-of-package symbol (HC-FOPS), displayed on prepackaged foods high in saturated fat, sugar and/or sodium (mandatory January 2026), was also found to be associated with diet quality and health status in the same sample (unpublished results). Since little is known yet on how these various algorithms align, this study aimed to evaluate the alignment of HC-FOPS with other validated NP models in a French-Canadian sample.

Methods: Data from the cross-sectional study *PRÉdicteurs Individuels, Sociaux et Environnementaux* (PREDISE) were used. Participants (n=1019) from Quebec completed three web-based 24-h dietary recalls (R24W). A NP score was calculated for each item in the R24W, then an energy-weighted individual score was calculated for each participant, representing the mean score of each recall. For the NS and HSR, a lower score reflects a better nutritional quality, while with the NRF6.3, a higher score reflects a better nutritional quality. The individual score for HC-FOPS was based on the energy from healthier food items (i.e., without HC-FOPS). T-tests were used for comparisons, and agreement

H. POLICIES AND ENVIRONMENTS

was assessed using weighted κ statistics and Pearson correlations.

Results: Participants consuming a higher proportion of daily energy from healthier food items (i.e., without HC-FOPS; median cut-off >75.6% of energy) had a better overall nutritional quality than participants consuming a lower proportion of energy from healthier items (NS=4.29±3.01 vs 6.58±2.85; HSR=5.27±2.06 vs 7.66±2.19; NRF6.3=16.52±7.18 vs 10.55±5.89, respectively; all $p<0.0001$). The HC-FOPS individual score showed a “fair” agreement with all three algorithms (NS weighted $\kappa=0.38$, 95% CI 0.34-0.42; HSR weighted $\kappa=0.27$, 0.23-0.31; NRF6.3 weighted $\kappa=0.32$, 0.28-0.37). The same trend was observed using Pearson correlations (NS=-0.55; HSR=-0.37; NRF6.3=0.46, all $p<0.0001$).

Conclusion: These results provide more insights regarding the alignment of the new HC-FOPS with other NP models validated in the Quebec context, therefore supporting its use to guide consumers towards healthier food choices.

I-P-H.09

Associations between the Price and the Overall Nutritional Quality of Ready-to-Eat Foods Offered in Quebec, Canada

C. Bernard^{1,2}, A. Corriveau¹, M. Turcotte¹, V. Provencher^{1,2}, M.-È. Labonté^{1,2}

¹Université Laval, Institute of Nutrition and Functional Foods (INAF), Centre Nutrition, Santé et Société (NUTRISS), Quebec, Canada, ²Université Laval, School of Nutrition, Faculty of Agriculture and Food Sciences, Quebec, Canada

Purpose: In Canada, food prices rise at an alarming rate since 2022. Foods with a better nutritional quality are often perceived as more expensive by consumers, making it difficult to support healthier choices. This project aimed to assess the associations between the price and the overall nutritional quality of ready-to-eat foods offered in Quebec, Canada.

Methods: Preliminary analyses focused on the most recent nutritional composition and retail price data collected by the Food Quality Observatory for pasta sauces (2023; $n=348$ products). Overall nutritional quality was determined using the Nutri Score (NS) 2017 algorithm, in which a lower NS score reflects a better overall nutritional quality. Associations between prices (in Canadian dollars) and NS scores were determined using ranked-based regression ($\alpha = 0.05$).

Results: Preliminary analyses indicate that, within the main category of pasta sauces, there is no association between the price of products per 100 ml and their overall nutritional quality ($\beta=-0.84$, $p=0.55$). However, in sauces specifically made of cream and/or cheese, a lower price per 100 ml is associated with a better overall nutritional quality (i.e. lower NS score) ($\beta=1.02$, $p=0.0003$). Conversely, a higher price per 100 ml is associated with a better overall nutritional quality in the subcategories of tomato-based sauces, tomato and vegetable-based sauces, and sauces without any protein source ($\beta=-10.56$, $p<0.0001$; $\beta=-3.04$, $p=0.003$; $\beta=-6.05$, $p=0.0003$, respectively). When using price per 100 kcal, a higher price is associated with a better nutritional quality in the main category of pasta sauces ($\beta=-10.19$, $p<0.0001$). Similar associations are also observed in the specific subcategories of tomato-based sauces, rosée sauces, sauces made of cream and/or cheese, sauces containing animal proteins, and sauces without any protein source ($\beta=-8.16$, $p<0.0001$; $\beta=-1.29$, $p=0.001$; $\beta=-0.89$, $p=0.03$; $\beta=-3.11$, $p<0.0001$; $\beta=-6.32$, $p=0.0002$, respectively).

Conclusion: These preliminary results suggest that the association between the overall nutritional quality and the price of pasta sauces vary depending on the price metric used, as well as on the specific subcategory of sauces analyzed. Further assessments in this category and in other categories of ready-to-eat foods are warranted to ultimately help orienting consumers toward both healthier and cheaper choices.

I-P-H.10

Assessing the Dietary and Financial Effects of Double Up Food Bucks Participation: First-time vs. Repeat Users

A. Alvarenga¹, K. Janda-Thomte², A. Falzone³, A. Nielsen¹, E. Mullane^{1,1}, T. Levy¹, H. Thornton⁴, B. Van Fossen⁴, A. van den Berg¹, S. Flores-Thorpe¹

¹UTHealth Houston School of Public Health, Health Promotion and Behavioral Sciences, Austin, United States, ²Baylor University, Department of Public Health, Waco, United States, ³UTHealth Houston School of Public Health, Epidemiology, Austin, United States, ⁴Sustainable Food Center, Austin, United States

Purpose: In the United States, more than 44 million people live in food-insecure households, lacking consistent access to enough food for an active, healthy life. While the Supplemental Nutrition Assistance Program (SNAP) provides

H. POLICIES AND ENVIRONMENTS

essential support to low-income families, many still face barriers to maintaining a nutritious diet, with food cost the most frequent challenge. The Double Up Food Bucks (DUFEB) program addresses this gap by doubling the value of SNAP benefits when used to purchase fresh fruits and vegetables (F&V). In Texas, DUFEB has expanded statewide, partnering with farmers' markets and local retailers to improve diet quality and food affordability. This presentation shares findings from the DUFEB 2025 evaluation in Texas, examining how participation length influences dietary habits by comparing first-time and repeat-users.

Methods: Intercept surveys were conducted at participating farmers' markets and grocery stores with clients who were enrolled in SNAP and used DUFEB at least one time. Surveys were completed online (self-administered) or over the phone by a trained data collector, and were available in English and Spanish. The survey included items related to DUFEB program participation duration (first time, 1-6 months, 7-12 months, over 1 year), fruit and vegetables consumption, fruit and vegetables purchases, financial stress, general health, food insecurity status and socio-demographics. Data analysis included summary statistics, Fischer Exact tests and Chi squares and regression models.

Results: The sample consisted of 213 individuals who were 79% female, 45.6% Hispanic, mean age of 38.7 years, and 85.4% food insecure. DUFEB users who were repeat users reported purchasing significantly greater amounts of vegetables ($p=0.04$) and fruit ($p=0.03$), greater variety of vegetables ($p\text{-value}=0.04$), higher levels of self-reported health ($=<.001$), and higher levels of financial stress ($p=0.04$).

Conclusion: Research has shown that the DUFEB program increases fresh F&V purchases and consumption. This study adds to the literature in that it shows that DUFEB users who were repeat-DUFEB users reported greater amounts of vegetable and fruit purchases, greater variety, and greater self-reported health status. Research to develop effective strategies to increase awareness of DUFEB (or similar financial assistance programs) and to increase DUFEB use at both farmers' markets and grocery stores is warranted.

I-P-H.11

Sugar-sweetened Beverage Intake before and after Implementation of Mexico's Front-of-Package Nutrition Warning Label Policy: Moderation by Socioeconomic Indicators among Adults in Mexico and the U.S

R.E. Davis¹, S. Alsallum², A. Jáuregui³, A. Contreras-Manzano³, C.M. White⁴, I. Garcia Perfecto³, A. Garduño-Alanis³, C. Oviedo Solis³, D. Hammond⁴, D. Fang², M. Makkar¹, J.F. Thrasher¹

¹University of South Carolina, Department of Health Promotion, Education, and Behavior, Columbia, United States,

²University of South Carolina, Department of Epidemiology and Biostatistics, Columbia, United States, ³Instituto Nacional de Salud Pública, Centro de Investigación en Nutrición y Salud, Cuernavaca, Mexico, ⁴University of Waterloo, School of Public Health Sciences, Waterloo, Canada

Purpose: In 2020, Mexico implemented mandatory front-of-package warning labels (FoPWLs) for packaged foods containing excess calories, added sugars, saturated fat, trans fat, and/or sodium. FoPWLs have been hypothesized to reduce socioeconomic inequalities in nutrition label use. This study examined trends in sugar-sweetened beverage (SSB) intake among adults in Mexico and the U.S. from the pre- (2018-2019) to post- (2020-2023) policy periods and whether changes were moderated by four socioeconomic indicators.

Methods: Data were obtained through annual, cross-sectional, online surveys conducted by the International Food Policy Study from 2018-2023 with Mexican ($n=24,574$) and U.S. ($n=25,019$) adults. Prior-week SSB consumption was queried using the Beverage Frequency Questionnaire. Weighted regression models compared pre-to-post-policy trends between countries for any SSB consumption, SSB consumption frequency, and, among consumers, SSB volume consumed. Interactions examined whether trends varied by four socioeconomic indicators: education; income adequacy; food security; or health literacy.

Results: Any SSB consumption and SSB frequency increased over time in Mexico and the U.S. ($p<0.005$), with smaller increases in Mexico ($p<0.005$). Income adequacy moderated cross-country differences in any SSB consumption over time, such that smaller increases in any SSB consumption were observed in Mexico than the U.S. among adults who found it neither easy nor difficult, difficult, or very difficult to make ends meet ($p<0.02$). When assessing SSB frequency, all socioeconomic indicators moderated differences in trends across countries. Adults had smaller increases in SSB frequency in Mexico than the U.S. if they had low or high education levels (but not medium) or if they had very low or adequate (but not low) food security (all $p<0.0001$). All differences were small in magnitude. No other evidence of moderation was observed. SSB volume increased in both countries (both $p<0.004$); however, there was no difference between countries and no evidence of moderation.

Conclusion: Implementation of the Mexican FoPWL policy was associated with smaller increases in any SSB consumption and SSB consumption frequency among adults in Mexico than the U.S. Limited evidence was found for

H. POLICIES AND ENVIRONMENTS

moderation of SSB trends by socioeconomic indicators between pre-to-post-policy implementation. The Mexican FoPWL policy appears to be mitigating – or at least not exacerbating – socioeconomic inequalities in adult SSB consumption.

I-P-H.12

Corruption and Exploitation in the Global Food System: A Focus on Forgotten Harms

T.A. Lynch¹, T.L. Penney²

¹York University, Toronto, Canada, ²York University, Global Health, Toronto, Canada

Purpose: Global food systems are failing to provide nutritious food for all and are associated with complex challenges such as poverty, non-communicable disease, and environmental degradation. Current calls for transformations around health, sustainability and equity do not yet emphasize key dynamics in global food systems including corruption or exploitation. To provide a comprehensive assessment of the forms and impacts of corruption and exploitation (C&E), this work conducts two scoping reviews to assess existing empirical literature and make recommendations to improve governance and policy.

Methods: Systematic scoping reviews were conducted following PRISMA-ScR guidelines. Key terms were searched in Scopus, PubMed, Web of Science, PsycInfo and Econlit in October 2021 and June 2025. Screeners applied selection criteria to screen articles at title-abstract and full-text levels. Data was extracted and thematically synthesized to describe C&E typologies, actors, impacts, and potential solutions. Sankey diagrams and narrative summaries were developed to summarize findings.

Results: Five types of corruption were identified in food systems: bureaucratic corruption, fraud, bribery, organized crime, and corporate lobbying. More powerful public and private actors tend to instigate corruption, while primary producers are worst-impacted. Corruption undermines food system governance and regulatory structures; threatens food security; and contributes to environmental degradation and decreased agricultural productivity.

Exploitation was found in two main modalities: abusive labour conditions and financial rent-seeking. Exploitation exists in all geographies—from OPEC to Global South states—and is inflicted by actors ranging from governments and multinational corporations to family businesses. Exploitative labour conditions are found in nearly all employment forms—whether formal or grey market, or in non-wage patrimonial systems—but financial exploitation is more common in patrimonial systems where recourse to formal banking systems is limited.

Solution-oriented literature was limited in both cases, though the essential role of strong governance, monitoring, and predictive modelling were consistently highlighted.

Conclusion: Equitable food systems are crucial pillars of human and planetary flourishing. To achieve them, policy actors must be bolstered with concrete understandings of the drivers, forms, and actors of food systems harms such as corruption and exploitation. Our analysis of the extant data marks a crucial step in this direction.

I-P-H.13

Differential Changes to Fruit & Vegetable Consumption by Neighborhood Food Environment Following Random Assignment to Enroll in a Healthy Food Voucher Program

J. Wallace¹, M. Knox², P. Chaparro^{1,3}, B. Baquero¹, J. Jones-Smith^{4,1}

¹University of Washington, Health Systems and Population Health, Seattle, United States, ²University of Washington, Economics, Seattle, United States, ³University of Washington, Food Systems, Nutrition, and Health, Seattle, United States, ⁴University of California Irvine, Health, Society & Behavior, Irvine, United States

Purpose: Fruit and Vegetable (FV) consumption is low in the United States, particularly in neighborhoods with limited access to healthy food retailers. Healthy food voucher programs (HFVPs) seek to improve FV access by providing low-income households with monthly funds to purchase FVs. Previous work demonstrates that enrollment in Fresh Bucks (Seattle, Washington), an HFVP providing \$40/month for FVs, increased FV consumption. However, it is unclear if improvements were shared equitably across neighborhood food environments. We examined whether random assignment to 6-months of Fresh Bucks enrollment versus a waitlist resulted in differential participation impacts by neighborhood food environment.

H. POLICIES AND ENVIRONMENTS

Methods: We examined 418 new Fresh Bucks applicants randomly assigned to program enrollment compared to 316 new applicants randomized to a waitlist. We additionally compared households with previous Fresh Bucks enrollment of >1 year who were randomized to either disenroll (498) or maintain enrollment (687). Participants completed a validated tool measuring FV consumption frequency in Oct 2021 (pre-enrollment) and again in Jul 2022 (post-enrollment). We leveraged random treatment assignment to identify program impacts; we estimated frequency of consuming FVs in the post-period by treatment group using a linear regression, with an interaction term between treatment group and each of four food environment variables (distance to nearest Fresh Bucks retailer; 1-mile buffer count of grocery store, convenience store, and limited-service restaurants). Models were mutually adjusted and controlled for household demographic variables.

Results: Demographic characteristics were balanced between treatment groups. Improvement in times/day consuming FVs following initial Fresh Bucks enrollment was largest among households with <2 grocery stores within 1-mile (1.23; 95% Confidence Interval (CI): 0.41, 2.04). New enrollees from households >1.5 miles from the nearest Fresh Bucks retailer demonstrated improvements in times/day consuming FVs (0.87; 95%CI: 0.20, 1.53) whereas those disenrolled reduced consumption (-0.94; 95%CI: -1.44, -0.44). For disenrolled households, access to fewer convenience stores and limited-service restaurants was associated with reduced consumption of FV.

Conclusion: FV consumption for new HFVP enrollees increased the most for those with lower access to healthy food retailers, with corresponding reductions in FV consumption for disenrolled households in similar retail environments. HFVPs may help reduce disparities associated with neighborhood food environments.

I-P-H.14

Economic Burden of Low Cardiorespiratory Fitness in France

S. Pereira¹, J. Lang^{2,3,4}, G. Tomkinson⁴, J.-P. Chaput^{5,6}, M. Touvier¹, J. Oppert^{1,7}, L. Fezeu Kamedjie¹, J. Vanhelst¹

¹Université Sorbonne Paris Nord and Université Paris Cité, INSERM, INRAE, CNAM, Center of Research in Epidemiology and Statistics (CRESS), Nutritional Epidemiology Research Team (EREN), Bobigny, France, ²Public Health Agency of Canada, Centre for Surveillance and Applied Research, Ottawa, Canada, ³University of Ottawa, School of Epidemiology and Public Health, Faculty of medicine, Ottawa, Canada, ⁴University of South Australia, Alliance for Research in Exercise, Nutrition and Activity (ARENA), Adelaide, Australia, ⁵Children's Hospital of Eastern Ontario Research Institute, Healthy Active Living and Obesity Research Group, Ottawa, Canada, ⁶University of Ottawa, Department of Pediatrics, Faculty of Medicine, Ottawa, Canada, ⁷Pitié-Salpêtrière Hospital (AP-HP), Sorbonne University, Department of Nutrition, Human Nutrition Research Center Ile-de-France (CRNH IdF), Paris, France

Purpose: The economic consequences of low cardiorespiratory fitness (CRF) have never been estimated in France. The primary objective of this study was to estimate this cost. The secondary objective was to assess the potential reduction in costs associated with a 10% decrease in the prevalence of low CRF.

Methods: A prevalence-based approach was used to quantify the direct (health care) costs of low CRF. Relative risks for developing non-communicable diseases (NCDs) and the prevalence of low CRF in France were identified through a literature review. These data were used to calculate the population attributable risk (PAR) for NCDs, with direct costs estimated using data from the French National Health Insurance system. Indirect costs (productivity losses due to premature mortality or morbidity) were assessed using a friction cost approach, assuming a friction period of 3 months. A Monte Carlo simulation was performed to account for uncertainty around the confidence intervals of the prevalence of low CRF and the RRs included in our estimates. The same methodology was applied to model the economic impact of a 10% reduction in the prevalence of low CRF.

Results: Among adults, 26.9% of men and 63.1% of women were identified as having low CRF. In 2024, direct costs of NCDs attributable to low CRF amounted to €1.993 billion for type 2 diabetes, €1.598 billion for heart failure, and €1.137 billion for dementia. The total direct costs attributable to low CRF were estimated at €11.584 billion, representing 5.6% of the annual expenditures of the French National Health Insurance in 2024. Indirect costs attributable to low CRF were estimated at €9.544 billion. A 10% absolute reduction in the prevalence of low CRF would save an estimated €3.945 billion annually (direct and indirect costs combined).

Conclusion: This study is the first to estimate the economic cost of low CRF in France. Low CRF represents a substantial economic burden in France. Given the strong association between physical activity and CRF, it is crucial to identify and implement programs and interventions aimed at improving CRF in the population, which could ultimately generate savings in healthcare and productivity costs.

I-P-H.15

Promoting Physical Activity and Reducing Overweight among Adults: Environmental Influences - A Scoping Review of Reviews

S. van der Kaaij^{1,2}, N. van der Vliet¹, K.R. O'Bright³, H. Kruize^{1,4}, L. Vaandrager²

¹National Institute for Public Health and the Environment, Bilthoven, Netherlands, ²Wageningen University and Research, Health & Society, Wageningen, Netherlands, ³Wageningen University and Research, Cultural Geography, Wageningen, Netherlands, ⁴University of Applied Sciences Utrecht, Utrecht, Netherlands

Purpose: Rising obesity rates are a growing public health challenge. Both the built and social environment can play a crucial role in promoting physical activity and reducing overweight in the long-term. Despite this recognition, there is still a lack of a recent, comprehensive overview of how the built and social environments jointly influence physical activity. This scoping review brings together the latest findings on environmental factors and interventions that promote physical activity and reduce obesity among adults.

Methods: A literature search was carried out across Scopus, PsycINFO, and Embase to find review articles published between 2018 and 2024. Reviews were included if they addressed at least one component of the built environment, with social environment factors considered when assessed alongside built features. The main outcomes examined were leisure-time physical activity, active travel, and weight status.

Results: Of the total of 1,634 review articles, 33 met the inclusion criteria. Of these, 25 focused on determinants and 8 on interventions. Built environment determinants such as walkability, street connectivity and access to destinations were consistently associated with higher levels of active travel. In contrast, leisure-time physical activity was influenced by built environment determinants such as proximity to public transit, aesthetics, and green spaces. A mix of determinants from those domains were associated with walking. The evidence on built environment factors and weight status was inconclusive. Only a few studies evaluated built environment interventions using natural experimental designs.

Conclusion: Various features of the built environment have been linked to increased leisure-time physical activity and active travel. However, current research does not provide enough evidence to establish a direct link between the built environment and weight status. Furthermore, the impact of interventions aimed at modifying the built environment is not yet well understood. Future studies should prioritise natural experiments, use both standardised and context-sensitive measures, and apply a systems approach that accounts for the interplay between different environmental factors.

I-P-H.16

Can Grocers Be Relied on to Voluntarily Improve their Online Food Labelling Practices?

L. Hebih^{1,2}, J. HY Wu^{2,3}, K. Rådholm^{1,2}, M. L. Gow^{2,3}, D. Maganja², *The last two authors contributed equally to this work and are joint senior authors.

¹Linköping University, Linköping, Sweden, ²The George Institute for Global Health, University of New South Wales, Sydney, Australia, ³The School of Population Health, University of New South Wales, Sydney, Australia

Purpose: This study assesses if major supermarkets in Australia have improved their online food labelling practices, two years after pledging to do so.

Methods: Information on individual product pages on the online stores of Australia's two largest grocery retailers was recorded using automated methods in February 2024. The proportion of pages displaying nutrition information panels (NIPs), ingredients lists, allergen declarations, country-of-origin information and Health Star Ratings (HSRs) was assessed, with prevalence compared between retailers and results from 2022.

Results: Data was collected for n=22,332 products. NIPs, ingredients lists and allergen declarations were available for around half of products (46.3-54.9%). Country-of-origin was commonly displayed (84.2%). HSRs were infrequently displayed (16.8%), and more likely displayed for high-scoring products. Compared with 2022, more products displayed NIPs (+6.1%), ingredients lists (+19.5%) and HSRs (+2.5%), while fewer showed country-of-origin information (-8.7%) and allergen declarations (-7.0%).

Conclusion: Major gaps in the provision of nutrition labels online by major Australian supermarkets continue. Labelling regulations must be updated to ensure shoppers can access important nutrition-related information online. Without it, shoppers are less able to select products that support short- and long-term health.

Exploring Dutch Municipal Advertising Restrictions on Unhealthy and Unsustainable Products

J. Stuber¹, D. Beeres², C. Dijkstra¹, S. Djojoseparto³, H. Forde⁴, M. Poelman³, F. van Lenthe², J. Mackenbach¹

¹Amsterdam UMC, Amsterdam, Netherlands, ²Erasmus MC Medical Center, Rotterdam, Netherlands, ³Wageningen University and Research, Wageningen, Netherlands, ⁴University of Oxford, Oxford, United Kingdom

Purpose: This study examined the perspectives of policy officials affiliated with Dutch municipalities exploring advertisement bans on unhealthy and unsustainable products in public outdoor spaces.

Methods: In this qualitative study, Dutch municipal policy officials were interviewed in person or online via semi-structured interviews in Autumn 2024. Interviews covered the content of proposed bans, the municipality's policy phase, key stakeholders, barriers, facilitators, and policy goals. Interviews were audio-recorded and transcribed verbatim. Analysis was based on a directed content analysis.

Results: We interviewed 18 policy officials from 13 Dutch municipalities. They indicated that advertisement bans were often initiated by left-wing council members, driven by the combination of a momentum (e.g., commitment to a healthy and green future), a favourable political climate (e.g., demand for bans from local political parties), and a policy window (e.g., revising municipality advertisement policies). They indicated that the development, implementation and long-term viability of advertisement bans depended on policy consistency (e.g., establishing definitions of products to ban), managing the risks to policy implementation (e.g., financial losses following reduced advertisement revenue) and practical barriers (e.g., existing tenders). Some policy officials doubted the impact of bans on consumer behaviours, but speculated that their signaling effect could affect public support for similar policies.

Conclusion: Political will, momentum and an opening policy window allowed for the development and sometimes implementation of advertising bans. Future research should explore wider stakeholder support for these policies, how to effectively mitigate perceived risks associated with their implementation, and their long-term impact on consumer behaviours.

I-P-H.18

Generation Zzz: Perceived Barriers and Facilitators to Delayed School Start Times in Dutch and Flemish Secondary Schools

D. Heemsker^{1,2}, A. Vandendriessche³, V. Busch², B. Deforche³, M.M. van Stralen¹, S. den Engels⁴

¹Vrije Universiteit Amsterdam, Health Sciences, Amsterdam, Netherlands, ²GGD Amsterdam, Healthy Living, Amsterdam, Netherlands, ³Universiteit Gent, Health Promotion, Ghent, Belgium, ⁴Vrije Universiteit Amsterdam, department of Health Sciences and Amsterdam Public Health research institute, Amsterdam, Netherlands

Purpose: Sleep plays a vital role in adolescents' mental, cognitive, and physical health. Yet, many adolescents today experience insufficient and poor-quality sleep. A key contributor to this problem is the misalignment between adolescents' naturally delayed circadian rhythms and the early start times of secondary schools. Although delaying school start times has been shown to improve adolescents' sleep, implementation of this policy remains limited. This study therefore aims to explore the barriers and facilitators to implementing later school start times in Dutch and Flemish secondary schools.

Methods: Semi-structured interviews (n = 18) were held with key stakeholders (i.e. school leadership or student support staff) from secondary schools in Flanders and The Netherlands that either implemented later start times or that have considered such changes. The interview guide was based on the MIDI framework. Interviews were recorded, transcribed, and thematically coded in MaxQDA 24.8.0.

Results: Stakeholders identified both barriers and facilitators across the phases of adoption, preparation, implementation, and continuation of delayed school start times. Adoption was often hindered by logistical concerns, national teaching hours requirements, ingrained routines, and perceived scheduling conflicts, though supported by awareness of adolescent sleep needs and changes in educational visions. Preparation emphasized stakeholder communication, participatory planning, and adapting schedules and regulations. Implementation challenges included concerns about later end times, but benefits such as calmer school mornings, improved student alertness, and more meaningful interactions were frequently observed. Continuation was linked to alignment with broader educational visions, teacher and student satisfaction, and perceived health and performance benefits.

Conclusion: Successfully shifting school start times requires more than overcoming logistical barriers; it depends

H. POLICIES AND ENVIRONMENTS

on strong internal leadership, alignment with pedagogical values, and a culture that allows for experimentation and adaptation. Open communication with staff and families plays a key role in building trust and support. At the same time, system-level actors, such as educational networks or government bodies, have a role to play in encouraging schools to take the first step. This includes recognizing local initiatives, providing space for peer exchange, and actively framing the measure as a credible response to adolescent health and learning needs.

I-P-H.19

Implementing Sustainability via Active Garden Education (SAGE) in Early Care and Education: Policy Alignment and Enforcement

R.E Lee¹, M. Santiago¹, M. Montserrat Ganderats-Fuentes¹, S. Marino¹, R.F Nelson¹, M. Stevenson¹, M. Breuning², C.S Hollenbeak², M. Todd¹, C.M Whisner¹, J. Szeszulski³

¹Arizona State University, Phoenix, United States, ²The Pennsylvania State University, State College, United States, ³Texas A&M Agrilife Research, Dallas, United States

Purpose: Garden-based curriculum, such as Sustainability via Active Garden Education (SAGE), in early childcare and education (ECE) facilities can increase opportunities for outdoor time, physical activity, and healthy eating. Implementation success relies on curriculum alignment with facility policies and director support. This study examined the presence and enforcement of ECE facility policies about outdoor time, physical activity, and nutrition in facilities that had previously implemented SAGE.

Methods: Directors (N=15, 93.3% women) from SAGE ECE facilities completed an online checklist derived from Nutrition and Physical Activity Self-Assessment for Child Care (NAPSACC). Surveys included items assessing demographic and facility characteristics, ECE facility policies related to outdoor time, physical activity, and nutrition, and policy enforcement (verbal, written, within the ECE facility or to outside agencies). Policy topics included circumstances around their provision, teacher modeling, staff training, and family education. Survey data were analyzed descriptively to determine how they might affect implementation strategies to improve the delivery of SAGE.

Results: Most (93.3%) directors had completed at least some college, and all had worked in ECE settings for more than five years. ECE facilities had an average of 4.7 (SD=3.1, Mode=5) classrooms and 59 (SD=41.4) students. ECE directors reported fewer policies related to outdoor play time (M=4.3, SD=1.4 of a total of 6) and physical activity (M=6.3, SD=2.6 of a total of 9) than nutrition (M=7.4, SD=3.5 of a total of 12). All but one director reported verbal and/or written enforcement of policies within the ECE facility. There was little reported enforcement outside of ECE facilities. However, this was greater with nutrition, with one third (n=5) of ECE facilities citing written reporting of policy enforcement to outside agencies.

Conclusion: ECE institutional policies supporting child behaviors consistent with SAGE's goal of improving outdoor, active time and healthy eating were mixed. Only about two thirds of potential topics were included in ECE policies. Nutrition policies had stronger enforcement, with weaker enforcement for outdoor playtime and physical activity. Implementation strategies that strengthening policy enactment and enforcement, particularly for outdoor time and physical activities, may improve sustainability and support broader adoption of garden-based, active learning curricula in ECE settings.

I-P-H.20

Agroecology as Policy Lever for Shifting Dietary Behaviour: From Production Paradigm to Behavioural Nutrition Strategy

M. Batal¹, C.I. Calderon², P. Prado³, A. Castillo⁴, R. Leon⁴, A. Deaconu⁵, D. Paredes⁶, C.A. Valle⁶, A. Gadoua⁵, A. Herath⁷, Utz K'aslemal Research Consortium

¹Université de Montréal, Nutrition, Montréal, Canada, ²University of Wisconsin Madison, Madison, United States, ³Universidad San Carlos, Guatemala City, Guatemala, ⁴TROCAIRE-Guatemala, Guatemala City, Guatemala, ⁵Canada Research Chair in Nutrition and Health Inequalities, Montreal, Canada, ⁶REDSAG, Guatemala City, Guatemala, ⁷Université de Montréal, Montreal, Canada

Purpose: Agroecology, traditionally approached as an agricultural paradigm, is an underutilized lever in behavioural nutrition change. By influencing what is produced locally, how food is symbolically valued, how identity and culture are expressed through food, and how traditional foods become socially "legitimate", agroecology does not only

H. POLICIES AND ENVIRONMENTS

change supply — it shifts behavioural environments. This includes the social normalization of seasonal diversity, the strengthening of food sovereignty as a behavioural reference frame, gender-mediated food roles, and the intergenerational transmission of knowledge. Beyond individual health benefits, agroecological transitions generate planetary co-benefits by reducing dependence on fossil-fuel-derived inputs, protecting biodiversity, maintaining soil fertility, and lowering the ecotoxic burden of pesticide-intensive food systems.

Methods: This presentation draws on the Utz K'aslemal project — a collaboration between Université de Montréal, the University of Wisconsin-Madison, TROCAIRE, the Network for Food Sovereignty in Guatemala (REDSAG), the University of San Carlos, and several local organizations mobilizing agroecology and food sovereignty with the objective of understanding and making visible the links between agroecology, food sovereignty, farmers' health and ecosystem health through a One Health lens. Among the objectives of the project, the support for advocacy is aligned with the exchange of knowledge and expertise across research, intervention, advocacy, communication activities...

In a series of workshops, we used multi-organization processes (problem-tree analysis, mapping of power, identification of SMART objectives, and the design of incidence and communication strategies) to understand farmer organizations' approaches for optimal advocacy efforts and to develop an advocacy plan aimed at decision makers at the organizational, municipal and national levels.

Results: The conversations revealed that agroecological transitions require attention to power, legitimacy, and the political economy of food. These processes highlight two blind spots for behavioural nutrition research: (1) many “determinants of choice” reside outside households — in policy architectures, in corporate control, in regulation of media narratives, and in resource allocation; and (2) without addressing these, behavioural interventions remain small in effect size because they are deployed *against* the environment, not *with* it.

Conclusion: Agroecology is a *behavioural infrastructure* — requiring political education, alliances with Indigenous authorities, strategic communication, municipal budget reforms, and targeted policy incidence — and not merely an agricultural technique.

Associations between Nine-year Exposure to Active-friendly Neighborhood Characteristics, Physical Activity and Sedentary Time: Analysis of the ORISCAV-LUX Study

J. van Beek^{1,2}, L. Malisoux³, O. Klein¹, T. Bohn³, M. Dijst^{1,2}, C. Perchoux¹

¹Luxembourg Institute of Socioeconomic Research, Urban Development and Mobility, Esch-sur-Alzette, Luxembourg,

²University of Luxembourg, Geography and Spatial Planning, Esch-sur-Alzette, Luxembourg, ³Luxembourg Institute of Health, Precision Health, Strassen, Luxembourg

Purpose: Investigate the associations between long-term exposure to active living environments and objectively measured moderate-to-vigorous PA (MVPA), light PA (LPA) and sedentary time (ST).

Methods: This study is based on a subsample of the ORISCAV-LUX cohort study in Luxembourg (n=476). Exposure to an active living environment was assessed using the Active Living Environments (ALE) index, calculated from three sub-indicators, assessing availability and proximity to 1) amenities, 2) sports facilities, and 3) recreational green and blue spaces. Exposure was defined as average exposure between the two study waves (2007-2017) and change in tertile based exposure groups (decrease/no change/increase) over the nine-year study period. Outcome measures were accelerometer derived MVPA, LPA and ST at study wave 2 (2016-2017). Generalized linear models with negative binomial distribution and logarithmic link function were applied. Included covariates were: MET-min at study wave 1 (IPAQ-SF), age, sex, educational level, marital status, lifestyle preference for being active, neighborhood socioeconomic status, season of PA measurement, urbanization level, and relocation status. Multiple imputation (n=60) was performed to deal with missing IPAQ data, as complete case analysis would have resulted in a loss of 22% of the eligible study population. Moderation analyses were performed for sex, lifestyle preference, and relocation between study waves.

Results: Preliminary results show no significant results for average ALE exposure and tertile based ALE exposure change on MVPA, LPA and ST in unadjusted models. There was a significant interaction between average exposure to ALE and relocation status, indicating higher levels of MVPA for relocated participants with higher average exposure to ALE ($\exp(\beta)=0.18$, $p=0.02$). No significant interactions were present for sex and lifestyle preference.

Conclusion: Long-term exposure to active-friendly neighborhoods showed limited direct associations with PA or ST, but relocation to more active-friendly environments was linked to higher MVPA. This result remained after accounting for lifestyles preferences, thus potentially exacerbating inequalities linked to residential self-selection processes.

H. POLICIES AND ENVIRONMENTS

I-P-H.22

Workplace Interventions to Increase Physical Activity among School Employees: A Systematic Review

K. Palmer¹, J.L. Gay², S.W. Buchholz¹, Z.D. Mulla³, E.G. Threadgill², Z. Yin⁴, J. Thapa⁵, J.J. Salinas⁶

¹Michigan State University, College of Nursing, East Lansing, United States, ²University of Georgia, Health Promotion & Behavior, Athens, United States, ³Texas Tech Health El Paso, El Paso, United States, ⁴University of Texas San Antonio, Department of Public Health, San Antonio, United States, ⁵University of Georgia, Health Policy and Management, Athens, United States, ⁶University of Texas at El Paso, Department of Social Work, El Paso, United States

Purpose: The purpose of this systematic review is to examine the effect of worksite wellness programs on physical activity (PA) behavior among primary- and secondary-school employees. Little is known about the PA levels of teachers and staff, even though nearly 8.5 million US adults are employed in schools, and existing evidence focuses almost exclusively on students' PA levels rather than on school employees' PA. Further, schools are not commonly included locations in scientific studies on worksite wellness despite their prevalence across countries.

Methods: A systematic search was conducted across PubMed, MEDLINE, Cochrane, EMBASE, CINAHL, and PsycINFO up to 2025 to examine changes in PA in response to worksite interventions promoting PA among school teachers and staff. Studies were screened by at least two people at the title and abstract as well as full-text screening stages. Changes in PA (e.g., steps, minutes) and study characteristics were documented. Risk of bias was also assessed.

Results: Seventeen studies were included in the review. Interventions had a positive (58.8%) or mixed (23.5%) impact on PA. Most studies used a one-group pre-test with post-test design: 47.1%) and 29.4% used an RCT. Follow-up duration ranged from 6 weeks to 2 years. PA outcomes were measured by self-report (47.1%), pedometers (23.5%), or both (23.5%). Intervention content focused solely on PA in 52.9% of studies, whereas the other 47.1% studies incorporated PA into broader wellness or weight-loss programs. The lack of a control or comparison group and the absence of reliability assessments of PA measures were key factors in increasing the risk of bias in quasi-experimental designs.

Conclusion: Schools are powerful social systems that can provide many resources to increase employees' physical activity. Increases in worksite programming specifically for PA or health behaviors more broadly can be applied to schools. More research is needed on potential compensation effects on leisure-time activity when adding occupational activity among school employees. Renewed interest in occupational PA in light of the 24-hour activity cycle paradigm emphasizes the need to identify effective PA promotion strategies in this unique worksite context that exists across the globe.

I-P-H.24

What Are Adults' Preferred Park Features for Encouraging Park Visitation and Physical Activity?

E. Rivera¹, B. Deforche², A. Timperio³, N. Biggs⁴, J. Veitch³

¹Central Queensland University, Appleton Institute, Melbourne, Australia, ²Ghent University, Ghent, Belgium, ³Deakin University, Institute for Physical Activity and Nutrition, Burwood, Australia, ⁴Murdoch Children's Research Institute, Melbourne, Australia

Purpose: Urban parks are important settings that can promote health across the lifespan by facilitating physical activity. Despite their availability and potential benefits, parks are not well attended by adults, and this may be due to current park designs failing to meet this age group's needs. Therefore, it is important to better understand what specific park features are most likely to entice adults to visit parks and engage in park-based physical activity. This research aimed to examine what park features are most influential on adults' choice of park to visit and be physically active and whether preferences differed by sex.

Methods: Participants (n=260, 44.8 ±12.8 years, 50% female) living in Melbourne and Sydney, Australia completed an online survey (year) with Adaptive Choice-Based Conjoint activities to identify the relative importance of various park characteristics for influencing adults' choice of park for visitation and physical activity in parks. Hierarchical Bayes (HB) estimation was performed to analyse the ACBC activities, which derived two scores: part-worth utilities and relative importances.

Results: The most valued park characteristic for both behaviours was feeling safe from undesirable people (visit:

H. POLICIES AND ENVIRONMENTS

20.7%; 95%CI: 18.7, 22.7; activity: 21.5%; 95%CI=18.9, 24.1). The second most valued characteristic for park visitation (16.0%; 95%CI=14.5, 17.4) was good upkeep and third most preferred feature was a peaceful atmosphere (14.8%; 95%CI= 13.6, 15.9). The second and third most valued features for encouraging physical activity were walking/cycling paths (15.5%; 95%CI=13.8, 17.3) and toilets (13.7%, 95%CI=11.6, 15.9). A café was the fourth most valued feature for females but eighth for males, and birdlife was the sixth most preferred feature for males, while it was tenth for females. Part-worth utilities for the features indicated that the presence of park features was favoured over their absence, and higher order feature levels (e.g., many shady trees preferred over little-to-no shady trees) were preferred.

Conclusion: These findings provide valuable insights on which features to prioritise to optimise visitation and physical activity. This is critical for park planners to inform future (re)developments, especially since changes to parks are costly and long-lasting.

I-P-H.25

Social-ecological Factors Influencing Active Travel Behavior. Systematic Review of Longitudinal Studies

S. Tittlbach¹, M. Herfet¹, A. Brockfeld¹, J. Lohmann²

¹University of Bayreuth, BaySpo - Bayreuth Center of Sport Science, Bayreuth, Germany, ²University of Augsburg, Institute of Sport Science, Augsburg, Germany

Purpose: An active lifestyle has been shown to have positive effects on health. Active travel - such as walking or cycling in daily life - can significantly contribute to both individual health and planetary well-being. Despite these benefits, there is a limited understanding of how built and sociocultural environmental factors shape active travel. This review systematically examines the impact of these factors based on a social-ecological model.

Methods: A systematic literature search following PRISMA guidelines identified longitudinal studies that investigated environmental factors on active travel among adults (<https://osf.io/6vhm4>). Ten studies with a total of 35,437 participants met the inclusion criteria: longitudinal studies and/or review articles as study design, socio-cultural and/or built environment as environmental factors, individual active travel behavior as outcome, adult men and women from Western industrialized countries with urban infrastructure, English and/or German as publication language, and publication period 2013-2024. Titles, abstracts, and full texts were screened independently by two reviewers; discrepancies were resolved by consensus. Study quality was assessed with the EPHPP tool by two independent reviewers; disagreements were resolved by consensus.

Results: On average, the 10 studies are moderate in terms of study quality. The built environment was analyzed in all 10 studies and proved to be an important factor. Enhanced infrastructure, such as cycling paths, street lighting, public transport, and workplace facilities, was associated with increased active travel behavior, depending on usage and attitudes. Socio-cultural factors, such as social norms, were analyzed in only 2 studies. Both studies indicate that socio-cultural factors may influence active travel behavior; however, this effect appears to be moderated by gender, with a stronger effect in women.

Conclusion: While the built environment clearly influences active travel, evidence regarding sociocultural factors remains sparse and inconsistent, highlighting a substantial need for further research. Integrating both dimensions appears promising, as their interaction may foster sustainable behavioral change toward active travel.

I-P-H.26

Park Availability and Physical Inactivity and Obesity in South Carolina

F. Hesam Shariati¹, A. Kaczynski¹

¹University of South Carolina, Arnold School of Public Health, Columbia, United States

Purpose: Parks can play a crucial role in promoting community health, yet their access and benefits may differ by neighborhood disadvantage. This study examined associations between park availability and physical inactivity and obesity across all census tracts in South Carolina, including variations by social vulnerability.

Methods: For all census tracts in South Carolina (n=1089), the number of available parks was extracted from Google Maps utilizing the OutScraper Application Programming Interface and expressed as a value per 10,000 residents. For each tract, we also obtained the rates of no leisure time physical activity (no LTPA) and obesity from the CDC PLACES dataset, as well as the CDC social vulnerability index and population density. No LTPA was the percentage who

H. POLICIES AND ENVIRONMENTS

reported not participating in any physical activities or exercise outside their regular jobs in the past month. Obesity was the percentage of adult respondents with a body mass index ≥ 30.0 kg/m² calculated from self-reported weight and height. Linear regression models were used to analyze the relationship between park availability and both health outcomes. We also included the moderation effect of social vulnerability and controlled for population density.

Results: For no LTPA, neither the main effect of park availability nor its interaction with social vulnerability was statistically significant. Likewise, park availability as a main effect was not significantly associated with obesity ($B=-0.029$, $p=0.057$). However, there was a significant interaction between park availability and social vulnerability in predicting obesity ($\beta=0.125$, $p=0.026$). Specifically, in tracts with low social vulnerability, greater park availability was associated with lower obesity prevalence ($\beta=-0.039$, $p=0.015$), but no significant effects were found in moderate ($B=-0.035$, $p=0.858$) or high ($B=0.032$, $p=0.311$) vulnerability tracts.

Conclusion: Park availability was generally not associated with better health outcomes across census tracts in South Carolina. While greater park access was associated with lower obesity rates in less vulnerable tracts, this benefit was not apparent in areas with higher social vulnerability. Additional data are needed about the detailed characteristics of parks to fully understand their impact on health, especially in more socially vulnerable areas where park features and quality may be lacking.

I-P-H.27

Ground Truth Validation of an Administrative Database of Exercise Facilities in Madrid: Accuracy in Identification and Classification

P. Rescia Lario¹, D.J. Mora², J.A. Santacruz³, R. Valiente⁴, L. Cereijo³

¹Universidad de Alcalá, Public Health and Epidemiology Research Group, Alcalá de Henares, Spain, ²Universidad de Alcalá, Surgery, Medical and Social Sciences, Alcalá de Henares, Spain, ³Universidad de Alcalá, Biomedical Sciences, Alcalá de Henares, Spain, ⁴Universidad de Alcalá, Geology, Geography and Environment Sciences, Alcalá de Henares, Spain

Purpose: Validate through ground truthing the administrative database of the Madrid City Council used to identify exercise facilities and collect additional data to classify them for public health research.

Methods: Exercise facilities database was obtained from the Municipal Administrative Database. A proportional stratified sampling was applied based on area socioeconomic level (tertiles) and location relative to the city center. The sample size was estimated using the finite population correction formula for proportions (95% confidence, $p=0.5$, error=5%), yielding 298 randomly selected facilities. Corresponding census tracts were visited physically by a researcher, and 10% of the sample underwent inter-rater reliability by a second researcher. During the fieldwork the following data were collected for each facility found in the field using a custom-designed smartphone App: (1) Name of the facility, (2) Address, (3) GPS Coordinates, (4) Surface area, (5) Ownership (public/private), (6) Membership type, (7) Price, (8) Type of activities offered, (9) With/without pool, (10) Opening hours, (11) Supervised/unsupervised and (12) Type of target public. These indicators were chosen based on their impact on the effectiveness of the exercise programs and the dimensions of access commented in previous works. To assess validation, we estimate the number of (1) True positives, facilities located in the database and observed in ground truthing; (2) False positives, only identified in the database; and (3) False negatives, only observed in ground truthing. After that, the sensitivity, positive predictive value, and concordance measures were calculated to determine the accuracy of the administrative database of exercise facilities.

Results: The database yielded a total of 5,135 facilities. After applying the selection criteria for cleaning, the final sample was 1,594 exercise facilities. Descriptive statistics showed a median of 1 (IQR 1-2) exercise facilities per census section. Preliminary results showed that 66% of exercise facilities within the city center are in the highest SES areas.

Conclusion: This study presents a replicable and solid methodology for ground-truthing validation. We will discuss discrepancies about secondary database accuracy by type of exercise facility and areas with different socioeconomic status.

I-P-H.28

(Co)Developing Active Mobility Policy in the Caribbean Region: Policy-oriented Physical Activity Research on the Dutch Caribbean Island of Bonaire

D. Power¹, R. Gemerts¹, P. Miel¹, M. Gentil Muñoz¹, M. Grasso¹, M. Glaser^{1,2,3}

¹Urban Cycling Institute, Amsterdam, Netherlands, ²University of Amsterdam, Faculty of Social and Behavioural Sciences, Amsterdam, Netherlands, ³Ghent University, Department of Geography, Ghent, Belgium

Purpose: Global physical inactivity remains one of societies most complex problems, especially amongst vulnerable population groups and populations in the Global South. Non-communicable disease (NCD) rates vary from region to region, and data suggest that high NCD exist amongst members of Caribbean population groups. The Dutch Caribbean municipality of Bonaire is no different, with data suggesting that 60% of Bonaire residents experience overweight, obesity, and other (oftentimes preventable) health conditions. In January 2024, Urban Cycling Institute, supported by the Ministry of Health, Welfare and Sport of the Netherlands commenced a 4-year pragmatic research project aimed at enhancing physical activity (PA) and active mobility on the island of Bonaire.

Methods: The project is a 4-year mixed methods community based action research project and is currently in its third year. The final two years of the project, 2026 & 2027, will involve a series of community based workshops/consultations with local community groups, policymakers and practitioners to develop context specific PA and active mobility policy recommendations. Workshops held in Q1 2026 and will be structured by the World Health Organisation's Walking and Cycling Policy toolkit and Global Action Plan for Physical Activity. Repeat cross-sectional observations of physical activity behaviour in 6 locations and public perception surveys are gathered annually, with supplemental qualitative data gathered by semi-structured interviews and focus groups with stakeholder and community groups.

Results: Observation and public perception data collected to date suggest that socioeconomic inequities exist amongst those who purport their interest in active mobility and those who engage in active mobility behaviour. Repeat cross-sectional observation and survey data (2024-2026) and outcomes of the workshops in Q1 2026, including the policy action development processes, will be presented at the time of the conference.

Conclusion: The research presented here aims to reduce the research to practice gap by catalysing political action and commitment to incorporate walking and cycling policy on Bonaire, in turn lowering NCD burdens and reducing congestion amongst other societal co-benefits. More generally, this research contributes novel insights into the realities of PA and active mobility policy co-development in areas of the Global South, which are typically underrepresented in PA policy research.

I-P-H.29

Increasing Accessibility of Alcohol in Digital Food Environments: Characterising the Use of Online Food Delivery Services to Purchase Alcohol and Public Health Implications

É. Demers-Potvin^{1,2}, E. Hobin^{3,4,5}, S.M. Forbes⁴, B. Smith^{4,3}, T. Poon⁴, L. Vanderlee^{2,6}

¹University of Cambridge, MRC Epidemiology Unit, Cambridge, United Kingdom, ²Université Laval, Centre NUTRISS - Nutrition, Santé et Société, Québec, Canada, ³University of Toronto, Dalla Lana School of Public Health, Toronto, Canada, ⁴Public Health Ontario, Toronto, Canada, ⁵University of Victoria, Canadian Institute for Substance Use Research, Victoria, Canada, ⁶Université Laval, École de Nutrition, Québec, Canada

Purpose: Alcohol is a leading risk factor for death and disability in Canada. Jurisdictions worldwide have eased regulations on the sale and delivery of alcohol, including through online food delivery services (OFDS) such as *Uber Eats*. As alcohol is a carcinogenic substance, increasing its accessibility through OFDS may have public health implications. This study aimed to characterise the use of OFDS to purchase alcohol among Canadian adults and to examine the association between purchasing alcohol via OFDS and hazardous alcohol use, as well as heavy episodic drinking (HED).

Methods: Data are from an online cross-sectional survey conducted among adult alcohol consumers (18-64 years) in Canada in March-April 2023 (n=5,144). Measures assessed frequency of alcohol purchasing through OFDS, hazardous alcohol use (measured by the Alcohol Use Disorder Identification Test-Concise (AUDIT-C)) and HED ($\geq 4/5$ drinks for women/men on one occasion at least monthly in the past 12 months). A logistic regression model examined differences in the use of OFDS to purchase alcohol across sociodemographics. Two separate adjusted models explored the association between OFDS alcohol purchasing and 1) hazardous alcohol use; 2) heavy episodic drinking.

H. POLICIES AND ENVIRONMENTS

Results: Purchasing alcohol through OFDS in the past year was associated with hazardous alcohol use (AOR=3.99,95%CI:3.32-4.79 [AUDIT-C score $\geq 3/4$]) and HED (AOR=3.90,95%CI:3.29-4.61). Overall, 16% of respondents had purchased alcohol from an OFDS at least once in the past year. The use of OFDS to purchase alcohol at least once in the past year was more likely among respondents identifying as men (AOR=1.75,95%CI:1.48-2.06) than women, among those with low perceived income (AOR= 1.89,95%CI:1.60-2.23) than those with high perceived income, among those with a child living at home (AOR=1.48,95%CI:1.24-1.77) compared to none and among racially minoritized groups (AOR=2.05,95%CI:1.73-2.43) compared to those identifying as White. Generation Z and Millennials were more likely to have used OFDS to purchase alcohol in the past year than all other generations (AOR>2.03 for all).

Conclusion: Using OFDS to purchase alcohol in Canada is relatively uncommon, but adults who do so are more likely to report hazardous and heavy episodic alcohol use. Findings suggest that restricting the accessibility of alcohol in digital food environments could improve public health.

I-P-H.30

Environmental and Psychosocial Contexts of Device-measured Physical Activity and Sedentary Behaviour in Semi-urban Nepal: A Multilevel Analysis

R. Shrestha^{1,2}, S. Paudel³, T.B. Adhikari¹, R.Ø. Nielsen¹, A. Vaidya⁴, D. Neupane^{5,2}, P. Kallestrup¹

¹Aarhus University, Department of Public Health, Aarhus C, Denmark, ²Nepal Development Society, Department of Public Health, Kathmandu, Nepal, ³University of Melbourne, Centre for Adolescent Health, Department of Paediatrics Melbourne Medical School, Melbourne, Australia, ⁴Kathmandu Medical College, Community Medicine, Kathmandu, Nepal, ⁵Johns Hopkins University, Department of International Health, Bloomberg School of Public Health, Maryland, United States

Purpose: This study examines the relationship between environmental opportunities and psychosocial contexts, and device-measured physical activity and sedentary behaviour among adults in semi-urban Nepal.

Methods: We conducted a cross-sectional analysis using baseline data (March–August 2024) from the Community-Based Promotion of Physical Activity (COBIN-PA) trial in Pokhara Metropolitan City, Nepal. Physical activity and sedentary behaviour were assessed using wrist-worn accelerometers worn continuously for seven days. Environmental characteristics reflecting recreational or built opportunities (e.g. parks and walking paths) and productive or utilitarian opportunities (e.g. agriculture, domestic work, and walking for daily tasks), as well as psychosocial factors (perceived behavioural control and intention), were assessed using structured questionnaires. Multilevel linear mixed-effects models with random intercepts for clusters were employed to estimate the associations between daily moderate-to-vigorous physical activity (MVPA) and sedentary time. Interaction terms assessed whether perceived behavioural control modified environmental associations.

Results: We analysed data from 421 participants. Higher productive or utilitarian environmental opportunity scores were linked to about 10 additional minutes of daily MVPA per standard deviation increase. In contrast, scores for recreational or built environments showed weak or inconsistent associations with MVPA. Perceived behavioural control showed a positive association with MVPA, with each unit increase corresponding to roughly 30 additional minutes of MVPA per day. In contrast, intention was not associated with MVPA. There was no statistically significant interaction between the recreational environment and perceived behavioural control. Environmental and psychosocial factors showed largely no associations with sedentary time.

Conclusion: In semi-urban Nepal, utilitarian environmental opportunities and perceived behavioural control were more strongly and consistently associated with device-measured physical activity than psychosocial intention alone. Sedentary behaviour showed weaker, distinct associations. These results suggest the need for context-sensitive, multi-level strategies that prioritise everyday movement opportunities alongside individual-level interventions to promote active living in low- and middle-income countries.

I-P-H.31

Spatial Distribution of Syndemic Hazards in the Built, Food and Climate Environment across Deprivation Levels: Cross-city Comparison in Four African Cities

T. Canelas¹, F. A. Wayas², Y. Wasnyo³, D. Odekunle⁴, M. Godongwana⁵, F. Assah³, L.K. Micklesfield⁶, E.V. Lambert⁷, A.S. Lopes⁸, W.T. Caiaffa⁹, M. Thondoo¹, T. Oni¹, L. Foley¹

H. POLICIES AND ENVIRONMENTS

¹University of Cambridge, Epidemiology Unit, Cambridge, United Kingdom, ²University of Cape Town, Cape Town, South Africa, ³University of Yaounde I, Yaounde, Cameroon, ⁴University of Lagos, Lagos, Nigeria, ⁵South African Medical Research Council, Cape Town, South Africa, ⁶University of the Witwatersrand, SAMRC/Wits Developmental Pathways for Health Research Unit, Johannesburg, South Africa, ⁷University of Cape Town, Research Centre for Health through Physical Activity, Lifestyle & Sport (HPALS), Cape Town, South Africa, ⁸University of Planalto Catarinense, Postgraduate Program in Environment & Health, Santa Catarina, Brazil, ⁹Federal University of Minas Gerais, Observatory for Urban Health in Belo Horizonte, Belo Horizonte, Brazil

Purpose: African cities are experiencing a rapidly increasing burden of non-communicable diseases (NCDs), driven by the co-occurrence of adverse built, food, and climatic environments. While deprivation is often assumed to align with greater exposure to these risks, little is known about how multiple NCD-relevant hazards cluster spatially within cities or whether deprivation gradients operate consistently across different urban contexts.

Methods: We conducted a cross-sectional, small-area analysis across four African cities: Cape Town and Soweto (South Africa), Lagos (Nigeria), and Yaoundé (Cameroon). Built and food environment hazards were assessed using in-person audits based on MAPS-Global and EPOCH instruments, while climatic hazards included surface urban heat island intensity, extreme rainfall frequency, and air pollution (PM_{2.5}/PM₁₀). Hazard domains were aggregated at the small-area level, z-standardised within each city, and combined to derive a syndemic hazard score. Small areas were classified by relative deprivation, and deprivation contrasts were calculated to characterise socioeconomic patterning.

Results: Syndemic hazard gradients varied markedly across cities. Cape Town and Soweto exhibited clear socioeconomic stratification, with higher syndemic hazards concentrated in high-deprivation areas. In contrast, Lagos showed a reversed gradient, driven by more adverse built and food environments in low-deprivation areas alongside higher climatic hazards in deprived areas. Yaoundé displayed weak and mixed deprivation patterns, with substantial overlap between groups. Domain-specific analyses revealed that climatic hazards followed expected deprivation gradients in all cities, while built and food environment hazards showed context-specific and divergent patterns that shaped the composite syndemic profiles.

Conclusion: The spatial clustering of syndemic hazards in African cities is highly context-specific and not uniformly aligned with deprivation. These findings challenge one-size-fits-all assumptions about deprivation vulnerability and highlight the need for urban health and climate policies that reflect city-specific configurations of risk. Integrated, multi-sectoral approaches addressing built, food, and climatic environments are essential for effective NCD prevention in rapidly urbanising African contexts.

I-P-H.33

Revitalizing the US Youth Presidential Fitness Test: Is State Policy Infrastructure Ready to Support Schools?

C. Killian¹, E. D'Agostino², B. Kern³, C. Kim⁴, D. King⁵, S. Albeke³, H. Thompson⁶

¹University of New Hampshire, Kinesiology, Durham, United States, ²Duke University School of Medicine, Orthopaedic Surgery, Durham, United States, ³University of Wyoming, Kinesiology and Health, Laramie, United States, ⁴Duke University School of Medicine, Biostatistics and Bioinformatics, Durham, United States, ⁵University of Wyoming, Geographic Information Science Center, Laramie, United States, ⁶University of California Berkeley, Community Health Sciences, Berkeley, United States

Purpose: Fitness testing provides reliable and valid information on present and future child health outcomes. However, for a nation-wide fitness testing program to be successful, it must be implemented within a well-supported and executed physical education (PE) infrastructure backed by policies supporting adequate PE instructional time, a trained PE teacher workforce, fitness testing data collection and reporting, and accountability and enforcement mechanisms. This study examined current state-level elementary school fitness testing policy infrastructure to assess readiness for wide-scale fitness testing outlined under the reestablished US Presidential Fitness Test.

Methods: We conducted a cross-sectional policy analysis including all 50 US states drawing data from the State of the States Policy Report. Cross-sectional state-level policy analysis examined: (1) Physical education instructional time, teacher qualification, standards; (2) fitness testing requirements, assessment instruments, reporting mandates; and (3) PE-specific policy oversight, enforcement. Scores were standardized (0-1 range) and averaged to create a composite fitness testing policy readiness index.

Results: The mean US composite state-level fitness testing policy readiness score for elementary schools is 0.57 (range: 0.36-0.75). All states explicitly identify health-related fitness within PE standards or curriculum framework, and nearly all (n=48 [96%]) require PE licensed instructors. Only five states (10%) mandate the recommended 150-minutes per week of elementary PE time and most (n=37 [74%]) require <60 weekly minutes. Twenty-four states (48%) have

H. POLICIES AND ENVIRONMENTS

no requirements for fitness testing, while 11 (22%) recommend fitness testing and only three require it annually. Only six states (12%) mandate submission of fitness testing results to state agencies and only four (8%) require results be made publicly accessible. Most states ($n=34$ [68%]) assign local control to monitor PE and fitness testing compliance. Only 16 states (32%) require state oversight, but most ($n=11$ [22%]) lack enforcement consequences.

Conclusion: Although school-based PE fitness testing provides reliable and valid information on child health and clinical outcomes, US state-level policy infrastructures are not yet positioned to support standardized, large-scale fitness testing. For the Presidential Fitness Test to provide a meaningful lever for US youth public health promotion and surveillance, systematic policy reform and resulting school-level PE infrastructure changes are necessary.

I-P-H.34

Digital Chameleons of the Food Environment: An Exploratory Analysis of the Shapeshifting Nature of Dark Kitchens in Australia and their Regulatory Challenges

S. Jia^{1,2}, H. Brown³, H.J. Moore^{4,5}, A.A. Gibson^{6,2}, A. Lake^{5,7}, S. Partridge^{1,2}

¹The University of Sydney, Sydney School of Nursing, Sydney, Australia, ²The University of Sydney, Charles Perkins Centre, Sydney, Australia, ³Lancaster University, Division of Health Research, Lancaster, United Kingdom, ⁴Teesside University, School of Social Sciences, Humanities and Law, Middlesbrough, United Kingdom, ⁵Fuse - The Centre for Translational Research in Public Health, Newcastle, United Kingdom, ⁶The Leeder Centre for Healthy Policy and Economics, School of Public Health, Sydney, Australia, ⁷Teesside University, Centre for Public Health, Middlesbrough, United Kingdom

Purpose: Dark kitchens are food service models that do not have a physical space for patrons and mostly sell through online food delivery services. Due to their low overhead costs and lack of customer facing premises, dark kitchens are transient systems with ability to open and close quickly and this is potentially facilitated by use of generative artificial intelligence (AI) for branding. This study aimed to characterise dark kitchens in Australia, assessing longevity of businesses, the nutritional quality of menu items; as well as identify and characterise use of AI in generation of menu content.

Methods: From an existing 2023 dataset of 16,158 food outlets on UberEats operating in New South Wales, Australia, dark kitchens were classified as outlets that had multiple brand names operating from one unique address. Additional information was web-scraped including the opening status of the outlet, menu item names, descriptions, price and images. If dark kitchens had appeared closed on UberEats, we searched their brand names on DoorDash, to obtain additional data. Data on dark kitchens were summarised by descriptive analyses key outcomes included 1) percentages of cuisines; 2) proportion of dark kitchens open by day and hour; and 3) frequency of menu items classified into food group categories. Menu item images were analysed assessing distinct features that appeared artificial or altered.

Results: In 2025, over a third of dark kitchen brands ($n = 98$, 33.1%) had temporarily or permanently closed since the initial dataset was web-scraped in 2023. We subsequently identified 197 unique dark kitchen brands still in operation. Over 70% of total menu items were comprised of unhealthy foods including fries, fried chicken and desserts. Additionally, nearly 60% ($n = 1939/3376$) of menu item images contained “enhanced image” or “image touchup” in their URLs, indicating enhancement or alteration of food images.

Conclusion: Dark kitchens are emerging as “kitchen chameleons” – with the ability to quickly change menu offerings and branding while primarily selling junk foods. Use of AI solutions to generate food images may also impact on consumer purchasing decisions. Adaptive monitoring is needed to inform and develop policy to minimise their potential risks to public health.

I-P-H.35

Two Decades of Food Consumption and Adherence to Dietary Guidelines among Belgian Adults: Evidence from Three National Surveys (2004–2023)

S. Bel¹, I. Moyersoen¹, M.S. Vasquez¹, N. Berger¹

¹Sciensano, Epidemiology and Public Health, Brussels, Belgium

Purpose: This study examined long-term trends in habitual food consumption and adherence to nationally defined food-based dietary guidelines (FBDG) among Belgian adults between 2004 and 2023, including sex and age differences. Innovation lies in the harmonised assessment of food-group-level intake across three nationally representative

H. POLICIES AND ENVIRONMENTS

surveys using a single updated national FBDG framework, allowing consistent evaluation of changes in adherence over nearly two decades.

Methods: Data were obtained from three Belgian National Food Consumption Surveys conducted in 2004, 2014–15, and 2022–23, including representative samples of adults aged ≥ 18 years ($n=2,493$; $n=1,226$; $n=1,499$). Dietary intake was assessed using two non-consecutive 24-hour recalls (GloboDiet) complemented by a food propensity questionnaire. Habitual intake distributions were modelled using the SPADE two-part approach, accounting for consumption probability, amounts consumed, and never-consumers. Reported values represent modelled mean habitual intakes. Foods were classified according to the 2025 Belgian FBDG and adherence assessed using guideline-specific cut-offs. Analyses were stratified by sex and age group (18–39, 40–64, ≥ 65 years) and weighted for age, sex, socioeconomic status, and season.

Results: Between 2004 and 2022–23, vegetable intake increased from 131 to 172 g/day, and adherence to the ≥ 300 g/day recommendation rose from 1% to 7%. Water consumption increased from 647 to 985 ml/day, with the proportion consuming ≥ 1 L/day rising from 19% to 43%. Unprocessed red meat intake declined from 413 to 322 g/week, increasing adherence to the <300 g/week recommendation from 37% to 54%. Alcoholic beverage consumption declined from 210 to 126 g/day, while never-consumers increased from 10% to 17%. In contrast, adherence remained low or declined for wholegrain products (7% meeting ≥ 125 g/day in 2022–23), fruit (8% meeting ≥ 250 g/day), milk and milk products (11% meeting ≥ 250 g/day), and fish and shellfish (20% meeting ≥ 200 g/week). Younger adults showed poorer adherence across food groups.

Conclusion: Despite partial improvements, overall adherence to FBDG among Belgian adults remains low, with continuing age-related inequalities. Coordinated, targeted public health strategies are needed to improve dietary behaviours and reduce diet-related disease burden across the population.

I-P-H.36

Who Buys Local? Demographic Predictors and Perceived Barriers to Local Food Purchasing in a Regional Area of Australia

K. Charlton¹, A. Digssie Gebremariam², K. Kent²

¹University of Newcastle, School of Health Sciences, Newcastle, Australia, ²University of Wollongong, School of Medical, Indigenous and Health Sciences, Wollongong, Australia

Purpose: Local food systems are increasingly promoted for their potential to improve diet quality, strengthen community resilience, and support environmental sustainability. However, evidence remains limited regarding who participates in these systems and what factors influence engagement. This study addresses this gap through a mixed methods approach examining how consumers and retailers in the Illawarra Shoalhaven region of New South Wales perceive, access, and participate in local food systems.

Methods: An online cross-sectional survey of 666 adults assessed attitudes toward local food, perceptions of the local food environment, and experiences of food insecurity. Local food consumers were defined as those purchasing local foods from three or more sources. In-depth interviews were conducted with 14 local food retailers from the same region to explore sustainability practices, sourcing decisions, and constraints within local supply chains. Transcripts were analysed using inductive thematic analysis following Braun and Clarke's (2006) guidelines.

Results: Strong support for local food was evident, with more than half of both local ($n = 191$) and non-local ($n = 322$) consumer groups rating local food as "important" or "very important." Affordability, limited farmers' markets, and few community gardens emerged as common barriers, and demographic characteristics did not differentiate local from non-local consumers. Although most respondents perceived healthy food as available and accessible, fewer than 40% considered it affordable. Retailer perspectives aligned with consumer views, citing cost pressures, inconsistent supply, and supermarket competition as major challenges to sourcing and promoting local products. Retailers described varied interpretations of sustainability, spanning regenerative agriculture, reduced packaging, financial viability, and waste minimisation. While consumers valued freshness, quality, and community support, purchasing behaviours were shaped by price sensitivity and convenience.

Conclusion: This study demonstrates shared values between consumers and retailers regarding the benefits of local food but highlights substantial economic and logistical barriers limiting wider participation. Strengthening regional food systems will require coordinated policy actions that support small producers, improve affordability, expand retail infrastructure, and promote local food options within an environment dominated by supermarket influence. Findings highlight a gap between community aspirations for sustainable, localised food systems and the structural constraints shaping purchasing and sourcing behaviours.

H. POLICIES AND ENVIRONMENTS

I-P-H.37

Do Perceptions of Neighbourhood Walkability Modify Associations between Objective Walkability and Accelerometer-measured Physical Activity?

L. Frehlich¹, S.A. Prince², J.J. Lang², G.R. McCormack¹

¹University of Calgary, Calgary, Canada, ²Public Health Agency of Canada, Ottawa, Canada

Purpose: Perceived and objective measures of neighbourhood walkability have been associated with physical activity (PA); however, these measures are only marginally correlated and do not always agree. Perceived walkability may be influenced by objective features of the built environment. Our study examined whether perceived neighbourhood walkability modifies the associations between objective walkability and accelerometer-measured PA, and whether this modification is consistent by sex and age groups (young: 18-40 years; middle-aged: 41-64 years).

Methods: We used nationally representative data from the Canadian Health Measures Survey, including 1,167 females and 1,233 males with accelerometer-measured daily minutes of moderate-to-vigorous PA (MVPA) and total daily steps. Perceived walkability was measured using a modified Physical Activity Neighbourhood Environment Scale (PANES), and objective walkability was derived from the Canadian Active Living Environments (Can-ALE) national dataset. Using generalized linear models, we estimated covariate-adjusted associations including a multiplicative interaction term between objective and perceived walkability to assess effect modification. Analyses were conducted in pooled samples and stratified by sex and age group.

Results: Objective walkability was associated with steps for young females ($\beta=150$; 95%CI: 15-284) and MVPA for middle-aged females only ($\beta=1.49$; 95%CI: 0.36-2.63). A significant objective-by-perceived interaction was only observed in males for both MVPA ($\beta=0.71$; 95%CI: 0.15-1.27) and steps ($\beta=120$; 95%CI: 38-203). Results stratified by age identified effect modification for only middle-aged males for both MVPA ($\beta=1.05$; 95%CI: 0.40-1.71) and steps ($\beta=133$; 95%CI: 26-241). Among middle-aged males, higher perceived walkability buffered against a negative association between increasing objective walkability and both daily MVPA and steps.

Conclusion: Perceived walkability modified associations between objective walkability and accelerometer-measured MVPA and steps among middle-aged males, but not among females or younger males. Suggesting that, for some groups, favourable perceptions may be important for objective walkability to promote PA. In contrast, objective walkability alone was positively associated with steps and MVPA among women. Overall, findings indicate that perceived and objective walkability should be considered in both PA promotion efforts and future research on built environment-PA relationships.

I-P-H.38

Independent and Joint Associations of Objective and Perceived Neighbourhood Walkability with Transportation and Recreational Physical Activity in Canada

L. Frehlich¹, S.A. Prince², J.J. Lang², G.R. McCormack¹

¹University of Calgary, Calgary, Canada, ²Public Health Agency of Canada, Ottawa, Canada

Purpose: Walkable neighbourhoods provide opportunities for physical activity (PA) through transportation (TPA) and recreation (RPA). Objectively measured and perceived neighbourhood walkability are independently associated with PA, yet there is limited evidence concerning their joint effects on TPA and RPA. Our study examined the independent and joint effects of objective and perceived walkability on weekly minutes of TPA and RPA in males and females, separately.

Methods: Using data from the Canadian Health Measures Survey (CHMS; n=3,995 adults; 48% female), including self-reported weekly minutes of TPA and RPA, perceived neighbourhood walkability, and sociodemographic characteristics. CHMS data were linked to objective walkability (Canadian Active Living Environments Index; Can-ALE) via participants' residential postal codes. We fit covariate-adjusted hurdle models for TPA and RPA (participation, and duration among participants), and derived unconditional population-average marginal effects. Models were estimated for pooled and sex-stratified samples. Models included objective and perceived walkability simultaneously, and then added an objective-by-perceived interaction term to determine whether perceived walkability modified associations of objective walkability with TPA and RPA.

Results: Among females, 46% participated in TPA (average=180 min/week) and 50% in RPA (average=188 min/week); among males, 41% participated in TPA (average=183 min/week) and 50% in RPA (average=240 min/week). Objective

H. POLICIES AND ENVIRONMENTS

walkability was positively associated with TPA (pooled $\beta=9.39$; 95%CI: 0.61-11.18; males $\beta=7.75$; 95%CI: 5.42-10.08; females $\beta=11.60$; 95%CI: 8.88-14.31). Perceived walkability was also positively associated with TPA in the pooled and male-only samples (pooled $\beta=5.53$; 95%CI: 1.55-9.50; male $\beta=6.00$; 95%CI: 0.31-11.68). Among males, perceived walkability was positively associated with RPA ($\beta=8.13$; 95%CI: 0.61-15.66). Interaction effects for perceived and objective walkability suggest a synergistic association for TPA but an antagonistic association for RPA among males. No interactions were observed for females.

Conclusion: Objective walkability was positively associated with TPA in both sexes. Perceived walkability showed additional associations in males and interacted with objective walkability, with patterns differing for TPA versus RPA. Promoting PA may benefit from combining built environment changes with strategies to promote neighbourhood perceptions.

I-P-H.39

Do Perceptions Reflect Reality? Associations between Objective Food Environments and Perceived Healthy Food Availability in Australia

A.D. Gebremariam¹, K. Charlton², E. Neale¹, D. Venstin³, K. Kent¹

¹University of Wollongong, School of Medical, Indigenous and Health Sciences, Wollongong, Australia, ²University of Newcastle, School of Health Sciences, Newcastle, Australia, ³University of Tasmania, School of Health Sciences, Launceston, Australia

Purpose: Perceptions of local food environments influence dietary behaviours. Yet, little is known about how closely these perceptions reflect objectively mapped food environments in regional Australia. This study examined the association between spatially derived indicators of healthy food outlet availability and community perceptions in the Illawarra-Shoalhaven region of New South Wales.

Methods: Objective food environment measures were constructed from a regional mapping dataset by identifying and classifying food outlets and calculating suburb-level indicators of healthy and unhealthy outlet availability, including supermarket presence, unhealthy-to-healthy/less healthy outlet ratios, Relative Healthy Food Availability (RHFA), and Relative Fast-Food Availability (RFFA), with continuous metrics categorised into tertiles. Perceptions of the food environment were obtained from 666 participants in a cross-sectional survey. Perceived availability of healthy food outlets was assessed using five Likert-scale items (1 = strongly agree to 5 = strongly disagree) covering access to healthy food stores, restaurants/café, community gardens, farmers' markets, and fast-food outlets (reverse coded). Items were averaged to create a composite score (higher score = poorer perceived availability). Associations were examined using multivariable linear regression.

Results: Over half of respondents (54.1%) disagreed or strongly disagreed that their neighbourhood had enough healthy food outlets; only 4.2% felt positively about availability. After adjustment for covariates, supermarket presence was associated with better perceived healthy food availability (adjusted $\beta = -0.27$; 95% CI: -0.41 to -0.14). Higher ratios of unhealthy to healthy/less healthy outlets were associated with poorer perceptions (high: $\beta = 0.27$; 95% CI: 0.1-0.44; medium: $\beta = 0.20$; 95% CI: 0.04-0.35). High RFFA was associated with poorer perceptions ($\beta = 0.20$; 95% CI: 0.02, 0.38). In contrast, both high and medium RHFA were associated with better perceived availability (high: $\beta = -0.24$; 95% CI: -0.43, -0.05; medium: $\beta = -0.26$; 95% CI: -0.41, -0.10)

Conclusion: This study demonstrates that perceived availability of healthy food outlets aligns with objectively measured food environments, highlighting the role of local retail structure in shaping experiences of food access in regional Australia. Strategies that increase healthy outlet availability and reduce fast-food concentration may help address regional inequities in food access.

I-P-H.40

Evaluating Municipal-level Food Environment Policies in Zabrze, Poland: Expert Assessment and Community-derived Policy Options. An Insight into FOODPATH Project Results

P. Romaniuk¹, K. Kaczmarek¹, K. Alcer¹, N. Zadworna-Strzeszyna¹, K. Brukało¹

¹Medical University of Silesia, Department of Health Policy, Bytom, Poland

H. POLICIES AND ENVIRONMENTS

Purpose: This study aimed to assess municipal policies shaping the local food environment in Zabrze, Poland, and to co-create and prioritise actions to improve access to healthy diet, with a focus on structural rather than individual-level interventions.

Methods: Using an adapted Food Environment Policy Index (Food-EPI) we organized 2 workshop sessions for food policy experts and wider community representatives. The experts evaluated the current level of implementation of 54 good-practice indicators grouped in 11 domains including local food production, food promotion, provisioning, retail, food waste, social food support, leadership, governance, financing, monitoring and “Health in All Policies”. Each indicator was scored on a Likert scale reflecting implementation level and impact on socio-economic inequalities. Based on these results, representatives of local communities proposed 14 municipal actions (e.g. strengthening local producers, improving public food provisioning, water access, redistribution, NGO integration and governance). Experts then rated each action for importance, feasibility and equity on 1–14 scales; mean and median scores and rank-based classifications were calculated for each dimension.

Results: Food environment policies in Zabrze were generally assessed as weak to moderate compared to international good practice, with particularly low implementation in retail regulation, food marketing, comprehensive monitoring and dedicated food-governance structures, and relatively stronger performance in public food provisioning, access to free drinking water, and coordinated social food support. Among the 14 actions, those scoring highest across importance, feasibility and equity included: sustainable public food provisioning (increasing the share of local, health-promoting food and short supply chains in municipal institutions), systematic partnerships with NGOs within the food security system, structured municipal coordination of food initiatives, and comprehensive monitoring of local food environments and food waste. Actions targeting education and communication, seniors’ support, and financial mechanisms also scored positively but ranked lower on feasibility or equity.

Conclusion: A structured Food-EPI assessment combined with community co-creation and expert prioritisation yielded a focused, equity-sensitive municipal food policy agenda for Zabrze. Prioritised actions emphasise governance, sustainable public procurement, NGO partnerships and monitoring, illustrating how mid-sized Polish cities can translate food environment diagnostics into a concrete portfolio of policy interventions to advance healthier and more equitable diets.

I-P-H.41

A Scoping Review on the Influence of Food Industry Practices on Equitable Access to Healthy Food Environments

E.W. van Duin¹, M. Steele², J. Harrington², F. De Block¹, A. Van Puyvelde¹, G. Cardon¹, S. Vandevijvere³

¹Ghent University, Ghent, Belgium, ²University College Cork, Cork, Ireland, ³Sciensano, Brussels, Belgium

Purpose: Individuals in socio-economically vulnerable circumstances are disproportionately exposed to unhealthy food and beverages due to their greater accessibility, availability, and visibility. Since the Lancet series on the *Commercial Determinants of Health* (CDoH), research has increasingly explored the corporate influences on public health and inequities. This heightened attention prompted a comprehensive scoping review, as part of the Era4Health FoodPath project, to summarize the literature examining how company practices shape equitable access to healthy food environments.

Methods: Four databases - Scopus, MEDLINE, Web of Science, and Embase - were systematically searched for peer-reviewed English-language studies. *ASReview* and *Rayyan* software were used for screening. Eligible studies addressed intersections between the food environment, equity, and the CDoH. The review covered studies published between 2000, following the introduction of the *Angelo framework*, and 2024. The *INFORMAS Food-EPI* framework helped structure food environment policy domains, while studies on tobacco and alcohol industries were excluded. The results were analysed according to mechanisms of inequity and food environment characteristics.

Results: A total of 320 studies met the inclusion criteria. The majority (80%) of the studies were conducted in the USA, Canada, Brazil, Australia, and the UK. The types of popular food outlets and their healthiness differed per country or location. Of the 320 studies, 79% concluded that company practices (partially) disadvantaged socio-economically vulnerable groups. Among studies reporting (partial) inequality-increasing effects, 35% of the studies attributed this to unhealthy outlet exposure and 20% to unhealthy options. This was mostly studied from the perspective of what is sold inside or around a certain location or neighbourhood (88%) and without zooming in on a specific commodity (80%). Only 18% of the studies focussed on children or adolescents, in which there was a general consensus that there was a social gradient related to the exposure to fast food and fast food marketing.

Conclusion: For a more comprehensive understanding of the food environment and the cultural or geographical differences, a diversification of studied countries, as well as food domains is necessary. This review emphasizes that

H. POLICIES AND ENVIRONMENTS

company practices have been widely connected to inequalities. It underscored that CDoH must be considered in policy development.

Physical Activity Policy, Research, and Evaluation Network (PAPREN) Rural Hub: Collaboration across Research and Practice

J. Stroope¹, M.E. Wende², C. Beattie³, L.E. Balis⁴, C. Abildso⁵, C.K. Perry⁶, M.R. Umstattd Meyer⁷

¹Louisiana State University, School of Kinesiology, Baton Rouge, United States, ²University of Florida, College of Health & Human Performance, Gainesville, United States, ³Texas A&M AgriLife, Institute for Advancing Health Through Agriculture, College Station, United States, ⁴Center for Nutrition & Health Impact, Omaha, United States, ⁵West Virginia University Extension, Morgantown, United States, ⁶Oregon Health & Science University, Portland, United States, ⁷Baylor University, Robbins College of Health and Human Sciences, Waco, United States

Purpose: Rural U.S. communities face well-documented challenges in implementing and sustaining physical activity promotion efforts, including geographic dispersion, travel distance, and fewer environmental supports. The Physical Activity Policy, Research, and Evaluation Network (originally PAPRN: 2004-2014, PAPRN+: 2014-2019, PAPREN: 2019-present) is a national collaboration funded by the Centers for Disease Control and Prevention (CDC) that advances physical activity through policy and environmental approaches. The Rural Hub (formerly called the Rural Active Living Workgroup) meets monthly to share research, practice experiences, funding opportunities, and policy developments. Member-guided subgroups meet between sessions to produce tools, briefs, data resources, and scientific products (e.g., manuscripts, presentations). The purpose of this abstract is to share a scalable model for ongoing research–practice collaboration.

Methods: Research and practice impacts were collected through multiple data sources, including tracking spreadsheets updated during meetings, meeting minutes, responses to update request emails, Google Scholar searches, and brief participant surveys. Data sources were collated and descriptive statistics were used to examine impacts by process (e.g., number of subgroups) and outcomes (e.g., publication, practice-focused presentations).

Results: The overall workgroup/hub and interest-focused subgroups have partnered across all CDC-funding cycles to address rural needs and evidence gaps, disseminating findings through international and national conferences, practice-focused presentations, and scientific publications. Ten interest-focused subgroups have been formed since 2023 around topics including rural physical activity patterns, youth sports, food security and active transportation, extreme weather and physical activity, and community- and policy-level physical activity promotion. Full details about the number of papers, presentations, and outlets for these products, and how this collaboration has been supported across the years will be presented in this poster.

Conclusion: The history of the Rural Active Living Workgroup / Rural Hub illustrates a scalable model for sustained research–practice collaboration focused on rural physical activity environments. Ongoing engagement helps generate innovative ideas, identify research gaps, and support cross-sector translation. Investing in structured practitioner–researcher networks can accelerate rural research-to-practice translation and better align evidence with implementation.

I-P-H.43

Customer, Owner, and Staff Perspectives on Nutrition Labeling in Hispanic Restaurants: A Qualitative Study

M. Chouliara¹, C. Gubor¹, P.-J. Chen², A. Flores Lecea², Z. Wu², H. Lee¹

¹Texas A&M University, Nutrition, College Station, United States, ²Texas A&M University, Arch H. Aplin III '80 Department of Hospitality, Hotel Management and Tourism, College Station, United States

Purpose: Menu labeling policies help consumers make informed food choices. However, limited research is focused on independently owned establishments that make up a substantial portion of the Hispanic food landscape in the United States. These small businesses often lack the financial resources needed to implement menu-labeling practices. This study conducted a qualitative interview among customers, owners, and staff in independently owned Mexican restaurants in East-Central Texas. By examining multiple stakeholder perspectives, the study aimed to provide context-specific insights to inform the future development of bilingual, digital menu labeling strategies.

H. POLICIES AND ENVIRONMENTS

Methods: Thirty-four participants aged 19-79 years participated in semi-structured interviews conducted in English or Spanish. The interview guide was informed by Theory of Planned Behavior and Social Cognitive Theory. Data analysis followed a deductive and inductive thematic approach, in which theoretical constructs served as sensitizing concepts. Data was analyzed using Dedoose software.

Results: Thematic analysis of customer interviews identified five major categories: (1) Contextual Meaning of Healthy Eating, (2) Engagement with Nutrition Information, (3) Desired Types and Formats of Information, (4) Reactions to Digital Menus, and (5) Language Preferences. Customers described Mexican restaurant dining as an indulgence. While most customers did not seek out calories or nutrient values, younger adults and individuals with fitness goals expressed some interest. Participants preferred simple and optional formats. Views on digital menus were mixed, with many preferring paper menus. Digital formats were recommended for translation or supplemental information. Bilingual materials were widely endorsed. The themes that emerged from staff and owners included: (1) Perceived Customer Interest, (2) Concerns About Customer Reactions, (3) Staff Knowledge and Confidence, (4) Operational Challenges, (5) Format Preferences, and (6) Language Accessibility. Staff and owners perceived low customer demand, worried that calorie information might deter diners, reported low confidence in answering nutrition questions, and described challenges in generating accurate information.

Conclusion: Customers' preferences for unobtrusive nutrition information, combined with staff concerns about feasibility and customer reactions, indicate that menu-labeling strategies must balance transparency with the preservation of the desired dining atmosphere. Future studies should examine how culturally tailored labeling interventions affect ordering behavior and customer satisfaction in independent ethnic restaurants.

I-P-H.44

Operationalising the Food Environment as an Environmental Value: A Transdisciplinary Case Study in Amsterdam

S. Dijkstra¹, M. ter Bogt¹, A. de Ruijter², M. Poelman³, J. Lakerveld⁴, A. Wagtendonk⁴, B. Wallage², W. Waterlander¹

¹Amsterdam UMC Location Vrije Universiteit, Public and Occupational Health, Amsterdam, Netherlands, ²University of Amsterdam, Law for Health and Life, Faculty of Law, Amsterdam, Netherlands, ³Wageningen University & Research, Social Sciences, Chair Group Consumption & Healthy Lifestyles, Wageningen, Netherlands, ⁴Amsterdam UMC Location Vrije Universiteit, Epidemiology and Data Science, Amsterdam, Netherlands

Purpose: Unhealthy food environments are a major driver of overweight, obesity, and diet-related non-communicable diseases. While fiscal, marketing, and labeling policies on (un)healthy food have received increasing attention, the potential of urban planning law to regulate food outlet distribution based on health criteria remains underexplored. Many municipalities currently lack clear instruments to restrict unhealthy food outlets on health grounds, including the Netherlands. This study examined in a real-world case in the Netherlands the legal, empirical, and operational foundations needed to develop a regulatory instrument to support healthier community food environments.

Methods: We conducted a transdisciplinary case study in Amsterdam (2020–2026) involving legal scholars, public health and nutrition scientists, and municipal policymakers. The study was structured around three research questions. First, a doctrinal analysis assessed the legal conditions under which the food environment could be integrated as a planning criterion within Dutch urban planning law. Second, we investigated whether these conditions were met by conducting a rapid literature review and a quantitative validation study of a neighborhood food environment score. Third, we translated the legal and empirical insights into a concept regulatory instrument and decision-making framework for municipal use.

Results: Preliminary results are provided. The legal analysis suggests that Dutch urban planning and municipal law, particularly the new Dutch Environmental and Planning Law, provides a potential blueprint for municipalities to create a framework for regulating food outlet distribution, if health impacts can be translated to spatially relevant measurements. The literature review suggests that in legal terms there is evidence that unhealthy food environments cause serious public health harm, justifying preventive action under the precautionary principle. Primary results of the validation study suggest that the food environment can be operationalised as an environmental value through a neighborhood food environment score.

Conclusion: This study suggests the scope conditions for how legal and empirical evidence can be integrated into an urban planning framework to make it possible to regulatory instrument to support municipalities in creating healthier food environments. Future research should evaluate its feasibility, acceptability, and effectiveness in pilots and real-world municipal practice.

Healthy Active Learning Improves inschool Physical Activity and Strengthens Healthy Food Environments in Aotearoa New Zealand Primary Schools

A. Ali¹, J. Carpendale², K. Nanavati³, K. Mumme¹, J. Godfrey⁴, O. Mugridge³, D. Pillay¹, C. Wham¹, B. Erueti⁵, W. Wood¹, J. Jackson⁶, S. Molchanov⁷, J. Adams³

¹Massey University, School of Sport, Exercise and Nutrition, Auckland, New Zealand, ²Massey University, Institute of Education, Auckland, New Zealand, ³Eastern Institute of Technology, Auckland, New Zealand, ⁴Massey University, School of Mathematical and Computational Sciences, Palmerston North, New Zealand, ⁵Massey University, School of Health Sciences, Palmerston North, New Zealand, ⁶Manukau Institute of Technology, Auckland, New Zealand, ⁷Massey University, School of Economics and Finance, Auckland, New Zealand

Purpose: We evaluated Healthy Active Learning, a 5-year joint government initiative (Sport NZ, Health NZ, Ministry of Education) to improve children's wellbeing through healthy eating, drinking, and quality PA in ~900 schools throughout NZ.

Methods: A mixedmethods, timeseries evaluation (baseline data collection 1 (DC1): 2020–21; mid-term (DC2): 2022–23; post-intervention (DC3): 2024–25) combined quantitative and qualitative data from ~55 primary schools (students aged 5–13 years) throughout NZ. Data collection included student surveys (PA, motivation, engagement), teacher/leader and parent surveys, food policy/practice audits, and wristworn accelerometry (ActiGraph xGT3x). DC3 sample sizes were for: student PA n=4,868, motivation n=4,162, engagement n=3,836; teacher n=1,086; school leader n=319; parent n=2,279; food policy/practice n=140 schools; and accelerometry n=502. Analyses used regression tree and linear mixed models with stratification by age, gender, ethnicity, urbanicity, and school equity index.

Results: Inschool activity increased at DC3 ($p<0.05$): +4% steps/h, -4% sedentary time, +2% MVPA min/h; outofschool (-5% steps, +3% sedentary, -13% MVPA and weekend (-8% steps, +3% sedentary, -17% MVPA) activity declined. Active transport remained <50% in urban areas; during breaks, 75.2% of boys and 66% of girls were active. Access to quality and inclusive PA opportunities improved (leaders reporting opportunities that meet needs: 73%→85%; teachers: 67%→83%), with rural advantages in facilities/access; enjoyment of PE remained high (94%), but motivation indicators showed a decline in feeling encouraged (77%→68%) and gender gaps persisted (girls less likely than boys to feel good at/included in PE). Schools with a written healthy food policy increased (72%→84%); “water and plain milk only” policies were widely embedded and policy development was led primarily by school leadership (91%). Student involvement in promoting healthy food environments rose (39%→52%).

Conclusion: Healthy Active Learning has strengthened healthy food environments and increased inschool PA while outofschool and weekend PA declined; sustaining gains will require continued crossagency support to extend opportunities beyond the school day and to address persistent gender and equity gaps.

I-P-H.46

Evaluating the Impact of a Culturally Tailored Produce Prescription Program among Pregnant Individuals in Low-income and Low-access Communities

B. Martinez¹, M. Mueller¹

¹Colorado State University, Food Science and Human Nutrition, Fort Collins, CO, United States

Purpose: This study tests whether a culturally tailored Produce Prescription Program (PPR) during pregnancy increases fruit and vegetable intake and improves maternal-infant outcomes. We hypothesize that participation will increase intake from baseline to follow-up and that greater dietary improvements will be associated with lower risk of gestational diabetes, pre-eclampsia, and preterm birth, and healthier birth weights. This study is innovative in linking a healthcare-based food access intervention to both dietary behavior change and clinical outcomes during pregnancy, an understudied focus in PPR research.

Methods: We will conduct a community-engaged, longitudinal pre/post evaluation of a culturally tailored PPR among pregnant participants (anticipated N = 200) receiving care at a Federally Qualified Health Center. Fruit and vegetable intake will be assessed at baseline and follow-up using a validated dietary screener. Clinical outcomes, including preterm birth and infant birthweight, will be abstracted from clinical records, along with patient-reported diagnoses (e.g., gestational diabetes mellitus, pre-eclampsia). Mixed effects linear regression will estimate within-person changes in intake over time. Multivariable logistic regression will examine associations between dietary change and binary outcomes, and linear regression will assess associations with continuous outcomes. Models will adjust for

H. POLICIES AND ENVIRONMENTS

maternal age, parity, pre-pregnancy BMI, race/ethnicity, and socioeconomic indicators. Adjusted effect estimates (β coefficients and odds ratios) with 95% confidence intervals will be reported. Sensitivity analyses will examine robustness to missing data and variation in program exposure.

Results: Preliminary data from 76 pregnant patients indicate substantial need: 29% reported household food insecurity, 7% met daily fruit recommendations, and 5% met daily vegetable recommendations at baseline. Data collection for the full cohort is ongoing. Based on prior PPR evaluations using comparable screeners, we anticipate mean increases of approximately 0.8–1.0 times/day in combined fruit and vegetable intake from baseline to follow-up. Power calculations indicate >80% power to detect moderate within-person dietary changes and clinically meaningful differences in birth outcomes ($\alpha=0.05$).

Conclusion: Findings will provide evidence on how healthcare-based food access interventions support dietary behavior change during pregnancy and inform strategies to address nutrition-related maternal health disparities in racially/ethnically diverse, low-income populations.

I-P-H.47

Evaluation of the Effects of a Multi-strategic Intervention for Promoting Bicycle Mobility and Health in the Context of City Development in Duesseldorf: A Natural Experiment

L. Stähler¹, S. Weyers¹, O. Kuß^{2,3}, A. Lang², B. Hoffmann⁴, V. Soppa⁴, L. Oberwinster⁴, S. Nehr⁵, T. Pohl⁵, C.R. Pischke¹

¹Institute of Medical Sociology, Centre for Health and Society (chs), Medical Faculty and University Hospital Düsseldorf, Heinrich Heine University Düsseldorf, Düsseldorf, Germany, ²Institute for Biometrics and Epidemiology, German Diabetes Center, Leibniz Center for Diabetes Research at Heinrich Heine University Düsseldorf, Düsseldorf, Germany, ³Centre for Health and Society (chs), Medical Faculty and University Hospital Düsseldorf, Heinrich Heine University Düsseldorf, Düsseldorf, Germany, ⁴Institute of Occupational, Social and Environmental Medicine, Centre for Health and Society (chs), Medical Faculty and University Hospital Düsseldorf, Heinrich Heine University Düsseldorf, Düsseldorf, Germany, ⁵Faculty of Mechanical and Process Engineering, University of Applied Sciences Düsseldorf, Düsseldorf, Germany

Purpose: As part of its “Mobility plan D,” the City of Duesseldorf is implementing multiple measures to promote a modal shift from car use towards active mobility. This natural experiment investigates the effects of this multistrategic intervention (i.e., continuous expansion of traffic-calmed cycling routes, mobility sharing stations, media activities) on cycling behavior and related health outcomes. The study aims to: (a) evaluate the impact of the multistrategic bicycle infrastructure intervention on infrastructure use; (b) identify determinants of cycling behavior across different sociospatial contexts; (c) assess exposure to trafficrelated air pollutants on trafficcalmed versus conventional cycling routes; and (d) examine health effects of cycling on trafficcalmed versus conventional routes.

Methods: To address aims (a) and (b), cycling volumes are measured with two automatic bicycle counters along the intervention route crossing two districts with different levels of sociospatial deprivation, and with 16 control counter stations distributed across the city of Duesseldorf. The initial baseline measurement took place in the entire month of June in 2025, 12-, and 24-months follow-ups are foreseen in 2026 and 2027. Determinants of cycling behavior are assessed using an online survey at baseline (starting in June 2026) and 12month followup in both intervention districts. Focus groups and interviews are conducted in the more socioeconomically disadvantaged district. To address aims (c) and (d), concentrations of trafficrelated air pollutants are measured via mobile monitoring on trafficcalmed versus conventional cycling routes. Additionally, health outcomes (e.g., blood pressure, arterial stiffness, pulmonary function) are assessed before and after cycling among participants riding along both route types. The first measurement wave took place in 2025 with data collected from 43 participants.

Results: This submission presents the study design. Data collection and analysis are ongoing and results are therefore not yet available.

Conclusion: This study provides insights into cycling infrastructure use and determinants of cycling in Duesseldorf, and generates evidence on the relevance of trafficcalmed cycling routes for health outcomes in different urban populations.

H. POLICIES AND ENVIRONMENTS

I-P-H.48

Young People's Use of Convenience Stores: What Influences Purchasing Behaviours and How can Policy be Developed to Support Health in This Setting?

A. Bird^{1,2,3}, M. Mason^{2,4}, N. Green^{1,2}, C. Vogel^{3,5}, K. Woods-Townsend^{2,6}, J. Bird^{2,3,7}, S. Muir^{3,5}

¹University of Southampton, Faculty of Medicine, Human Development and Health, Southampton, United Kingdom, ²NIHR Southampton Biomedical Research Centre, University of Southampton and University Hospital Southampton NHS Foundation Trust, Southampton, United Kingdom, ³MRC Lifecourse Epidemiology Centre, University of Southampton, Southampton, United Kingdom, ⁴University of Southampton, School of Healthcare Enterprise and Innovation, Faculty of Medicine, , Southampton SO16 6YD, Southampton, United Kingdom, ⁵University of London City St Georges, Centre for Food Policy, London, United Kingdom, ⁶School of Healthcare Enterprise and Innovation, University of Southampton, Faculty of Medicine, Southampton, United Kingdom, ⁷NIHR Applied Research Collaboration Wessex, Southampton Science Park, Innovation Centre, Southampton, United Kingdom

Purpose: One third of young people (YP) in the UK are considered overweight or obese before they start secondary school. Adolescence is an important life stage when people begin making independent food choices. Convenience stores, which are conveniently located near schools, are an environment where YP begin to make these decisions. Small businesses such as independent convenience stores are excluded from the policy that bans the prominent placement of high-fat, high-salt, and high-sugar foods and drinks, a core staple of convenience store sales. This study aimed to understand how young people use independent convenience stores and their purchasing behaviours within them.

Methods: A multiphase qualitative design was used, comprising of nine focus groups (n=43 YP aged 11-16) and a mystery shopper task (n=8 YP aged 16-18). Focus group participants were purposively sampled from two secondary schools, one rural and one urban in Hampshire, England. Mystery shoppers visited convenience stores identified near participating schools with the task of purchasing a "healthy snack". Mystery shoppers then completed a survey reflecting on their experiences. Data from both phases were analysed using inductive thematic analysis. YP worked with researchers to finalise themes and co-create an infographic.

Results: YP visited the convenience stores on their school commute and used stores as "third spaces" for socialising with friends. Purchases centred on low-cost "treats" and energy drinks: healthy options were rarely chosen as convenience stores were visited specifically to buy treats and age-restricted items. Students commented that there were fewer healthier food items and these were "hidden" in the stores compared to less healthy items, which were at the front of the store. Students suggested that clear, healthy displays, prominent positioning, fresher, more appealing products, providing healthier alternatives to treats, and competitive pricing could all support healthier purchases.

Conclusion: Current placement strategies and product availability in independent convenience store environments do not nudge YP to healthy food and drink choices. This study supports the ongoing evaluation of Government legislation and the need for public health initiatives to assist independent convenience stores and those that supply them to make changes to support their local community.

II-P-H.01

Comprehensive Planning for Whom?: An Intersectional Analysis of Stakeholder Perspectives

Y. Mui¹, C. Antonacci¹, L. Weidemann¹, K. Pollack Porter¹, J. Wolfson¹, J. Jones-Smith²

¹Johns Hopkins Bloomberg School of Public Health, Baltimore, United States, ²University of California, Irvine, Irvine, United States

Purpose: Urban planning, a structural determinant of health, shapes the conditions influencing access to essential resources. Comprehensive plans—policy frameworks guiding priorities in land use, transportation, housing, economic development, and increasingly, food access—serve as critical levers that determine who benefits from these systems. Advancing equity, therefore, requires examining how planning processes define problems, prioritize actions, and reflect community interests. This study explores how planning stakeholders conceptualize inequities, prioritize policies, and navigate the drivers and barriers to advancing equity in comprehensive plans.

Methods: This study, part of the Structural Opportunities to Rebuild Equitable Environments (StOREE) Study, examined how structural racism and historical planning decisions shape current food environments and obesity disparities in six U.S. jurisdictions: Baltimore, MD; Chicago, IL; Forsyth, NC; Los Angeles, CA; Minneapolis, MN; and New

H. POLICIES AND ENVIRONMENTS

York City, NY. We conducted a thematic analysis of 41 semi-structured interviews with planners, community members, and other stakeholders involved in comprehensive plan development, using inductive and deductive codes, guided by the Intersectionality-Based Policy Analysis Framework.

Results: Planners conceptualized equity as a mostly spatial phenomenon, recognizing overlapping disparities in health and social determinants. In contrast, community partners and other stakeholders viewed inequities as complex problems requiring holistic solutions. Some planners acknowledged impacts of past inequitable policies (e.g., redlining) on present-day issues (e.g., housing affordability) yet often described being constrained in advancing equity goals by a dependency on market-based development, lack of political will, and the absence of actionable policy or implementation mechanisms. While housing and transportation inequities were prioritized in plans as direct land use issues, food-related goals and proposed actions received less attention and connections to land use were more limited (e.g., urban agriculture). However, when planners engaged intentionally with historically excluded communities using democratized consensus-building strategies, issues like limited food access emerged as a central planning concern and catalyst for explicit equity commitments.

Conclusion: Findings indicate the need to move beyond spatial framings of equity and more fully integrate food-related inequities into comprehensive plans. Embedding implementation plans can help translate equity goals into action, while centering community leadership in the planning process can provide a pathway to address issues most meaningful to affected communities.

II-P-H.02

Sustainable Transport in Glasgow City Region: A Photo-elicitation Study of the Facilitators and Barriers to Sustainable and Active Travel

M. Bissett¹, E.R Lawlor¹

¹University of Glasgow, School of Cardiovascular and Metabolic Health, Glasgow, United Kingdom

Purpose: The Clyde Metro project aims to connect Glasgow City Region's communities through a fully integrated public transport system over the next 30 years. To promote sustainability and improve health, integrating public transport with active travel (cycling, wheeling, walking) is key. However, to address transport, health, and social inequalities, more needs to be known about how communities experience travel, especially those facing access barriers. This research aims to explore and identify ways to support adults who may face access barriers to using sustainable and active travel in the Glasgow City Region.

Methods: Photo-elicitation and traditional interviews (in person and online) were conducted with adults who face barriers to public transport (e.g. older adults, those with a health conditions or illnesses, parents of young children etc.). Eligible participants were asked to complete a screening questionnaire and purposively sampled to recruit across a range of barriers, geographic areas and transport modes. Participants were provided with the option to receive a digital camera to take photos of their daily travel which were then used as prompts in the interview. Interviews were audio-recorded, transcribed and analysed thematically.

Results: Participants (N=22) were recruited from across five council areas and many participants faced intersecting barriers to sustainable transport use, including chronic health issues, frailty and the cost of travel. Walking was the most common mode to access transport, but poor pavement conditions and insufficient lighting were key barriers. Barriers to cycling included poor cycling infrastructure (e.g. inappropriate bike lane designs, lack of bike parking) and limited access to bike-sharing stations. Participants supported better integration of walking and cycling with public transport, including safe routes and signage to stops and stations.

Conclusion: This project offers insights into integrating active and sustainable travel to promote physical activity and enhance connectivity across Glasgow City Region. By sharing the findings with key stakeholders, this study has the potential to inform the development of sustainable transport solutions that could make a lasting impact on the health and wellbeing of residents across Glasgow.

II-P-H.03

Trends in the Community Eligibility Provision Participation Over a Decade: An Analysis of Eligible Schools in the United States

T. Dykstra¹, R.R. Azghan¹, J. Cohen², P. Ohri-Vachaspati¹

¹Arizona State University, Phoenix, United States, ²Merrimack College, North Andover, United States

H. POLICIES AND ENVIRONMENTS

Purpose: School meal programs in the United States are typically funded using a three-tiered structure (free, reduced-price, and paid) based on student's household income. Implemented in 2014, the Community Eligibility Provision (CEP) is a federal reimbursement program offering low-income schools the ability to serve free meals to all enrolled students without the need for individual student applications. CEP participation has been associated with increased access to and participation in school meals which are often the healthiest meals students consume each day. However, not all eligible schools participate in CEP. Policy changes in recent years have expanded schools' eligibility to enroll in CEP. This study aimed to examine the trends in school CEP participation from 2014 through 2024 and identify differences in adoption rates across school characteristics.

Methods: This descriptive study used national school data from the National Center for Education Statistics for school-level characteristics and the Food Research and Action Center database for CEP eligibility and participation data. A fuzzy matching algorithm and large-language-model-based approach were used to match the two datasets. The percentage of schools participating in CEP was examined by urbanicity, school type, and school-level.

Results: Based on descriptive analysis, we found an overall increase in participation among eligible schools from 42.4% in 2014 to 84.3% in 2024. Urban areas had higher overall participation at both time points (53.9% in 2014 to 89.6% in 2024), compared to rural areas (39.2% in 2014 to 79.6% in 2024). In 2014, compared to public schools, a greater proportion of charter schools participated in CEP (40.2% vs 51.5%), but these differences disappeared by 2024 when a similar proportion (about 84%) of charter and public schools participated in CEP. Participation in CEP increased across all school levels (elementary, middle, and high) to a similar extent over time. Mixed model analyses will be conducted to determine differences in school CEP participation based on school characteristics controlling for other covariates.

Conclusion: Understanding trends of CEP adoption over time has important implications for school nutrition programs in the United States to identify potential strategies to increase school meal participation and access to healthy school meals for students.

II-P-H.04

Mapping and Understanding Physical Activity Policies in Poland and Lithuania: Lessons from National Evidence Documents Development Process

J. Zukowska¹, R. Jankauskienė², W. Kustra¹, M. Baceviciene², C. Woods³

¹Gdańsk University of Technology, Gdańsk, Poland, ²Klaipeda University, Klaipeda, Lithuania, ³Limerick University, Limerick, Ireland

Purpose: The primary purpose of this study is to describe and compare the processes of developing and validating national evidence documents in Poland and Lithuania as part of the implementation of the Physical Activity Environment Policy Index (PA-EPI). The research addresses the following key questions: How feasible is the validation process in different governance contexts, and what factors facilitate or hinder effective engagement of policy makers across sectors? By examining two contrasting administrative systems, the study aims to generate insights into intersectoral collaboration and the applicability of the PA-EPI in Central and Eastern Europe.

Methods: This qualitative comparative study adopts a case study approach focusing on the development and validation of national evidence documents in both countries. Data were generated through document analysis and structured feedback from policy makers collected via validation questionnaires and written comments. The data were analyzed thematically to identify key patterns related to stakeholder engagement, intersectoral collaboration, and governance context. The analysis enabled a cross-country comparison of enablers and barriers in the PA-EPI validation process, highlighting both shared challenges and country-specific approaches to implementing physical activity (PA) policies.

Results: In both countries, efforts were made to attract a diverse and representative group of policy makers. In Lithuania, ministries and municipalities (central and local level) were officially invited to delegate representatives. In Poland, policy makers were invited mainly through professional networks resulting in a smaller but highly engaged group providing qualitative feedback. Main remarks concerned the clarity of evidence, intersectoral coordination, and the need to link national actions to measurable PA outcomes. Although benchmarking against international best practice is still ongoing, the findings highlight strong stakeholder commitment and confirm the feasibility of the validation process in both governance contexts.

Conclusion: The study demonstrates that the PA-EPI provides a feasible and structured framework for engaging policy makers in evaluating national physical activity policies. Both Poland and Lithuania successfully built cross-sector coalitions that enhanced the credibility and comprehensiveness of the validation process. Comparative insights from these two contexts offer valuable lessons for other Central and Eastern European countries aiming to strengthen evidence-informed and equity-oriented approaches to physical activity policy development.

H. POLICIES AND ENVIRONMENTS

Associations between Length of Residence, Sense of Community, and Health Behaviors in a Master-planned Community: Insights from Harris County, Texas

MR. Umstattd Meyer¹, E.C. Lewis², A. MacMillan Uribe², D. L. Villarreal², M.S. Patterson³, J. Vigil¹, K.M. Janda-Thomte¹, G. Han⁴, C. Hall⁵, J.E. Maddock⁶

¹Baylor University, Robbins College of Health and Human Sciences, Department of Public Health, Waco, United States,

²Texas A&M University System, Texas A&M AgriLife Research Institute for Advancing Health Through Agriculture, Dallas, United States, ³Texas A&M University System, School of Public Health, Department of Health Behavior, College Station, United States, ⁴Texas A&M University System, School of Public Health, Department of Epidemiology and Biostatistics, College Station, United States, ⁵Texas A&M University System, Department of Horticultural Sciences, College Station, United States, ⁶Texas A&M University System, School of Public Health, Department of Environmental and Occupational Health, College Station, United States

Purpose: Master-planned communities (MPCs) are intentionally designed developments that integrate housing, retail, and recreational spaces, creating opportunities for targeted health-promotion. However, most research on MPCs has focused on comparisons with conventional neighborhoods, offering limited insight into how length and quality of residence within these communities may influence health behaviors. This study describes demographic and behavioral characteristics of adults residing in a large MPC in the United States and examines associations between length of residence, sense of community, and health behaviors.

Methods: Adults residing in an MPC in Harris County, Texas completed online surveys between May-October 2025. Validated self-report scales were included: Brief Sense of Community Scale, International Physical Activity Questionnaire (IPAQ-SF), Mediterranean Eating Pattern for Americans (MEPA-16), People and Nature Survey, and Perceived Stress Scale. Sociodemographic characteristics and self-rated health were also reported. We ran two multivariate general linear models to examine associations for (1) length of residence and (2) sense of community with physical activity (log-transformed), diet, nature contact, and stress, adjusting for sociodemographic covariates.

Results: Respondents (n=128; mean age=39.2±10.1 years; 61.9% female) were racially and ethnically diverse and highly educated. Average length of residence was 2.8±2.1 years. Most reported moderate levels of sense of community (M=29.4±6.7), perceived stress (57% moderate), and diet quality (MEPA-16=8.6±2.0). Median moderate-to-vigorous physical activity (MVPA) was 1,550 MET-min/week (IQR=2,055). In the first model, longer length of residence was significantly associated with greater perceived stress (p=.039) but not physical activity, diet, or nature contact. Among covariates, older age was associated with lower stress (p=.013), whereas having more children was associated with higher stress (p=.037). In the second model, greater sense of community was significantly associated with lower perceived stress (p=.010), but not physical activity, diet, or nature contact. Among covariates, age was negatively associated with physical activity (p=.037), and number of children was positively associated with perceived stress (p=.007).

Conclusion: Findings suggest that community connectedness may play a more influential role in shaping wellbeing than length of residence in this context. Future longitudinal research is needed to clarify these relationships and guide the design of scalable MPC models that sustain health promotion over time.

II-P-H.06

From Policy to Practice: Quantitative Evaluation of a School Meal Reform

A. Fink^{1,2}, H. Kilb^{1,2}, A. Brindle^{1,2}, O. Reis^{1,2}, M. Kölsch^{1,2}, A.L. Seidler^{1,2}

¹University Medical Center Rostock, Clinic for Child and Adolescent Psychiatry, Rostock, Germany, ²German Center for Child and Adolescent Health (DZKJ) Site Greifswald/Rostock, Clinic for Child and Adolescent Psychiatry, Rostock, Germany

Purpose: Childhood overweight and obesity are major risk factors for both physical and mental health conditions. Studies have shown an increased risk of diet-related diseases such as diabetes, as well as mental health disorders including depression and anxiety. Excess weight acquired during childhood often persists into adulthood. Children from families with low socioeconomic status are particularly affected. Systematic reviews indicate that parent-focused behavioral interventions have limited effectiveness when environmental conditions do not support healthy choices. In contrast, setting-based approaches are considered more promising.

H. POLICIES AND ENVIRONMENTS

With the beginning of the 2025/26 school year, the City of Rostock (Germany) implemented a shift in lunch catering across all public schools to a municipal provider (“Mittagsmatrosen”) with the aim of providing regional, healthy, and sustainable meals. This intervention will be scientifically evaluated to assess its impact on dietary behavior, weight development, and health equity.

Methods: We conduct quantitative surveys among students, parents, and teachers to assess eating habits, participation in school meals, and subjective evaluations. In addition, anthropometric data (height, weight) are collected, and meal plans and portion sizes are analyzed. Comparative analyses before and after the introduction of the “Mittagsmatrosen” will be used—where feasible—to identify changes in acceptance, participation rates, and health-related parameters.

Results: Preliminary findings presented at the conference will focus on participation in school meals following the shift to regional and healthy options, the differential effects on children from various socioeconomic backgrounds, and the nutritional composition of meals. The study will also provide projections regarding the intervention’s impact on dietary behavior and weight development.

Conclusion: The evaluation of the “Mittagsmatrosen” initiative offers an opportunity to establish Rostock as a model region for health-promoting school nutrition. The project is expected not only to contribute to the prevention of overweight and obesity but also to enhance physical and mental health as well as academic performance. Evidence-based policy recommendations for other municipalities can be derived. The results will be critical for ensuring the sustainability of the initiative and for reducing health inequalities among children and adolescents.

II-P-H.07

Evaluating Israel’s Front-of-package Labelling Policy: A National Nutritional Profile of the Retail Food Environment

A. Venger¹, O. Avishai-Ofer¹, L.S. Taillie², A. Troen¹, E. Ert¹

¹The Hebrew University of Jerusalem, Rehovot, Israel, ²University of North Carolina - Chapel Hill, Chapel Hill, United States

Purpose: Front-of-package labelling (FOPL) is a core nutrition-policy tool to improve population diets by steering consumers toward healthier products and motivating industry reformulation. Israel’s 2020 dual-label system—mandatory red nutrient warnings and voluntary green endorsement labels—is unique internationally but has not been systematically assessed at the market level. This study evaluated the nutritional profile, labelling prevalence, and price patterns of foods sold in Israel’s retail environment two years after policy implementation.

Methods: A cross-sectional analysis was conducted on 7,884 products from two major supermarket chains representing ≈ 45 % of national grocery sales. Product data were scraped from online catalogues (Nov 2022), classified into 15 food groups, and coded for FOPL status, nutrient composition, and price. Nutrient and price densities were analyzed using Kruskal–Wallis/Wilcoxon tests with Dunn’s post-hoc corrections. Analyses compared labelled vs unlabelled items, warning-type combinations, and food-group differences.

Results: Overall, 45 % of products carried at least one red warning label (sugar 24 %, saturated fat 23.8 %, sodium 16.5 %), as compared to 52% unlabelled products; only 3.4 % displayed voluntary green labels despite 12.2 % eligibility. Snack foods dominated the market (26.6 %) and were heavily labelled (70 %). Processed meats (93.9 %) and breakfast cereals/bars (65.7 %) showed particularly high warning prevalence. Nearly one-quarter (23.5 %) of unlabelled packaged foods had sodium levels within 5 % of the regulatory threshold—especially meat, sauces, and frozen meals—indicating strategic reformulation near cutoff values. Labeled products were more energy-dense and costlier per 100 g but cheaper per 1,000 kcal; notably, sugar-labelled snacks were 33 % cheaper per 100 g than unlabelled counterparts, underscoring affordability of less-healthy options.

Conclusion: Israel’s pioneering dual-FOPL policy has reshaped the retail food environment but reveals limited green-label uptake and widespread borderline sodium reformulation. Strengthening nutrient thresholds, monitoring compliance, and integrating fiscal or incentive measures could enhance policy impact and health equity. These findings provide the first objective baseline for national FOPL monitoring and contribute to global evidence on how labelling regulations influence food environments, equity, and consumer choice.

H. POLICIES AND ENVIRONMENTS

II-P-H.09

Resting Heart Rate for Global Health Surveillance? Insights from WHO STEPS and South Asia Biobank

A. Alshalla¹, T. Gonzales¹, J. Chambers², M. Mridha³, V. Jha⁴, G. Pradeepa⁵, A. Kasturiratne⁶, K. Irfan Khawaja⁷, S. Brage¹, South Asia Biobank Study Group

¹University of Cambridge, MRC Epidemiology Unit, Cambridge, United Kingdom, ²Nanyang Technological University, Lee Kong Chian School of Medicine, Singapore, Singapore, ³BRAC University, James P Grant School of Public Health, Dhaka, Bangladesh, ⁴Max Healthcare Institute, New Delhi, India, ⁵Madras Diabetes Research Foundation, Chennai, India, ⁶University of Kelaniya, Colombo, Sri Lanka, ⁷Services Institute of Medical Sciences, Lahore, Pakistan

Purpose: Resting heart rate (RHR) is a proxy for cardiorespiratory fitness, associated with cardiovascular disease (CVD) risk and mortality. Fitness is largely understudied in the global context, especially in non-Western populations. This study integrates the WHO-STEPS surveys with the South Asia Biobank (SAB) to answer the question of how RHR varies by person, place and time.

Methods: This cross-sectional study analysed data from WHO-STEPS (76 countries, n=326,560 adults) and SAB (4 South Asian countries, n=201,197). We describe RHR across age, sex, BMI, physical activity and other behaviours. Association analyses used generalized linear mixed models, clustered for country (WHO) or centre (SAB). Longitudinal trends were estimated from repeat cross-sectional surveys in 19 WHO countries.

Results: In WHO-STEPS, median RHR was 74bpm in men and 76bpm in women; in SAB, it was 70bpm in men and 79bpm in women. In WHO-STEPS, RHR in men was positively associated with age (65+: 1.019 [95% CI: 1.007, 1.030] vs. 25-44), obesity (1.059 [1.049, 1.070]), and inversely associated with meeting PA guidelines (0.987 [0.981, 0.993]); in women RHR was inversely associated with age (65+: 0.982 [0.971, 0.994]) and meeting PA guidelines (0.988 [0.983, 0.994]), and positively associated with underweight (1.013 [1.006, 1.020]) and obesity (1.013 [1.006, 1.020]). Relative to the Sub-Saharan Africa region, RHR was higher in Middle-East North Africa (men: 1.038 [1.029, 1.047], women: 1.019 [1.012, 1.026]) and South and South-East Asia (men: 1.053 [1.045, 1.061], women: 1.019 [1.012, 1.026]). Country-level longitudinal trends were modest only in men (-0.40 bpm/year). In SAB, associations with age, BMI group, and physical activity status were similar; in addition, RHR was higher in people with pre-existing metabolic disease (men: 1.038 [1.036, 1.041], women: 1.026 [1.024, 1.028]) and in June-August (men: 1.013 [1.009, 1.016], women: 1.008 [1.005, 1.010]).

Conclusion: RHR displays different associations with age in men and women but is universally higher in obese and non-active individuals. RHR appear stable year-on-year, potentially even declining slightly in men. In hot and humid climates, RHR appears to be higher in the most humid time of the year. Findings support incorporating RHR into routine health surveillance, with implications for reducing global CVD burden.

II-P-H.10

Nutritional Portrait of Processed Foods Prior to the Implementation of a Mandatory Front-of-Pack Nutrition Label in Canada

S. Pomerleau¹, D. Guillemette¹, I. Petitclerc¹, J. Perron¹, C.-J. Rhéaume¹, M.-È. Labonté¹, V. Provencher¹

¹Université Laval, INAF, Québec, Canada

Purpose: Starting January 1st 2026, Health Canada requires a nutrition symbol to be displayed on the front-of-pack of processed foods high in saturated fat, sugars, and/or sodium. To appropriately monitor changes in the quality of food products over time, it is first necessary to establish an overview prior to the implementation of this new regulation. In this study, the Food Quality Observatory aimed to determine the theoretical proportion of products that would carry the symbol before the regulation is implemented.

Methods: Nutritional information was gathered from the packaging of products in 15 processed food categories available in food stores in the province of Québec (Canada) in 2021-2025. Ready-to-eat breakfast cereals, sliced breads, luncheon meats, ready-to-serve soups, pizzas, granola bars, frozen meals, pasta sauces, yogurts and dairy desserts, sausages, cookies, crackers, salty snacks, processed cheeses as well as milk and plant-based drinks were analyzed.

Results: A total of 5844 products were collected, of which 60% would carry the symbol for at least one of the three nutrients of concern, 23% would carry it for two nutrients, and 0.4% for the three nutrients. Sodium was the nutrient with the largest proportion of products (38%) which would carry the symbol. Pizzas (99%), luncheon meats (96%) and sausages (89%) were the food categories for which the symbol for sodium would most often appear. The symbol

H. POLICIES AND ENVIRONMENTS

for saturated fat would be displayed on 32% of products. Pizzas (76%) and sausages (76%) were the categories that would most often carry the symbol for saturated fat. As for sugars, 14% of products would have to display the symbol, with cookies (58%) and granola bars (28%) being the categories that carried it most often.

Conclusion: This portrait provides an overview of the nutritional quality of food products prior to the implementation of the Health Canada regulation. It shows that 60% of the products studied have high levels of nutrients known to have adverse effects on health. This study generates important baseline data to monitor the nutritional quality of the food supply. Public health measures aimed at improving the food supply's quality must be prioritized.

II-P-H.12

Elevated Obesity Rates in UK Truck Drivers: Insights from a Socio-economically Matched Population Analysis

E. Gunner¹, S. Clemes¹, E. Petherick¹, E. Stamp¹, J. King¹

¹Loughborough University, Loughborough, United Kingdom

Purpose: Truck drivers face distinct occupational barriers to maintaining healthy lifestyles, including prolonged sitting, poor dietary options, restricted activity, and shift work, which may contribute to an elevated risk of obesity. Yet no studies have directly compared obesity prevalence or risk in this occupational group to a sample of the general UK population. This study aimed to compare obesity prevalence and risk between truck drivers and a matched sample from the Health Survey for England (HSfE), adjusting for socio-demographic factors, to inform targeted interventions and policies. We hypothesised that there would be a higher prevalence and relative risk of obesity in truck drivers.

Methods: The present study used UK male truck driver data (n=625) from existing research, including baseline data from the SHIFT UK randomised controlled trial and academic survey data. A combination of researcher-collected and self-reported BMI data were used to calculate the prevalence of overweight and obesity in drivers, self-reported BMIs were corrected for consistency with HSfE methods. Overweight and obesity prevalence and relative risks were compared between drivers and male participants from the 2019 HSfE (n=485), matched by age and socio-economic group (based on occupational category using the UK's National Statistics Socio-economic Classification system). Analyses were conducted using Pearson's chi-squared tests and multinomial logistic regression, stratified by age.

Results: Truck drivers were significantly more likely to have obesity in comparison to the HSfE sample (51.5% vs 34.0%, $p<0.001$), with a particularly large difference present in the 25-34 age group (45.8% vs 22.0%, $p<0.001$). Furthermore, truck drivers had a ~2.5 and ~4-fold increased risk of overweight and obesity, respectively, compared to the HSfE sample.

Conclusion: These results demonstrate that obesity prevalence and risk is greater in UK (English) truck drivers than in comparable men from the HSfE. This may relate to the occupational constraints that impact diet, physical activity, and sedentary behaviour. The high obesity prevalence in younger drivers is a particular concern as prolonged exposure to unhealthy working environments may exacerbate health risks. These findings highlight an urgent need for more robust approaches (including policy changes) to tackle obesity and improve health outcomes in this occupational group.

II-P-H.13

The Food Label Information and Price (FLIP) Database: Leveraging Big Data and AI to Advance Global Food Policy Research and Monitoring

M.R. L'Abbe¹, A. Schermerl¹

¹University of Toronto, Department of Nutritional Sciences, Toronto, Canada

Purpose: Developed in 2010 at the University of Toronto, the Food Label Information and Price (FLIP) database is an innovative, scalable, and internationally deployable branded food composition database designed to support nutrition research, food policy evaluation, and noncommunicable disease (NCD) prevention. FLIP enables countries to assess and monitor the nutritional quality of their food supply and evaluate the impacts of food policies such as nutrient reformulation targets, front-of-pack labelling, and children's marketing restrictions. This abstract presents FLIP's latest methodological advances in artificial intelligence (AI) and big-data analytics, highlighting its international reach, policy applications, and opportunities for global expansion.

Methods: FLIP integrates web-scraping and in-store data collection from major grocery retailers, capturing

H. POLICIES AND ENVIRONMENTS

approximately 230,000 branded food products in Canada and 74,000 products across 12 countries in Latin America (LAC), Africa, and Asia. Data are processed through a secure, cloud-based platform that employs optical character recognition, natural language processing, and machine learning algorithms to automate food categorization, nutrient profiling (e.g., FSAANZ, WHO, PAHO systems), and NOVA food processing classification. Manual validation complements automated quality control to maintain high accuracy and consistency across datasets. The FLIP framework's adaptable architecture supports linkages with dietary intake surveys, consumer mobile applications, and complementary data sources, enabling advanced nutrition research and evidence-based health policy development for NCD prevention.

Results: FLIP-Canada's automated processing achieves high accuracy in classifying products by category, nutrient profiling, and processing level, thereby reducing the cost and time traditionally required for manual coding. FLIP-LAC's repeated data collection cycles demonstrate the system's ability to monitor policy-relevant changes in sodium and trans fat content, and to evaluate compliance with PAHO and WHO nutrient targets. Ongoing collaborations demonstrate successful integration into national monitoring and food environment research.

Conclusion: FLIP represents a state-of-the-art methodological innovation in the use of AI and big data for food policy and nutrition surveillance. Its adaptability across contexts positions it as a critical tool for evidence-based policymaking worldwide. Future directions include expanding global data-sharing partnerships and refining algorithms for multilingual and cross-market analyses.

II-P-H.14

,Adverse Effects' of Health Promotion Regulations: The Case of Judgmental Food Product Labelling

O. Tamir¹, D. Menachem¹, T. Kolobov¹, S. Furman-Assaf¹, O. Baron-Epel²

¹Sheba Medical Center, Ramat Gan, Israel, ²Haifa University, Haifa, Israel

Purpose: Health promotion regulations are designed to influence public behavior and improve health outcomes. Despite their valuable positive impact on individuals and society, prior research suggest that they may also generate unintended and unexpected negative effects. The purpose of this presentation is to describe findings on the adverse effects of the judgmental food product labelling regulation (front-of-package green and red labels) implemented in Israel since January 2020. Identifying these effects enables a better understanding of cases in which the reform may be ineffective or even harmful.

Methods: A cross-sectional descriptive study using an online self-report questionnaire. Data were collected from 3,292 Israeli Jewish and Arab adults. The questionnaire addressed purchasing and consumption habits, perceptions of the food product labelling, and its impact.

Data were analyzed by subgroup (Jewish non-Orthodox, Jewish Orthodox, and Arab) using descriptive statistics, correlation coefficients, and comparison of proportions. Cronbach's alpha was calculated for the complex variables built from several items. Linear regression was applied to describe the relationships between the dependent and independent variables.

Results: Survey results revealed five major adverse effects:

1. Confusion about recommended foods due to misunderstanding of labels and their absence on certain products (62.7% of respondents);
2. Negative eating behaviors suggestive of disordered eating patterns (20%);
3. Negative emotions or aversion regarding the red-labeled products, associated with the stop-sign symbolism of the red color (14.5%);
4. Reduced purchasing of green-labeled products due to a misconception that they are more expensive (10.8%);
5. Disregard for labels due to lack of confidence in their scientific validity (5.5%).

These adverse effects were consistent among the sub-populations, with differences in magnitude linked to socio-demographic parameters.

Conclusion: Our results provide an evidential foundation to the previously unexplored adverse effects of the food labelling regulation in Israel. The negative effects appear to stem primarily from knowledge and comprehension gaps. Actions such as proactive education regarding the rationale for the regulation, the professional definitions according to which the labels were determined, the meaning of each label, and the meaning of their absence, may enhance the regulation's effectiveness, particularly when tailored to the characteristics of specific population groups.

H. POLICIES AND ENVIRONMENTS

II-P-H.15

Creation of a Neighborhood ACEs Index to Explore the Association between Parental Adverse Childhood Experiences and Children's Obesity

K. Schroeder¹, A. Shah^{2,3}, C. Lee⁴, J. Noll^{5,6}, D. Sarwer⁷

¹Temple University College of Public Health, Nursing, Philadelphia, United States, ²Cincinnati Children's Hospital Medical Center, Hospital Medicine, Cincinnati, United States, ³University of Cincinnati, Pediatrics, Cincinnati, United States, ⁴Temple University, Nursing; Epidemiology and Biostatistics, Philadelphia, United States, ⁵University of Rochester, Psychology, Rochester, United States, ⁶Mount Hope Family Center, Rochester, United States, ⁷Temple University, Social and Behavioral Sciences, Philadelphia, United States

Purpose: Research suggests that parents' adverse childhood experiences (ACEs) may increase their child's risk for obesity. However neighborhood environment's role in this association has not been explored – overlooking a key level of ecology relevant to obesity risk. Thus, the purpose of this study was to create a Neighborhood ACEs Index that capture the association between parent ACEs exposure and neighborhood characteristics, to be leveraged in a future study examining associations between parent ACEs, neighborhood characteristics, and children's obesity.

Methods: Research suggests that parents' adverse childhood experiences (ACEs) may increase their child's risk for obesity. However neighborhood environment's role in this association has not been explored – overlooking a key level of ecology relevant to obesity risk. Thus, the purpose of this study was to create a Neighborhood ACEs Index that capture the association between parent ACEs exposure and neighborhood characteristics, to be leveraged in a future study examining associations between parent ACEs, neighborhood characteristics, and children's obesity.

Results: The sample included N=1242 parents; N=237 experienced >3 ACEs. Most parents identified as (91%) female and either White (69%) or Black (31%), with an average age of 33±8 years. Every one unit increase in Neighborhood ACEs Index was associated with 1.15 times greater odds of high parent ACEs (95% CI: 1.05, 1.30). Neighborhood-level health risk factors such as less healthy food environment, worse supermarket access, more neighborhood poverty, and more crime demonstrated strong associations with parent ACEs (e.g., were in the upper 50%tile of index weights).

Conclusion: Children whose parents have a history of high ACEs live in neighborhoods with more health and obesity risk factors. This suggests neighborhood environment should be explored as a contextual factor when intervening to address intergenerational ACEs-obesity associations.

II-P-H.17

Food Pantries and their Role Addressing Food Insecurity across Five Post-secondary Campuses Serving Minoritized Students in the United States: A Mixed-methods Study

T.Z. Nobari¹, E. Grijalva-Martinez², A. Lederer³, D. Rose⁴, A. Galvez⁵, M. Knapp⁶, M.P. Chaparro⁷

¹California State University, Fullerton, Public Health, Fullerton, United States, ²University of Washington, Seattle, United States, ³Indiana University School of Public Health-Bloomington, Applied Health Science, Bloomington, United States, ⁴Tulane University School of Public Health & Tropical Medicine, Nutrition, New Orleans, United States, ⁵Lehman College, Latin American and Latino Studies, Bronx, United States, ⁶Xavier University of Louisiana, Public Health Sciences, New Orleans, United States, ⁷University of Washington School of Public Health, Health Systems and Population Health, Seattle, United States

Purpose: Food insecurity is highly prevalent among post-secondary students in the United States (U.S.), particularly among students of minoritized backgrounds. Post-secondary institutions can play an important role in addressing food insecurity, and many have established campus food pantries to serve their students. The purpose of this study was to assess campus food pantries' accessibility and food offerings as well as students' perceptions about these pantries in five U.S. post-secondary institutions serving primarily minoritized students across three U.S. states.

Methods: Food pantries in each campus (total n=5) were assessed twice between Fall 2024-Spring 2025 with an adapted version of the Healthy Food Pantry Assessment Tool, including 8 domains: Accessibility, Fruits and Vegetables, Protein, Eggs and Dairy, Grains, Beverages, Snacks, and Specialty Foods. A scoring protocol was developed to reflect pantry accessibility (e.g., opening days/hours, frequency students can use) and food offerings' availability, variety, and nutritional value, with a maximum possible total score of 85. Scores obtained from the two measurements within each campus were averaged. In addition, in-depth interviews were conducted with students in each campus (total n=34) to assess students' perceptions of their campus food pantries on similar domains as those captured in the

H. POLICIES AND ENVIRONMENTS

quantitative assessment. Thematic analysis of the interviews is ongoing.

Results: Food pantry scores ranged from 27 to 46 (out of 85 max) across the five campuses. Highest scores across campuses were obtained in the Accessibility (range 6.5 to 10, out of 16 max) and Grains (range 1.3 to 7.5, out of 9 max) domains, while the lowest scores were obtained in the Eggs and Dairy domain (range 2 to 2.8 out of 9 max). All food pantries offered at least one food item in each of the food categories (*availability* sub-domain), with substantial variability in the *variety* and *nutritional value* sub-domain scores. Qualitative results obtained from in-depth interviews' thematic analyses will be integrated with the quantitative results.

Conclusion: Food pantries are an important tool to address food insecurity among post-secondary students. Our quantitative results suggest that campus food pantries' food offerings could be improved, particularly in terms of variety and nutritional value.

II-P-H.18

Assessment and Benchmarking of the Food Industry'S Voluntary Commitments and Practices for Addressing Malnutrition in South Africa

C. Klinger^{1,2}, E.C. Okanmelu^{1,2}, D. Rincón Camargo^{1,2}, C. Meyer^{1,2}, M. Nkurunziza³, G. Sacks⁴, L. Vanderlee⁵, P. von Philipsborn^{6,1,2}, E.A. Rehfuess^{1,2}, P. Delobelle^{7,8}

¹LMU Munich, Chair of Public Health and Health Services Research, Institute for Medical Information Processing, Biometry and Epidemiology, Faculty of Medicine, Munich, Germany, ²Pettenkofer School of Public Health, Munich, Germany, ³University of the Western Cape, School of Public Health, Bellville, South Africa, ⁴Deakin University, Global Centre for Preventive Health and Nutrition, Geelong, Australia, ⁵Université Laval, École de Nutrition, Centre NUTRISS, Québec, Canada, ⁶University of Bayreuth, Chair of Public Health Nutrition, Faculty of Life Sciences, Kulmbach, Germany, ⁷University of Cape Town, Chronic Disease Initiative for Africa, Cape Town, South Africa, ⁸Vrije Universiteit Brussel, Department of Public Health, Brussels, Belgium

Purpose: South Africa faces high prevalences of both under- and overnutrition. An important driver of this so-called double burden of malnutrition are food environments dominated by the supply and marketing of unhealthy foods. The food industry plays a major role in shaping food environments and diets through its commercial actions. The aim of this work was to identify areas where food and beverage manufacturers, supermarkets and quick-service restaurants operating in South Africa demonstrate leadership in promoting healthier food environments and offer opportunities for improvement, particularly with regard to addressing and preventing all forms of malnutrition.

Methods: We applied the BIA-Obesity tool (Business Impact Assessment on Obesity and Population-level Nutrition) developed by INFORMAS, a global network of public-interest organizations and researchers. First, we adapted the tool to the South African context by removing non-applicable indicators and by adding an additional, seventh domain on the double burden of malnutrition. Publicly available policies, statements, and guidelines of included companies were collected between February 2024 and June 2025 and verified and/or supplemented by company representatives through direct feedback on the assessment sheet and/or semi-structured interviews. Company commitments and practices were then assessed against industry and public health benchmarks, and according to their comprehensiveness, specificity, and transparency. Scores were weighted to produce an overall score out of 100, and tailored recommendations were developed for each company.

Results: We selected 29 companies for inclusion in the assessment, based on market share (Euromonitor, 2022): 15 food and non-alcoholic beverage manufacturers, 4 supermarket chains and 10 quick-service restaurant chains. Overall, companies showed strengths in the domains of corporate strategy, disclosure of relationships with external organizations, and addressing the double burden of malnutrition. Potential for substantial improvement was identified in the areas of product formulation, nutrition labelling, promotion practices, as well as product pricing, availability and positioning.

Conclusion: Addressing the double burden of malnutrition in South Africa requires a multifaceted approach, where the active engagement of the food industry in shaping healthy food environments is essential. The assessed companies should prioritize implementing the identified recommendations to enhance their contribution to reducing under- and overnutrition in South Africa.

II-P-H.19

Designing Mandatory Sodium Reduction Targets in a Small Economy: Lessons from Uruguay

G. Ares¹, V. Natero², F. Alcaire¹

¹Universidad de la República, Facultad de Química, Montevideo, Uruguay, ²Universidad de la República, Escuela de Nutrición, Montevideo, Uruguay

Purpose: Food reformulation is widely recognized as a cost-effective strategy to reduce sodium consumption and improve public health. Although mandatory sodium targets are among the most effective approaches to enhance compliance, they may also have trade implications, particularly for small open economies dependent on food imports. This presentation highlights lessons from the design of mandatory sodium reduction targets in Uruguay, a small South American country. Specifically, the study aimed to (i) assess the sodium content of national and imported food products available in the Uruguayan market, (ii) evaluate their compliance with regional sodium reduction benchmarks, and (iii) estimate the potential public health and trade impacts of alternative policy scenarios.

Methods: Sodium content information was extracted from food labels of 4,719 packaged products collected in nine supermarkets across Uruguay in 2022. Products were classified as national or imported and compared against the 2021 Pan American Health Organization (PAHO) sodium targets. Additionally, modelling analyses estimated potential reductions in sodium intake among Uruguayan children under different implementation scenarios, ranging from full adoption of PAHO targets to more selective, trade-sensitive approaches.

Results: Results showed that Uruguay is lagging behind regional sodium reduction benchmarks in most product categories. Meeting PAHO targets would require sodium reductions exceeding the 15% perceptibility threshold for salty taste in a large proportion of products, potentially affecting consumer acceptance. Although sodium levels did not differ consistently between national and imported items, 56.4% of imported products would be non-compliant if PAHO targets were applied as mandatory limits. Modelling indicated that full implementation of the targets could reduce sodium intake among children by an average of 166 mg/day (24.7% of sodium intake from processed and ultra-processed products), while a selective, trade-sensitive approach would yield a smaller reduction of 68 mg/day (10.1%).

Conclusion: These findings underscore both the public health benefits and trade challenges of implementing sodium reduction policies in Uruguay. Tailoring regional benchmarks to national market conditions and prioritizing the food categories that contribute most to sodium intake could improve policy feasibility and ensure meaningful population-level reductions in sodium consumption.

II-P-H.23

Examining Park Quality and Features in Relation to Physical Activity in Low-income Neighborhood Parks

H. Hong^{1,2}, A. Dunlap^{1,2}, R.L. Thompson^{1,2}, K.E. Wyka^{1,2}, K.R. Evenson³, L.E. Thorpe^{4,2}, T.T.-K. Huang^{1,2}

¹City University of New York Graduate School of Public Health and Health Policy, Center for Systems and Community Design, New York, United States, ²NYU-CUNY Prevention Research Center, New York, United States, ³University of North Carolina-Chapel Hill Gillings School of Global Public Health, Department of Epidemiology, Chapel Hill, United States, ⁴New York University Grossman School of Medicine, Department of Population Health, New York, United States

Purpose: While urban parks may promote physical activity (PA), park quality and features may play an important role in shaping active behaviors. In this study, we developed a Park Quality Index (PQI) derived from the Community Park Audit Tool (CPAT) and examined the association between park quality, park features, and changes in PA levels among park users following park renovations.

Methods: Data was collected as part of the Physical Activity and Redesigned Community Spaces (PARCS) study, a longitudinal study evaluating citywide park renovations in low-income New York City neighborhoods. A total of 54 parks were included, with 33 renovated intervention sites and 21 control sites in sociodemographically-matched neighborhoods. Park quality was assessed across four domains: activity area, infrastructure, safety concerns, and aesthetics. The overall PQI was calculated as the sum of the normalized scores with equal weights (0.25) assigned to each category. PA was measured using the System for Observing Play and Recreation in Communities (SOPARC), where trained researchers recorded the number of individuals engaging in sitting, standing, walking, or vigorous activity during park scans before and one year after renovations were completed (between 2016 and 2022). Changes

H. POLICIES AND ENVIRONMENTS

in PA over time were dichotomized as either an increase or no change/decrease.

Results: PQI varied across study parks (range: 24.4-95.8), where intervention parks showed significantly higher PQI than controls, indicating better quality [mean (SD) intervention: 66.1 (16.3), control: 51.4 (15.3), $p=0.001$]. Among the intervention sites, a higher activity score was observed in parks with increased vigorous activity. Both the presence of an open/green space and the space being in good condition were associated with an increase in sitting and vigorous activity. Lighting was also associated with increased sitting and vigorous activity, but parks with moderate lighting (25–75% lit) showed the largest increase. Intervention parks with artistic features showed a marginal increase in vigorous activity.

Conclusion: CPAT-derived PQI effectively captured renovation-driven improvements in park environments and was associated with increased PA. Enhanced park quality, especially in open/green space, encouraged active use. These findings emphasize the importance of targeted park investments to promote park-based PA in low-income urban communities.

II-P-H.24

Neighborhood Park Improvements as a Necessary Precondition for the Association between Park Use Duration and Adult Physical Activity

R.L. Thompson^{1,2,3}, K.R. Evenson⁴, K.E. Wyka^{1,3}, L.E. Thorpe^{5,3}, G.D. Johnson^{2,1}, T.T.-K. Huang^{1,3}

¹City University of New York Graduate School of Public Health and Health Policy, Center for Systems and Community Design, New York, United States, ²City University of New York Graduate School of Public Health and Health Policy, Department of Environmental, Occupational, and Geospatial Health Sciences, New York, United States, ³NYU-CUNY Prevention Research Center, New York, United States, ⁴University of North Carolina-Chapel Hill Gillings School of Global Public Health, Department of Epidemiology, Chapel Hill, United States, ⁵New York University Grossman School of Medicine, Department of Population Health, New York, United States

Purpose: Inadequate physical activity (PA) elevates chronic disease risk in low-income urban populations. Neighborhood parks may support PA, but effects likely depend on park quality and individual use patterns. This study examined whether citywide park renovations under NYC's Community Parks Initiative were associated with changes in adult PA in low-income neighborhoods and whether associations between park use and PA changes differed for residents near renovated versus control parks.

Methods: A quasiexperimental prospective cohort study (2016-2022) was conducted in neighborhoods surrounding 31 renovated and 21 matched control parks. Participants included 344 adults living ≤ 0.3 miles of a park (186 intervention, 158 control). Outcomes were accelerometry-based PA measures collected pre and postrenovation: vector magnitude per minute (VMPM) and minutes/day of sedentary, light, and moderate-to-vigorous PA. Surveys assessed self-reported typical frequency and duration of park visits. Linear mixed-effects difference-in-difference models estimated associations between renovations and changes in PA (post-pre); interaction models examined associations of park use with PA changes in intervention vs. control groups.

Results: Changes in PA were not significantly different between intervention and control groups. However, in the intervention group, each additional 60 minutes spent at a study park on weekdays was associated with 18.0 more minutes of light activity/day (95% CI 4.7, 31.3), and each additional 60 minutes spent at the study park on weekend days corresponded to 19.0 more minutes of light activity/day (95% CI 8.1, 29.9) and a 54.1-unit increase in VMPM/day (95% CI 7.5, 100.7). Intervention participants who reported visiting their study park ≥ 30 minutes on a weekend day experienced a 140.0-unit greater increase in VMPM (95% CI 52.7, 227.2) and a 61.1-minute larger decrease in sedentary time (95% CI -108.8, -13.3) compared to those with shorter visit durations. No associations between park use duration and changes in PA were observed in the control group.

Conclusion: Park renovations alone were not associated with increased PA, but longer duration of visits at renovated—but not control—parks were associated with increased total PA volume, increased light activity, and decreased sedentary time. High-quality park environments may be a necessary pre-condition to the benefits of park use on adult PA.

H. POLICIES AND ENVIRONMENTS

II-P-H.25

Contributions of Park-based Activities to Overall Physical Activity among Renovated Park Users in Low-income Neighborhoods: Variations by Race/Ethnicity and Sex

R.L. Thompson^{1,2}, L.D. Olivera León^{1,2}, H. Hong^{1,2}, J. Maffei^{1,2}, K.E. Wyka^{1,2}, T.T.-K. Huang^{1,2}

¹City University of New York Graduate School of Public Health and Health Policy, Center for Systems and Community Design, New York, United States, ²NYU-CUNY Prevention Research Center, New York, United States

Purpose: Urban parks may promote physical activity (PA); however, little is known about whether renovated urban parks contribute to overall PA similarly across diverse sociodemographic groups. In this cross-sectional study, we examined associations between park-based activities and overall PA among adults living near recently renovated parks in low-income New York City (NYC) neighborhoods, with particular attention to differences by race/ethnicity and sex.

Methods: A total of 1,336 adult survey respondents who reported past-month use of a renovated park within 0.5 miles of their residence were included. Surveys captured usual participation in activities at the renovated park (i.e., walking, exercising, taking children to the playground/park, relaxing, socializing, volunteering) and self-reported PA level during visits. The outcome, overall past-week PA, was measured in metabolic equivalent of task (MET)-minutes using the International Physical Activity Questionnaire and log-transformed prior to analysis. Linear regression models estimated associations of park-based activities and park-based PA levels with log(MET-minutes) of overall PA in the full sample and stratified by race/ethnicity and sex.

Results: In the full sample, park-based activities explained 5.4% of the variability in overall PA of past-month renovated park users; self-reported park-based PA level explained 5.2% of the variability. Compared to past-month park users who did not engage in these activities, those who reported exercising at the study park had 47% higher overall PA and those who reported walking had 33% higher overall PA, while those who reported volunteering had 26% lower overall PA, after confounder adjustment. Activities at renovated parks explained more variability in overall PA among males (6.3%) compared with females (5.1%), and among minority groups (Latino/as = 6.5%, Blacks = 6.8%, other race/ethnicity = 11.2%) compared with Whites (4.3%).

Conclusion: Among adults with past-month renovated park use in low-income NYC neighborhoods, park-based activities explained a significant proportion of the variability in overall PA, with stronger contributions among minorities and males. These findings highlight the importance of considering sociodemographic differences when assessing the role of renovated urban parks in promoting PA and suggest that investments in high-quality green spaces may be particularly impactful for minority groups facing disproportionate barriers to PA.

II-P-H.26

A Natural Experiment Assessing the Impact of Protected Bike Lanes Near Schools on Walking and Biking in Phoenix, AZ, USA

A. Poulos¹, K. Wilson², P. Hodges Kulinna³, M. Schulte⁴, U. Abubakar Hassan¹, J. Kim³, A. Oyeyemi¹

¹Arizona State University, College of Health Solutions, Phoenix, United States, ²University of Arizona, Cancer Center, Tucson, United States, ³Arizona State University, Mary Lou Fulton College for Teaching and Learning Innovation, Tempe, United States, ⁴Southwest Autism Research and Resource Center, Phoenix, United States

Purpose: Active transportation to school (ATS) provides physical activity and supports individual and environmental health; yet only ~10% of U.S. youth walk/bike to school. Infrastructure improvements like protected bike lanes can promote ATS ; however, few experimental studies have examined changes in youth travel behavior. In this natural experiment, we hypothesized that an innovative city-driven road renovation replacing two car lanes with protected bike lanes would increase walking/biking and perceived safety.

Methods: This natural experiment objectively measured walking/biking at seven intersections near two public elementary schools in Phoenix, AZ (U.S.), adjacent to a bike lane renovation, and parent-reported school travel and safety perceptions (N=1792021; 892024). Changes in travel behavior were compared to 28 area schools with no infrastructure modifications. Objective walking/biking were measured by observational counts over four days, one hour before and after school start/end, and parent reports were assessed by survey1 in September one year prior (2021) and after (2024) the bike lane installation. Average counts of walkers/bikers over all days and intersections and changes over time were assessed using Poisson generalized linear models. Changes in survey-reported ATS,

H. POLICIES AND ENVIRONMENTS

defined as walking/biking 1+ day/week, and safety perceptions were assessed using chi-square tests and Wilcoxon signed-rank tests, respectively, among the whole sample and those living within 0.5 miles.

Results: The average number of bicyclists crossing intersections at the intervention site during the school commute increased 750%, from 2-17. The average number of pedestrians increased 57%, from 42-66. No statistically significant differences in parent-reported walking/biking to (15.9%2021 and 15.5%2024) or from (13.5%2021 and 12.1%2024) school were found, including by distance. Rates of walking/biking among comparison schools were lower and did not change significantly over time (7.0%2021 and 7.8%2024). Parents' desire for children to walk/bike decreased; however, perceptions of school encouragement and children having fun increased. Parents reported increases in lack of crossing guards, too much violence/crime, and weather preventing walking/biking.

Conclusion: Protected bike lanes increased walking/biking near schools; however, parent safety concerns persisted. This underscores the importance of coupling infrastructure improvements with family- and community-based strategies to address safety perceptions and foster supportive environments.

II-P-H.27

Stressful Life Events after a Natural Disaster, Housing Instability, & Nutrition Insecurity among Residents of New Orleans, LA

C. Singleton¹, M. Muñoz¹, D. Gartner¹, A. Arcot¹, K. O'Mally¹, D. Rose¹, M. Fuster¹

¹Tulane University, Department of Social, Behavioral, and Population Sciences, New Orleans, United States

Purpose: Natural disasters (e.g., hurricane, tornado, flash flood) can be mentally, physically, and financially devastating for individuals and families. This study aimed to examine associations between prior experiences of stressful life events after a natural disaster and recent reporting of housing instability and nutrition insecurity among residents of a disaster-prone city – New Orleans, LA, USA.

Methods: We analyzed preliminary data from an ongoing evaluation of post-disaster food aid in New Orleans. As of February 2026, 199 residents (mean age: 52.4; 70.8% female; 69.9% Black; 30.6% ≥ college degree) have completed our comprehensive cross-sectional survey. Each respondent self-reported their demographics and completed 1-item screening questions for housing instability (prior 3 months) and nutrition insecurity (prior 12 months). In addition, they completed an 11-item screener for stressful life events after a natural disaster, such as property loss, job loss, inability to obtain safe food & water, inability to obtain personal items (e.g., medication, diapers), physical injury/illness, loss of a friend/family member, and witnessing a major crime. We ran multivariable logistic regression models to determine if the total number of stressful life events was associated with odds of screening positive for housing instability and nutrition insecurity.

Results: Approximately 38.1% and 53.3% of respondents screened positive for housing instability and nutrition insecurity, respectively. Mean number of stressful life events reported was 2.93 (±2.6), with 42.7% of respondents reporting ≥3 events. After adjusting for age, sex, race/ethnicity, and education, total number of events (AOR: 1.29; 95% CI: 1.13-1.48) and reporting ≥3 events (AOR: 2.73; 95% CI: 1.42-5.36) were associated with higher odds of housing instability. Total number of events (AOR: 1.11; 95% CI: 0.98-1.25) and reporting ≥3 events (AOR: 1.81; 95% CI: 0.95-3.45) were marginally associated with nutrition insecurity. We will finalize these analyses after data collection concludes.

Conclusion: Reporting stressful life events after a natural disaster is associated with housing instability and marginally associated with nutrition insecurity among New Orleans residents. This underscores the impact natural disasters can have on stability and nutritional well-being.

II-P-H.28

Socio-economic, Educational, Gender, and Age Disparities in Overweight in Colombia

Y.P. Rueda-Guevara¹

¹University of Pennsylvania, Demography and Sociology, Philadelphia, United States

Purpose: This study aimed to estimate how socioeconomic strata, educational level, gender, age, and other social determinants of health are associated with overweight in Colombian adults. Using the most recent National Survey of the Nutritional Situation (ENSIN 2015), it addresses a key evidence gap by jointly examining individual and household characteristics, as well as regional and urban-rural differences, to identify population groups at higher risk.

H. POLICIES AND ENVIRONMENTS

Methods: A cross-sectional, descriptive study was conducted using secondary data from a nationally representative, multistage, stratified household survey. The analytical sample included 73,659 adults aged 18–64 years with valid anthropometric data, excluding pregnant women, individuals with implausible measurements, and underweight adults. Overweight was defined as BMI ≥ 25 kg/m² (overweight and obesity) versus BMI < 25 kg/m². Independent variables covered sociodemographic and household characteristics. Survey-weighted descriptive analyses, chi-square tests, and multivariate logistic regression models were performed. The final model was selected using the BIC and results are reported as odds ratios with 95% CI.

Results: The prevalence of overweight was 57.86% (38.72% overweight, 19.14% obesity). The probability of being overweight increased steadily with age, reaching an OR ≈ 4.2 among adults aged 58–64 years compared with those aged 18–22 years. Women had higher odds of overweight than men (OR 1.27). Compared with Bogota, residing in Orinoquia–Amazonia (OR 1.74), Pacific (OR 1.57), Atlantic (OR 1.49), Central (OR 1.29), and Eastern (OR 1.27) regions was associated with higher odds of overweight. Rural residence was associated with lower odds (OR 0.90) compared with urban areas. Higher wealth quartiles were positively associated with overweight, while being single (OR 0.59) or divorced (OR 0.76) was associated with lower odds compared with being married.

Conclusion: Overweight in Colombia shows marked age, gender, socioeconomic, marital, and territorial disparities, suggesting a clear social stratification of nutritional risk. These findings underscore the need for differentiated prevention and control strategies that account for regional context, urban–rural setting, and social determinants, and that guide the design of targeted interventions and public policies to reduce overweight and its health and economic consequences.

II-P-H.29

Measuring Differences in Built Environment for Physical Activity Promotion: A Scoping Review of Methods

A.A. Lungu¹, D. Fuller², Y. Kestens³, T. Barnett¹

¹McGill University, Family Medicine, Montreal, Canada, ²University of Saskatchewan, Community Health & Epidemiology, Saskatoon, Canada, ³Université de Montréal, School of Public Health, Montreal, Canada

Purpose: Although the built environment (BE) is recognized as an important determinant of physical activity, longitudinal evidence on how BE changes influence uptake and maintenance remains limited, partly due to inconsistent measurement approaches. We conducted a scoping review of the peer-reviewed public health literature to synthesize methods used to measure and operationalize BE change; relevance to physical activity was a primary consideration.

Methods: Guided by a librarian, Medline, Embase and Scopus were searched (1967–2025) using salient keywords (e.g. *neighbourhood, improvement, longitudinal*). Inclusion criteria were longitudinal studies, and minimally one reported health outcome. Studies of ambient environmental exposures, food environments, subjective methods, and highly specific natural experiments were excluded. A total of 1958 studies were screened; 50 underwent full-text review. Extracted data included study characteristics, exposure definitions and indicators, spatial framing, change operationalization, analytic methods, validation and sensitivity analyses, and key findings on BE change. A descriptive synthesis was conducted, including tabulation of study features and narrative comparison of exposure and change measurement approaches.

Results: Sixteen studies were included, 15 of which were from high-income countries. Studies included between 2 and 5 exposure measurement time points. Exposures included elements of walkability (10/16), parks and green space (8/16), and recreational facilities (4/16) defined within residential spatial buffers ranging from 400m to 1600m. Methods for calculating change varied widely. Many studies subtracted the scores at follow-up from baseline, while some studies weighted change categories, and others created composite scores based on upward or downward mobility across defined change categories. Street-level walkability improvements were modestly associated with physical activity, while increases in park area and upgrades to recreational features generally showed null associations. Subgroup analyses suggested greater benefits for urban residents, and lower socioeconomic groups. Few studies reported validation of exposure measures or conducted sensitivity analyses testing alternative spatial scales or change definitions.

Conclusion: These findings provide an initial descriptive synthesis of how BE change has been operationalized in health studies and applied to physical activity. Ongoing analyses assessing methodological strengths and limitations will be presented, with the goal of informing future environmental interventions to support physical activity and equitable urban development.

H. POLICIES AND ENVIRONMENTS

Moving in Nature Matters: Associations between Outdoor Physical Activities and Pro-environmental Behaviours

E. Rivera¹, K. Chen², S. Schoeppe³

¹Central Queensland University, School of Health, Medical and Applied Sciences, College of Science and Sustainability, Melbourne, Australia, ²Central Queensland University, School of Health, Medical and Applied Sciences, Appleton Institute, Physical Activity Research Group, Rockhampton, Australia, ³Central Queensland University, School of Health, Medical and Applied Sciences, Appleton Institute, Physical Activity Research Group, S.P.O.R.T. Research Cluster, Rockhampton, Australia

Purpose: Studies have shown that being active outdoors is not only associated with improved health and wellbeing but also with engagement in pro-environmental behaviours. However, it is unclear whether these co-benefits apply to outdoor physical activities undertaken in natural versus built environments. This study examined associations between outdoor physical activities undertaken in natural versus built environments and people's engagement in pro-environmental behaviours.

Methods: In 2025, a cross-sectional study using an anonymous online survey was conducted among 376 Australian adults recruited via community organisations and social media. Participants self-reported their sociodemographic characteristics, outdoor physical activities undertaken in natural environments (e.g., forest, beach, wetlands) and built environments (e.g., residential neighbourhood, downtown city areas), as well as their engagement in pro-environmental behaviours (e.g., active transport, picking up litter outdoors, recycling, reusing shopping bags, using solar, being vegetarian). Multiple linear regression was conducted to analyse associations between outdoor physical activities undertaken in natural versus built environments (i.e., predictors) and engagement in pro-environmental behaviours (i.e., outcomes). The analyses were adjusted for confounding factors (i.e., age, gender, ethnicity, education, residential remoteness, employment status, and income).

Results: Participants' mean age was 44 years, and most of them were female (66%), Caucasian (88%), lived in a major city (63%), and had a higher education (69%). Engagement in outdoor physical activities in natural environments significantly predicted engagement in more pro-environmental behaviours ($B = 0.53$, $p < .001$, 95% CI [0.32, 0.75]). In contrast, participation in outdoor physical activities in built environments was not associated with engagement in pro-environmental behaviours ($B = 0.27$, $p = .090$, 95% CI [-0.04, 0.58]).

Conclusion: The findings suggest that promoting outdoor physical activities in natural environments may positively impact people's environmental stewardship. Hence, promoting outdoor physical activities in nature may be a promising strategy to improve human and planetary health.

II-P-H.31

Physical Activity Differences Between Telework and Office Work in Combat Support Service Administrative Personnel

M. Polspoel^{1,2}, T. Reilly³, P. Calders¹, D. Van Tiggelen^{4,1}

¹Ghent University, Department of Rehabilitation Sciences, Ghent, Belgium, ²Queen Astrid Military Hospital, Center for Physical Medicine and Rehabilitation, Brussels, Belgium, ³Canadian Forces Morale & Welfare Services, Ottawa, Canada, ⁴Belgian Defence, Medical Component Command, Brussels, Belgium

Purpose: Telework has become a permanent feature of modern work arrangements, yet its impact on physical activity (PA) remains incompletely understood. This study examined differences in accelerometer-measured PA between telework and office days using a within-person design, with particular attention to commuting contributions and diurnal patterns.

Methods: Seventy-four military office workers (64 hybrid workers, 10 office-only workers; mean age 39.2±8.4 years; 58.1% male) wore wrist-worn ActiGraph GT9X accelerometers across three measurement periods, spread over a period of three months. During each measurement period, the office workers wore the ActiGraph GT9X continuously for 14 days while recording work location daily. Raw acceleration data were processed to derive the Euclidean Norm Minus One (ENMO) metric. Linear mixed-effects models compared daily PA outcomes between telework and office days in hybrid workers, with secondary analyses excluding commuting time and restricting observation windows to core working hours (07:00–15:45).

Results: Hybrid workers exhibited substantially lower PA on telework days than office days (mean ENMO: 29.8 vs. 35.2

H. POLICIES AND ENVIRONMENTS

mg; difference: -5.4 mg, 95% CI: -6.8, -4.0; Cohen's $d=0.62$). Light-intensity PA showed the largest deficit (-42.4 min/day, 95% CI: -51.2, -33.6; $d=0.84$). Excluding commuting reduced the ENMO difference by 48.1% (to -2.8 mg) and the light PA difference by 51.7% (to -20.5 min/day). During work hours only (07:00–15:45, commuting excluded), telework remained associated with lower ENMO (-2.1 mg, 95% CI: -3.3, -0.9) and light PA (-18.3 min/day, 95% CI: -25.8, -10.8).

Conclusion: Telework is associated with reduced daily PA, driven primarily by eliminated commuting and secondarily by lower workplace-based light-intensity activity. Hybrid work policies should consider strategies to compensate for commuting-related activity loss.

II-P-H.32

Public Support for UK Advertising Restrictions for Less Healthy Foods on Television and Online Prior to Implementation: Cross-sectional Analysis of the International Food Policy Study

É. Demers-Potvin¹, M. White¹, L. Vanderlee^{2,3}, C. White⁴, D. Hammond⁴, J. Adams¹

¹University of Cambridge, Institute of Metabolic Science Epidemiology, Cambridge, United Kingdom, ²Université Laval, Centre NUTRISS - Nutrition, Santé et Société, Québec, Canada, ³Université Laval, École de Nutrition, Québec, Canada,

⁴University of Waterloo, School of Public Health Sciences, Waterloo, Canada

Purpose: In January 2026, the UK government implemented restrictions on advertising unhealthy foods on TV between 5:30-9:00pm and online at all times. We examined public support for the advertising restrictions prior to implementation and differences in support across sociodemographics.

Methods: Data were from the 2024 International Food Policy Study, an annual cross-sectional web-based survey conducted among adults in five countries including the UK. Respondents ($n=3,929$) were asked whether they support, are neutral or oppose a ban on advertising unhealthy foods: 1. Online; 2. On TV before 9pm. Descriptive statistics examined the weighted percentages of respondents who supported, were neutral or opposed the advertising restrictions. Weighted multinomial logistic regression models (one for each policy) examined whether policy support differed across sociodemographics.

Results: Half of respondents supported the online restrictions, 37% were neutral and 14% were opposed. For the TV restrictions, 56% supported, 31% were neutral and 12% opposed. Women were more likely than men to support than oppose the online (RRR=1.31, 95%CI: 1.06-1.61) and TV (RRR=1.44, 95%CI: 1.15-1.81) restrictions. Older respondents (vs 18-29 years) were more likely to support than oppose the online (e.g., 60+ years: RRR=4.97, 95%CI: 3.56-6.95) and TV restrictions (e.g., 60+ years: RRR=6.54, 95%CI: 4.57-9.35). Those aged 60+ (vs 18-29 years) were also more likely to be neutral than oppose the online (RRR=1.51, 95%CI: 1.09-2.11) and TV restrictions (RRR=1.55, 95%CI: 1.07-2.25). Respondents with high educational attainment (vs low) were more likely to support than oppose the online (RRR=1.34, 95%CI: 1.03-1.73) and TV restrictions (RRR=1.61, 95%CI: 1.23-2.12). Those with medium educational attainment (vs low) were more likely to support (RRR=1.45, 95%CI: 1.08-1.96) than oppose the TV restrictions.

Conclusion: Few respondents opposed advertising restrictions on unhealthy foods in the UK, suggesting public opposition was not a barrier to policy implementation. Sociodemographic differences could inform targeted messaging to increase support in less supportive groups.

II-P-H.33

Upstream Challenges, Downstream Governance. How Dutch Municipalities Navigate Upstream Drivers of Unhealthy Food Environments

J. Vastenhoud¹, L. Hagenaars¹, K. Stronks¹

¹Amsterdam UMC, Public and Occupational Health, Amsterdam, Netherlands

Purpose: Unhealthy food environments are a key driver of non-communicable diseases such as obesity and type 2 diabetes. A highly concentrated food sector, corporate lobbying power, and profit-driven food production systematically shape unhealthy food environments. This study investigates how Dutch municipalities participating in the City Deal Network deal with these upstream influences in their attempts to improve local food environments. Public health's tradition of focusing on individual behavior change and local government's primary focus on social care, leaves municipalities ill-positioned to address food environments in relation to macro-economic food systems. Torfing's governance framework, which distinguishes Classic Public Administration (CPA), New Public Management

H. POLICIES AND ENVIRONMENTS

(NPM), and New Public Governance (NPG), provides the analytical lens to examine how municipalities navigate this position. The unique intersection of macro-economic food system dynamics and local governance around food environments make a valuable contribution to our understanding of food policy governance.

Methods: We analyzed policy documents from 10 municipalities participating in the City Deal Network, including health policies, food strategies, coalition agreements, and council motions. Using a hybrid coding approach. Torfing's framework provided an initial deductive coding scheme, which was supplemented inductively with empirical patterns that extended beyond its categories. These codes revealed overarching themes about how municipalities used different governance models to address food environments.

Results: Preliminary findings suggest four themes. Municipalities operated with limited formal policy space, and their CPA output predominantly reflected authority and regulatory instruments municipalities sought and not yet processed. NPG was the dominant form of operation where collaborative networks were also used to pursue outcomes not typically associated with NPG logic. Across all governance dimensions, accountability was directed mostly upward toward legal and scientific authority.

Conclusion: Many municipalities realized that addressing food environments required more authority and legal instruments to oppose adverse influences of the food sector. In the absence of binding measures, municipalities collectively lobbied for more authority and engaged in network building, while also resorting to individual behavior change as an alternative output. This study underscores that aligning municipal responsibilities with proportional authority is a prerequisite for effective food environment governance.

II-P-H.34

Beyond the Plate: Diet Quality and Ultra-processed Food Consumption in Belgium

I. Moyersoen¹, K.T. Belete², T. Lebacqz¹, M.S. Vasques¹, N. Berger^{1,1}

¹Sciensano, Epidemiology and Public Health, Brussels, Belgium, ²Ambo University, Department of Public Health, Ambo, Ethiopia

Purpose: Ultra-processed foods (UPFs) dominate modern diets and are associated with poor diet quality and adverse health outcomes. Using recent nationally representative data, this study quantified UPF intake in Belgium and examined variation population subgroup, eating context, food group and overall diet quality.

Methods: Data from 2,789 individuals aged ≥ 3 years participating in the 2022–2023 Belgian National Food Consumption Survey were analyzed. Two non-consecutive 24-hour dietary recalls were collected using GloboDiet®. Foods were classified according to NOVA. UPF intake was expressed as percentage of total daily energy intake. Survey-weighted univariable analyses examined associations with sociodemographic and anthropometric indicators. Contextual patterns were explored by eating occasions and places of consumption and purchase. Associations with total energy intake and diet quality (Diet Quality Index) were estimated using survey-weighted multivariable linear regression.

Results: UPFs contributed 41.2% (95% CI: 40.4–42.0) of total daily energy intake (745 kcal/day). Intake declined with age and was highest among adolescents (52.1%) and individuals with lower educational attainment. Age, education, and region were independently associated with UPF intake, whereas sex and BMI were not. Most UPF-derived energy was consumed at home; although out-of-home meals were more UPF-dense. Higher UPF intake was associated with higher total energy intake (10% increase = +42 kcal/day), lower diet quality (1% increase = –0.16 DQI-I points), and lower fiber intake (10% increase = –0.66 g/day).

Meat and meat substitutes were the largest contributors to UPF energy (19.9%), followed by sugar and confectionery (16.2%), cakes and biscuits (15.0%), dairy products (12.3%), and non-alcoholic drinks (7.0%). Processed meat consumption accounted for nearly all (94.5%) of UPF-derived meat energy.

Conclusion: UPFs contribute substantially to energy intake in Belgium and are associated with higher energy intake and poorer diet quality. Adolescents represent a key-target group. Out-of-home eating and convenience-oriented purchase are key drivers. Major sources include processed meats, confectionery, cakes and biscuits, and sugar-sweetened beverages. These findings support targeted public health strategies such as front-of-pack labeling, taxes on sugar-sweetened beverages, portion guidance for processed meats and warning labels to guide consumers toward healthier choices.

II-P-H.35

Awareness of the Term 'Ultra-processed Food': A Multi-country Study

V. Drolet-Labelle¹, J.R. Jolin^{2,3}, M. Essman^{4,5}, C.M. White⁶, J. Adams⁴, S. Vandevijvere⁷, D. Hammond⁶, L. Vanderlee¹

¹Centre Nutrition, Santé et Société (NUTRISS), Institut sur la Nutrition et les Aliments Fonctionnels (INAF), Université Laval, Québec, Canada, ²Department of Public Health and Primary Care, University of Cambridge, Cambridge, United Kingdom, ³Consortium on Consortium on Law, Science & Health Policy, UC Law San Francisco, University of California, San Francisco, United States, ⁴MRC Epidemiology Unit, University of Cambridge, Cambridge, United Kingdom, ⁵World Food Policy Center, Sanford School of Public Policy, Duke University, Durham, United States, ⁶School of Public Health Sciences, University of Waterloo, Waterloo, Canada, ⁷Scientific Institute of Public Health (Sciensano), Brussels, Belgium

Purpose: The increasing prevalence of ultra-processed foods (UPFs) in food environments, along with rising consumption, is concerning given their association with an increased risk of several non-communicable diseases. Yet little is known about public awareness of UPFs and efforts to reduce their consumption. This study aimed to examine differences in awareness of the term 'ultra-processed food' across countries and sociodemographic groups and to assess whether awareness is associated with efforts to reduce UPF consumption.

Methods: Cross-sectional data from the 2023 International Food Policy Study were analyzed for adults (n=22,762) residing in Australia, Belgium, Canada, Mexico, the United Kingdom (UK), and the United States (US). Participants were asked about their awareness of the term 'ultra-processed food' and their efforts to reduce UPF consumption. Weighted and adjusted logistic regression analyses examined differences across countries and sociodemographic groups and associations between awareness and efforts to reduce consumption.

Results: Participants in Mexico had the highest awareness of the term 'ultra-processed food' (73.7%), followed by those in the UK (65.2%), the US (51.0%), Canada (48.8%), Belgium (46.5%), and Australia (45.1%). Awareness of the term was higher among participants with higher education in all countries, among ethnic majorities in Canada and the UK, and among younger participants in Australia and the US. Efforts to consume less UPF ranged from 51.2% in the US to 64.0% in Mexico and were greater among females and older adults (all countries) and those with higher education (all except in Mexico). Participants who reported being aware of UPF were 2.2 times more likely to make efforts to reduce their UPF consumption (AOR: 2.21, 99% CI: 2.03-2.41, p<0.001).

Conclusion: Differences in UPF awareness between countries may reflect different food environments, media environments and policy approaches to regulating UPF consumption. These results suggest that strategies to increase UPF awareness may lead to modestly greater efforts to reduce intake. To achieve meaningful population-level impact, including across all sociodemographic subgroups, complementary environmental and policy interventions are likely required.

II-P-H.36

Neighbourhood Built-environment Typologies, Physical Activity, and Health-related Fitness by Immigrant Status in Canada

H. Masihay Akbar¹, G.R McCormack², J.J Lang³, S. Prince Ware³, M. Kwan⁴, T.C. Turin⁵, L. Frehlich⁶

¹University of Calgary, Department of Community Health Sciences, Cumming School of Medicine, Calgary, Canada, ²University of Calgary, Department of Community Health Sciences, Calgary, Canada, ³Public Health Agency of Canada, Centre for Surveillance and Applied Research, Health Promotion and Chronic Disease Prevention Branch, Ottawa, Canada, ⁴Brock University, Infant Child and Youth Health Lab, Department of Child and Youth Studies, St. Catharines, Canada, ⁵University of Calgary, Department of Family Medicine, Cumming School of Medicine, Calgary, Canada, ⁶University of Calgary

Purpose: Immigrants are an equity-deserving population whose physical activity (PA) and health often differ from non-immigrants, with differences varying by time since arrival. Few studies, however, have assessed how associations between built environment (BE) and PA and health-related fitness compare by immigrant status. This study explored associations between neighbourhood BE typologies derived using cluster analysis and PA and fitness by immigrant status (Canadian-born, recent immigrants <10 years, established immigrants ≥10 years).

Methods: We conducted a cross-sectional analysis of multiple cycles of the Canadian Health Measures Survey linked to objective measures of walkability (Canadian Active Living Environments [Can-ALE]) and greenness (Normalized Difference Vegetation Index [NDVI]). Accelerometer-measured daily moderate-to-vigorous PA (MVPA) minutes and steps were available for 4674 adults, and VO₂max and grip strength for 3500 adults. Using k-medians clustering of dwelling density, intersection density, points of interest, and greenness, we derived neighbourhood typologies for

H. POLICIES AND ENVIRONMENTS

~820,000 urban postal codes, yielding three types: high-walkability/low-greenness (HW-LG), moderate-walkability/moderate-greenness (MW-MG), and low-walkability/high-greenness (LW-HG). Survey-weighted linear regression models estimated covariate-adjusted associations of neighbourhood type and immigrant status with PA and fitness outcomes, including interaction terms.

Results: Relative to HW-LG neighbourhoods, residents of MW-MG and LW-HG neighbourhoods accumulated 7.2 (95%CI: -11.9, -2.4) and 9.8 (95%CI: -14.8, -4.8) fewer minutes of daily MVPA, with no effect modification by immigrant status. For steps, neighbourhood main effects were null, but immigrant status modified neighbourhood differences: the MW-MG vs HW-LG difference was ~1,960 steps/day larger in recent immigrants than in Canadian-born. Immigrant status also modified neighbourhood-VO₂max associations; among Canadian-born, VO₂max was lower in MW-MG (-1.11 mL·kg⁻¹·min⁻¹, 95%CI: -2.09, -0.14) and LW-HG (-1.72 mL·kg⁻¹·min⁻¹, 95%CI: -2.53, -0.90) relative to HW-LG neighbourhoods, with no associations evident among immigrants.

Conclusion: Walkability and greenness matter for MVPA for everyone, but steps and VO₂max vary by immigrant status, suggesting both population- and place-based strategies may be needed.

II-P-H.37

U.S. Elementary School Recess: State Patterns and Disparities in Access and Withholding

C. Killian¹, E. D'Agostino², B. Kern³, C. Kim⁴, H. Thompson⁵

¹University of New Hampshire, Kinesiology, Durham, United States, ²Duke University School of Medicine, Orthopaedic Surgery, Durham, United States, ³University of Wyoming, Kinesiology and Health, Laramie, United States, ⁴Duke University, Trinity College, Durham, United States, ⁵University of California Berkeley, Community Health Sciences, Berkeley, United States

Purpose: National public health organizations consistently identify daily school recess as a critical contributor to children's physical activity (PA), social and emotional development, and readiness to learn. Despite the recommended 20-minutes of daily scheduled school recess, provision and withholding practices remain inconsistently documented at the state level. This study quantifies daily scheduled daily recess minutes and recess withholding practices in U.S. elementary schools (grades K-6) to understand state-level variation in recess access and implementation.

Methods: The U.S. Physical Education and Physical Activity Policy Data Analysis questionnaire was sent electronically to public elementary physical education (PE) teachers across the 50 U.S. states and District of Columbia (2022-23; 2023-24). Of those who received the survey, 4,294 consented to participate (11.1% response rate), and 3,306 completed the questionnaire (77.0% completion rate). Scheduled daily recess minutes were calculated from PE teacher-reported frequency and duration of distinct recess periods. A composite recess policy score was constructed based on provision of ≥20 minutes of scheduled daily recess and whether recess was withheld (0=< 20-minutes and withholding; 1=<20-minutes, no withholding; 2=≥20 minutes and withholding; 3=≥20-minutes, no withholding). School-level data were aggregated to the state level to calculate mean scores and SDs. Geographic variation was visualized using a state-level gradient map.

Results: Mean daily scheduled recess minutes ranged from 0.0-minutes in Delaware to 27.6-minutes in North Carolina with substantial variability across states. All but seven states (Washington DC, MS, NC, TN, TX, VA, WV) averaged less than 20-minutes per day. The national mean composite recess policy score was 1.22 (SD=1.11). State-level mean scores ranged from 0.00 in Delaware to 2.72 in North Carolina. Geographic variation in mean recess policy scores was observed across the nation, with higher scores in the Southeast and Mid-Atlantic, and lower scores in the Mountain West and Upper Midwest.

Conclusion: Findings demonstrate substantial variability in recess access and withholding practices across U.S. elementary schools. Results reflect implemented practices rather than regulatory policy alone, and highlight the importance of measuring school-level practices directly when characterizing children's access to school-based PA opportunities.

H. POLICIES AND ENVIRONMENTS

II-P-H.38

Factors Associated with Physical Activity in Young People Exposed to Drought Conditions

D. de Melo Lima^{1,2}, D. Bastos Moreno¹, M. Mariana Cardoso Clemente¹, M. Aurélio de Valois Correia Junior¹, R. Jorge Meireles Almendra², M. Virgílio Gomes de Barros¹

¹Universidade de Pernambuco, Recife, Brazil, ²Universidade de Coimbra, Coimbra, Portugal

Purpose: The occurrence of natural disasters, including drought, can impact the practice of Physical Activity (PA) among adolescents, as these events often affect housing conditions, cause economic losses, increase epidemiological risk they tend to change people's lifestyles and the engagement with PA. Therefore, this study aims to identify the factors associated with Moderate-to-Vigorous Physical Activity (MVPA) during leisure time among youth exposed to drought in Pernambuco, a state in the Northeast region of Brazil, affected by drought events between 2020 and 2022.

Methods: A cross-sectional epidemiological study was conducted using secondary data (Digital Atlas of Disasters in Brazil) and primary data (adapted version of the GSHS applied selected public schools (14 to 17 years old). Poisson regression models, with robust variance, were applied to model the PA level, measured through MVPA. A analysis protocol was defined were variables from four dimensions (socioeconomic; school-related; lifestyle/health; and behavioral) were sequentially included in the models.

Results: Data from 1,969 students were analyzed. Being male (OR 1.95; 1.94; 1.78, and 1.27), being employed (OR 1.30; 1.33; 1.28, and 1.14), and regular fruit consumption (OR 1.31 and 1.23) were significantly associated with MVPA in all models in which they were included. The final model identified that enjoying PA and active leisure activities increased the probability of meeting the recommendations (OR 1.77 and 1.39, respectively); however, commuting to school by bicycle or on foot, or demonstrating low interest in being active, was negatively associated with MVPA.

Conclusion: Among adolescents exposed to drought, socioeconomic, behavioral, and personal interest factors increased the probability of meeting MVPA recommendations, while commuting on foot or by bicycle was inversely associated. These findings indicate that interventions to promote MVPA should consider the interaction between sociodemographic, contextual, and behavioral and attitudinal aspects in drought contexts. More consistent evidence will be obtained in future studies with more robust methodological designs and comparisons between different regions and periods.

II-P-H.39

How Did the COVID-19 Pandemic Impact Intakes of Sodium, Saturated Fats, and Free Sugars in Québec, Canada? Preliminary Findings from the NutriQuébec Project

S. Harrison¹, J. Hutchinson¹, K.W. Dodd², C. Laramée¹, A. Lapointe¹, C. Plante³, V. Provencher^{1,4}, N. Carboneau⁵, L. Gauvin^{6,7}, A. Bélanger-Gravel^{1,8}, B. Lamarche^{1,4}, É. Carboneau^{1,4}

¹Centre Nutrition, Santé et Société (NUTRISS), INAF, Université Laval, Quebec, Canada, ²Biometry Research Group, Division of Cancer Prevention, National Cancer Institute, Bethesda, United States, ³Institut National de Santé Publique du Québec (INSPQ), Québec, Canada, ⁴Faculté des Sciences de l'Agriculture et de l'Alimentation, Université Laval, School of Nutrition, Quebec, Canada, ⁵Université du Québec à Trois-Rivières (UQTR), Department of Psychology, Trois-Rivières, Canada, ⁶School of Public Health, Université de Montréal, Montréal, Canada, ⁷CHUM Research Center, Montréal, Canada, ⁸Department of Information and Communication, Université Laval, Québec, Canada

Purpose: The COVID-19 pandemic led to multiple disruptions, resulting in small acute changes in lifestyle habits, including diet. However, longer term changes remain mostly undocumented. The purpose of this study was to examine changes in intakes of sodium, saturated fats (SFA), and free sugars between the pre-pandemic, pandemic, and post-pandemic periods among adults in Québec, Canada.

Methods: Data from the longitudinal NutriQuébec project were used. Periods were defined as pre-pandemic (06-19-2019 to 03-13-2020), pandemic (03-13-2020 to 03-12-2022), and post-pandemic (03-13-2022 to 03-12-2024). Dietary intakes were derived from multiple web-based, 24-hr dietary recalls across periods (n=1 to 12 per respondent in total). The distributions of usual intakes for sodium (mg), SFA (%E), and free sugars (%E) were estimated using the National Cancer Institute's multivariate Markov Chain Monte Carlo method with models stratified by sex. Sex-specific data were combined to observe differences between periods using regression models adjusted for age. Statistical weights were used to ensure population representativeness for age, sex, and region (metropolitan area of census or not).

H. POLICIES AND ENVIRONMENTS

Results: Data from 3327 adults were analyzed. Sodium ($\beta=-60.2$, 95%CI: -375.1, 254.8) and SFA ($\beta=-0.71$, 95%CI: -1.44, 0.02) intakes tended to be lower during the pandemic period compared with the pre-pandemic period, whereas free sugars intakes tended to be higher ($\beta=0.44$, 95%CI: -0.75, 1.63). When comparing the pandemic and post-pandemic periods, sodium intakes tended to further decrease compared with the pandemic period ($\beta=-80.8$, 95%CI: -527.7, 366.0), whereas intakes in SFA ($\beta=0.40$, 95%CI: -0.57, 1.32) and free sugars ($\beta=1.06$, 95%CI: -1.72, 3.83) tended to increase. As such, the trajectory of intakes across periods was constantly and modestly downward for sodium, constantly upward for free sugars, and U-shaped for SFA. None of the observed changes reached statistical significance.

Conclusion: These preliminary findings from the NutriQuébec project revealed no clear change in the intake of nutrients of public health concern from the pre-pandemic to the pandemic and post-pandemic periods in Québec, Canada. Additional analyses are required to replicate and extend these findings.

II-P-H.40

National Policies Targeting Sedentary Behavior in South America

I.K. Alves dos Santos Pinheiro¹, J. Martins², G. De Roia³, A. Cortinez-O’Ryan⁴, A. Ramírez Varela⁵, D. Rodrigues Pereira da Silva¹

¹Federal University of Sergipe, Health Sciences Graduate Program, Aracaju, Brazil, ²University of Lisbon, Faculty of Human Movement, Lisboa, Portugal, ³University of Flores, Laboratorio de Estudios en Actividad Física, Buenos Aires, Argentina, ⁴Universidad de la Frontera, Department of Physical Education, Sports and Recreation, Temuco, Chile, ⁵University of Texas, Health Science Center at Houston, Houston, United States

Purpose: To analyze policy documents specifically focused on reducing sedentary behavior in South America.

Methods: In this qualitative cross-sectional study, we obtained and analyzed the content of national sedentary behavior policies in South America. Searches were conducted on the official websites of the 12 South American countries using the terms „physical activity“ and „sedentary behavior/sedentarism“ in Portuguese, English, and Spanish. This information was supplemented by data from the Physical Activity Policy Inventory of the GoPA!. Eligibility criteria included current national-level documents linked to the health sector and specifically focused on reducing sedentary behavior. The evaluation utilized the Comprehensive Analysis of Policy on Physical Activity (CAPP) tool. Variables included policy type and scope of analysis, the latter encompassing availability and content (target audience and objective). Data extraction and analysis were performed independently by two researchers, with discrepancies resolved by a third reviewer. Finally, the results were analyzed descriptively based on the established categories.

Results: A total of 99 documents were identified, but only 3 met the stipulated eligibility criteria. In Argentina, the documents found were the „National Program to Fight Sedentarism,“ which aims to reduce the prevalence of sedentary behavior in the general population, and the „National Law to Fight Sedentarism,“ which aims to promote health through physical activity. In Brazil, however, the „Guide on the Use of Digital Devices“ was found, which intends to provide evidence-based guidance and recommendations on the healthy and balanced use of digital devices among the young population (children and adolescents). These facts illustrate that although official documents mention sedentary behavior, each addresses the topic in a different way, reflecting a lack of clarity regarding what the term actually means, which ultimately makes it difficult to understand its real impact on daily health.

Conclusion: There is a clear scarcity of policy documents specifically aimed at reducing sedentary behavior within the South American context. Furthermore, a certain confusion remains regarding its definition, which may hinder the understanding of its real impact on health outcomes, as well as the discussion and decision-making process concerning public policy proposals.

II-P-H.41

Social Support for Physical Activity across Population-density Contexts: Associations with Recreational Physical Activity among Portuguese Adults

J. Ribeiro¹, M.J. Almeida²

¹Polytechnic Institute of Bragança/School of Education, Bragança, Portugal, ²University of Porto/Faculty of Sport, CIFI2D, Porto, Portugal

Purpose: Recreational physical activity (RPA) often depends on the social environments in which people live. Social support has consistently been linked with physical activity, but less is known about how different forms of support

H. POLICIES AND ENVIRONMENTS

operate across environments with different population densities. Drawing on a socio-ecological perspective, this study examined associations between several types of social support and RPA among Portuguese adults and explored whether these relationships differed between lower- and higher-density contexts.

Methods: Data were drawn from a cross-sectional survey of Portuguese adults aged 18–64 years ($N = 916$). RPA was assessed using the recreational domain of the Global Physical Activity Questionnaire. Perceived support for physical activity was measured using the Physical Activity Social Support Scale, which captures emotional, informational, validation, companionship, and instrumental support. Population density was used to distinguish lower- and higher-density environments. Analyses included correlations and multiple regression models, including all support dimensions alongside age, sex, socioeconomic status, and population density. Additional interaction models tested whether population density moderated associations between support and RPA. Robust (HC3) standard errors were used throughout.

Results: Participants living in lower-density contexts reported higher levels of RPA than those in higher-density contexts ($M = 7.79$ vs 6.27 ; $p = .05$). All forms of social support were positively related to RPA ($r = .26-.46$), with informational ($r = .46$) and companionship support ($r = .39$) showing the strongest correlations. In adjusted regression models ($R^2 = .257$), informational support ($\beta = .307$, 95% CI [.229, .384]) and companionship support ($\beta = .175$, 95% CI [.089, .262]) remained significantly associated with RPA, while population density showed a small negative association ($\beta = -.096$, 95% CI [-.157, -.034]). Interaction terms between support and density were not statistically significant (all $p > .29$). Stratified models, however, indicated that emotional support was additionally associated with RPA in lower-density contexts ($\beta = .141$, 95% CI [.040, .242]).

Conclusion: Informational and companionship support showed the most consistent associations with recreational physical activity. Although population density did not significantly moderate these relationships, patterns across environments suggest that social support mechanisms may operate somewhat differently across contexts.

I. SOCIO-ECONOMIC INEQUALITIES

I-P-I.01

The Cost and Affordability of Recommended Healthy Diets Compared to Current Dietary Intakes around the World: A Systematic Review and Meta-analysis

C. Mosey¹, E. Porretta¹, D. Richardson¹, V. Saguros¹, R. Vijendran¹, S. Nishi¹, J.J. Lee¹

¹Toronto Metropolitan University, School of Nutrition, Toronto, Canada

Purpose: This study consolidated research from around the world that compared the costs of healthy eating to typical diets to observe and quantify the difference in the cost and affordability of healthy and typical diets.

Methods: Following PRISMA 2020 guidelines, Medline, Web of Science, and Embase were searched for relevant articles published between 01 January 2015 and 22 August 2025. Included studies measured the costs of healthy and current diets within a region. Healthy diets were defined as government-developed food-based or clinical dietary guidelines. Studies were excluded if they compared costs across regions or priced diets for unhealthy individuals. Study characteristics, diet definitions and cost estimation method, household income, food basket contents, and diet cost were extracted from included articles by two independent reviewers. Meta-analyses will include pooling cost and affordability of diets at the country level using inverse-variance weighting, and a random-effects model will account for heterogeneity in the cost and affordability estimates across regions. Subgroup analyses will be performed by country income level as classified by the World Bank and the costing method of diets. Heterogeneity will be assessed using the I² statistic.

Results: Of the 1,760 studies screened, 23 studies from 18 countries met the inclusion criteria. Healthy diets were more expensive than current diets in 9 countries, whereas the opposite was observed in 4 countries, and 5 countries had mixed results or no substantial differences. Healthy diets tended to cost less than current diets in middle-income countries (2 out of 6 countries), while high-income countries showed the opposite trend (healthy diets cost more in 5 out of 9 countries). Diet cost calculations using market prices generally indicated that healthy diets were cheaper, whereas secondary data sources such as national expenditure surveys tended to show healthy diets as more expensive.

Conclusion: Although healthy diets were generally more expensive than current diets, the foods included in “healthy diets” affected the magnitude and direction of the cost differences. The findings underscore the need for regionally-specific economic policies that make nutritious foods more affordable to reduce financial barriers to adhering to healthy diets and promote nutrition equity around the world.

I-P-I.03

Socioeconomic Deprivation Overrides Built Environment: A Bayesian Spatial Analysis of Food Environments, Physical Activity Infrastructure, and Social Context on Chronic Disease Patterns in Mexico City

C. González-Alvarez¹, M. Galeana-Pizaña², C. Medina¹, A. Gallardo-Hernández³, S. Barquera¹

¹National Institute of Public Health, Center for Nutrition and Health Research, Cuernavaca, Mexico, ²Center for Research in Geospatial Information Sciences, Socio-ecological Systems, Mexico City, Mexico, ³Ministry of Health, Home Health Care Division, Mexico City, Mexico

Purpose: To examine how the nutritional healthfulness of formal and informal food environments influences neighborhood-level risks of chronic disease and multimorbidity in Tlalpan, Mexico City; and (2) to assess the extent to which sociodemographic, physical activity infrastructure, and environmental factors mediate these associations across local urban contexts.

Methods: We conducted an ecological study using clinical records from 15,676 adults residing in 177 neighborhoods of Tlalpan, Mexico City. Utilizes multi-source data, including clinical records, official economic directories, satellite imagery, and validated field surveys (Street Food and Beverage Tool). Bayesian spatial models (Besag-York-Mollié 2 specification) were fitted under Poisson and Negative Binomial assumptions, with model selection based on DIC and WAIC. Relative risks (RR) were estimated for individual NCDs and multimorbidity in relation to build food environment indicator: healthy food outlets, unhealthy food outlets, healthy street food, and unhealthy street food, physical and environmental environment indicators: enhanced vegetation index, green areas, the sports and cultural facilities, and private gyms. Finally, socioeconomic environment indicator.

Results: The Poisson model with covariates yielded the best fit. The Social Development Index exhibited a strong,

I. SOCIO-ECONOMIC INEQUALITIES

protective association against all chronic, from 31 to 51% reduced risk. Paradoxically, greater distance to healthy food outlets (RR range: 1.29–1.46) and proximity to private gyms (RR range: 1.24–1.35) were associated with increased disease risk. Spatial analysis revealed that disease and multimorbidity concentrated in the southern, peri-urban, and socioeconomically disadvantaged areas.

Conclusion: Our findings challenge the notion that the mere presence of health-promoting resources such as green areas, recreational spaces, and public sports facilities is a sufficient indicator of the health of the population in segregated cities. Socioeconomic deprivation is the main determinant of spatial inequalities in chronic diseases in Mexico City. Public health interventions should be spatially targeted and focus on both improving food environments and reducing socioeconomic inequalities.

I-P-I.04

Equity-focused Individual Participant Data Meta-analyses of Randomised Controlled Trials: A Review of Current Practices

J. Aagerup^{1,2}, K. E. Hunter², P. J. Godolphin^{1,2,3}, E. Kozuch¹, L. S. Andreas¹, A.L. Seidler^{2,1}

¹University of Rostock, Rostock, Germany, ²University of Sydney, Sydney, Australia, ³University College London, London, United Kingdom

Purpose: Individual Participant Data Meta-Analyses (IPD-MAs) offer opportunities to assess differential intervention effects across socio-demographic groups, enabling more targeted and equitable health recommendations. Yet, to date no guidance exists on how to best use IPD-MA for health-equity related research. This study aims to examine how IPD-MAs with a health equity focus have been conducted, including which equity-related variables they assessed and how they incorporated socio-demographics.

Methods: We conducted a systematic search of medical databases from inception until February 2024 for all IPD-MAs of randomised controlled trials (RCTs). We assessed, which of these have a health-equity focus, defined as examining differences in health outcomes or access to healthcare across socio-demographic groups, as aligned with PROGRESS-Plus. We are extracting their study characteristics, equity-related variables, and methods used to assess equity. Screening and data extraction is conducted in duplicate using Covidence.

Results: We identified 284 IPD-MAs of RCTs. Of those, 40 (14.08%) were classified as having a health equity focus. Early findings suggest studies vary in their focus, including variables such as income, education, race/ethnicity, and geographical location. Data extraction is ongoing; however, initial findings suggest high variability in how equity is defined and assessed along with challenges in harmonising equity-related variables. We identified several IPD-MAs that assessed nutrition, physical activity, or sedentary outcomes in conjunction with health equity.

Preliminary extraction of included studies showed that socio-demographic variables such as income, education, race/ethnicity, and geography were inconsistently defined and harmonised. Subgroup analyses and stratified modelling methods were commonly used for equity related variables.

Conclusion: This study highlights the emerging but inconsistent use of equity-focused approaches in IPD-MAs, including in the fields of diet, nutrition and activity. This underscores the need for standardisation in reporting and analysis across these behavioural domains. Preliminary insights indicate real-world applications in obesity prevention, lifestyle modification, exercise, and device-facilitated activity. Findings will inform methodological guidance to foster more inclusive evidence synthesis and better-targeted public health recommendations and practice.

I-P-I.05

Quadruple Burden of Young Child Malnutrition in the Children's Healthy Living Program, US Affiliated Pacific

R. Novotny¹, R. Dela Cruz¹, K. Hammond¹, A. Yamanaka², P. Coleman³, J. Deenik¹, J. Butel¹, CHL Center of Excellence

¹University of Hawaii at Manoa, Honolulu, United States, ²University of Hawaii Cancer Center, Honolulu, United States,

³Northern Marianas College, Saipan, United States

Purpose: To examine the quadruple burden of malnutrition in children of the US affiliated Pacific (USAP) region.

Methods: 3480 children from the USAP region (Hawai'i, Alaska, Guam, Commonwealth of the Northern Mariana Islands, American Samoa, the Republic of Palau, the Republic of the Marshall Islands, and the Federated States of Micronesia, FSM). Jurisdictions were categorized according to the World Bank income categories of lower middle

I. SOCIO-ECONOMIC INEQUALITIES

income (FSM), upper middle income (American Samoa, Palau, RMI), and high income (Hawai'i, Alaska, Guam, CNMI). Prevalence of population indicators of malnutrition were evaluated – 1) obesity, 2) stunting 3) dietary micronutrient inadequacy, and 4) dietary micronutrient excess. Micronutrients of regional and global importance were examined (vitamin A, vitamin D, vitamin E, niacin, folate, calcium, sodium iron, and zinc). Prevalence of composite (of all studied nutrients) dietary micronutrient inadequacy and excess was also evaluated.

Results: Across the region, there was at least 5% of each type of malnutrition. Mean prevalence of stunting was 6.6%; varying from American Samoa at 1.0% to a high in the Marshall Islands of 26.8%; and of obesity was 13.6%, ranging from a low in the Marshall Islands of 0% to a high in American Samoa of 25.4%. Composite prevalence of (any of the 6 studied) micronutrient inadequacies was 98.1%, driven by dietary Vitamin D inadequacy (96.0%). Composite prevalence of micronutrient excess was 96.2%, driven by sodium excess (92.4%). Among jurisdictions, Kosrae state, FSM, had the highest prevalence of any micronutrient inadequacy at 100%, for Vitamin D. American Samoa had the lowest composite prevalence at 91.6%, again driven by vitamin D. Among all jurisdictions, composite prevalence of micronutrient excess ranged from a low of 77.1% in Chuuk, FSM, to a high in American Samoa of 99%, both mostly driven by excess sodium at 97.8%. Some jurisdictions had a similar prevalence of composite micronutrient inadequacy and excess (eg. Palau, 98.2% and 92%, respectively).

Conclusion: Dietary micronutrient inadequacy and excess are the most prevalent forms of malnutrition. Upper middle-income jurisdictions had the heaviest quadruple burden of malnutrition. Nutrition promotion should focus on healthy diets, especially in regions undergoing a nutrition transition.

I-P-I.06

“The Guilt Just Sits Heavily in my Heart”: Parents’ Experiences of Feeding a Child with Avid Appetite in the Context of Food Insecurity

H. Patel¹, J. Blissett¹, E. Haycraft², S. Newton³, K. Edwards⁴, A. Pickard⁵, C. Farrow¹

¹Aston University, Birmingham, United Kingdom, ²Loughborough University, Loughborough, United Kingdom,

³Birmingham City Council, Birmingham, United Kingdom, ⁴University of Birmingham, Birmingham, United Kingdom,

⁵University of Edinburgh, Edinburgh, United Kingdom

Purpose: The number of families living with food insecurity, the limited or uncertain access to an adequate and stable source of food, has been on a steady rise in the UK. Food insecurity is particularly prevalent in young children with avid appetite profiles, characterised by high food responsiveness, emotional eating and enjoyment of food alongside low satiety responsiveness. Families facing food insecurity often report making difficult choices that lead them to opt for cheaper, energy-dense foods, leaving children in this population more vulnerable to developing obesity or overweight. Furthermore, higher adiposity is associated with both food insecurity and avid appetite. This study aimed to explore caregivers’ experiences of feeding children with avid appetites within food-insecure households, to understand parents’ perceptions of their child’s appetite, how their appetite influences feeding, and to identify the challenges around feeding for these families.

Methods: Ten semi-structured interviews were conducted online with parents of children aged 5-9 years who reported their child had a high interest in food and who were experiencing financial difficulties. Data were analysed using reflexive thematic analysis.

Results: Four core themes were identified. ‘Children’s Avid Appetites: Persistent and Unpredictable’ captures descriptions of children’s heightened and unpredictable appetites. ‘Feeding in the Context of Scarcity: Trade-offs, Control and Survival’ outlines how parents balanced avid appetites with limited resources. ‘Feeding as Emotional Work: Stress, Guilt and Mental Load’ illustrates how the cognitive and emotional labour of feeding is intensified when managing a stronger appetite under scarcity. Finally, ‘Support and Barriers: Making Feeding Easier’ outlines support services parents used to make feeding easier, as well as suggestions for other forms of support that could be helpful for others in their position.

Conclusion: This novel investigation highlights that food insecurity and appetite traits cannot be understood in isolation but that they intersect in ways that shape both children’s eating behaviours and parents’ emotional wellbeing. This information will help tailor interventions targeting parental feeding practices as a method to support healthy child eating behaviour, ensuring a wide reach and avoiding the exacerbation of health inequalities.

I. SOCIO-ECONOMIC INEQUALITIES

I-P-I.07

Barriers and Facilitators of Extracurricular Physical Activity among School-aged Children in Mexico

G. Argumedo¹, M.W. Beets², J. Garcés¹, F. Culp², E. Denova-Gutiérrez³, R. Alvarado⁴, A. Bonvecchio-Arenas⁵, J. Thrasher², A. Jáuregui¹

¹National Institute of Public Health, Physical Activity and Healthy Lifestyles, Morelos, Mexico, ²University of South Carolina, Arnold School of Public Health, South Carolina, United States, ³National Institute of Medical Sciences and Nutrition Salvador Zubiran, Department of Experimental and Rural Studies, Mexico City, Mexico, ⁴National Institute of Public Health, Morelos, Mexico, ⁵National Institute of Public Health, Nutrition Policies and Programs, Morelos, Mexico

Purpose: Limited evidence exists on the opportunities for children in low- and middle-income countries to engage in extracurricular physical activity. This study aims to explore the main perceived barriers and facilitators influencing extracurricular physical activity among school-aged children in Mexico, taking into account the perspectives of children, teachers, head teachers, and parents.

Methods: A multi-method cross-sectional study was conducted, grounded in the qualitative part by a phenomenological approach. It included six focus groups among children aged 9–12 years, six focus groups with parents, ten individual interviews with parents, twelve interviews with teachers, and six with head teachers across Campeche, Morelos, and the State of Mexico, Mexico. Data were analysed using inductive thematic analysis supported by NVivo software, and categorical data were examined through descriptive statistics.

Results: The study findings were organized into three main themes: (1) how children use their time outside school, (2) the places they have access to, and (3) the social environment surrounding out-of-school physical activity. Results indicate that children in Mexico tend to spend their free time engaging in screen-based activities, working, doing household chores, or participating in unstructured physical activity primarily at home, rather than playing sports or being active outdoors. Key facilitators identified included family support, enjoyment of physical activity, availability of programs and facilities, time, living in housing complexes with open common areas, and favorable weather. Nearly 70% engaged in physical activity, however, none of the children reported having been offered extracurricular activities by the school. Fewer than 30% of children participated in extracurricular physical activities within their neighborhoods. More children walked than cycled to and from school. Additionally, those living in urban areas spent approximately three times more time at home compared to children living in coastal areas.

Conclusion: Extracurricular physical activity is not provided by schools for Mexican children; therefore, they rely on their families to participate in structured extracurricular physical activities. The school and neighborhood environments present challenges in providing opportunities for physical activity outside the school day. Policies aimed at promoting children's health and well-being should include school-based extracurricular physical activity programs that support children's health and safety.

I-P-I.08

Community Structures That Facilitate or Hinder Obesity Prevention: A Photovoice Study in Urban and Rural Areas of Low Socioeconomic Status

M. Siwa¹, N. Paduszynska¹, Z. Szczuka¹, E. Kulis¹, J. Kuzminska¹, A. Banik¹, A. Luszczynska¹, T.I.E. Consortium²

¹SWPS University, Psychology, Wrocław, Poland, ²TNO, The Hague, Netherlands

Purpose: Structures within local environments create both opportunities and barriers for healthy living and obesity prevention. Within the *Improve Equity (IM-EQ)* project, we compared how residents and stakeholders in a metropolitan city and a small rural community with low socioeconomic position (SEP) identify, value, and access local environmental features that either support or hinder a physically active lifestyle and healthy diet.

Methods: Two Photovoice studies were conducted using the same protocol. Stakeholders and citizens from the city districts with low-SEP (Wrocław Nadodrze, Wrocław Olbin, Poland; N = 22) and N = 18 participants from low-SEP rural area (Miejska Gorka, Poland) were enrolled. They photographed local structures and provided short narratives specifying location, type, contribution to health, users, access, and need. Descriptive and thematic analyses were used, and district maps visualized spatial distributions.

Results: Across both locations, physical spaces and social connectedness dominated as structures facilitating obesity prevention. In the urban setting, 55 photographs were obtained: 26 physical spaces/landscapes, 19 services/institutions, 6 community groups/associations, 2 cultural/social events, and 2 elements of the local economy. In the

I. SOCIO-ECONOMIC INEQUALITIES

rural setting, 52 photographs were produced: 25 physical spaces/landscapes, 12 community groups/associations, 7 services/institutions, 4 individuals (e.g., local leaders/sports animators), 2 cultural/social events, and 2 economy-related items. Similarities included the high value assigned to public green areas and trusted local leaders as key enablers of community participation. Differences emerged in perceived barriers: urban participants emphasized spatial inequities and access barriers between neighborhoods, while rural participants highlighted reliance on informal support networks, fewer institutional options, and transport limitations. The maps of facilitating structures in both sites revealed clustering near schools, parks, and civic hubs, with “asset deserts” in peripheral areas.

Conclusion: Photovoice was perceived by the stakeholders as supporting reflection on community resources and agency in local planning. The comparison shows shared foundations (green space, social ties) but context-specific barriers (infrastructure gaps in rural areas vs. within-city inequities in urban districts). These insights can inform context-sensitive, equity-oriented strategies for obesity prevention and health promotion across low-SEP communities.

Food Expenditure, Consumption and Sociodemographic Characteristics of Households According to their Affordability of a Healthy Food Basket in Uruguay, a High-income Latin American Country

G. Brunet¹, G. Ares¹, L. Antúnez¹, A. Girona¹, G. Mordecki¹, G. Fajardo¹

¹Universidad de la República, Montevideo, Uruguay

Purpose: Evidence on the relationship between economic disparities in access to healthy foods and food consumption patterns is still scarce. In this context, the present study aimed to analyze households' food expenditure, consumption and sociodemographic characteristics according to their capacity to acquire a Healthy Food Basket (HFB) in Uruguay, a high-income Latin American country.

Methods: The database from the National Survey on Household Expenditure and Income (2016-2017) was used (n=6889). The HFB was constructed based on linear programming for a representative individual of the population, considering their nutritional needs, their food consumption patterns and the recommendations from the national dietary guidelines. It is composed of 69 unprocessed, minimally processed and processed foods and beverages. Households were grouped according to quintiles of income share needed to acquire the basket. For each household group, their monthly per capita expenditure and daily per capita consumption of food groups were estimated, as well as their main sociodemographic characteristics. Welch's ANOVA and Pearson's Chi-square tests were conducted to analyze mean and proportion differences, respectively. A significance level of 5% was used. Analyses were performed using R software.

Results: The income share needed to acquire the HFB (mean=26.5%, median=19.6%) differed among household quintiles ($p<0.05$). Lower capacity to access the basket, i.e., greater income share needed to acquire it, was associated with lower average expenditure on foods and beverages ($p<0.05$), and lower expenditure and consumption of fruits, vegetables, fish, meat, eggs, and ultra-processed foods ($p<0.05$). Despite the average expenditure on cereals being not statistically different among quintiles, their consumption was higher among households with lower affordability of the basket ($p<0.05$). Rates of poverty, unemployment, participation in social protection programs and children or adolescent members were higher among households with lower affordability of the basket ($p<0.05$).

Conclusion: Difficulties in economic access to healthy foods in the country hinder the accomplishment of the right to food and well-being. Households with lower capacity to purchase the basket displayed poorer dietary patterns and greater socioeconomic deprivations, highlighting associations between affordability of healthy foods, socioeconomic inequalities, and health-related behaviors.

Differences in Domain-specific 24-hour Compositional Physical Behaviors across Occupational Groups

N.-P. Hirvonen^{1,2,3}, V. Farrahi^{1,3}, A.-M. Leinonen^{1,2,4}, M. Niemelä^{1,5}

¹University of Oulu, Research Unit of Health Sciences and Technology, Oulu, Finland, ²Oulu Deaconess Institute Foundation sr., Department of Sports and Exercise Medicine, Oulu, Finland, ³TU Dortmund, Institute for Sports and Sport Science, Dortmund, Germany, ⁴Oulu University Hospital and University of Oulu, Medical Research Center Oulu, Oulu, Finland, ⁵University of Oulu, Centre for Wireless Communications, Oulu, Finland

I. SOCIO-ECONOMIC INEQUALITIES

Purpose: Physical behaviors (physical activity, sedentary behavior and sleep) are linked to health and together comprise the 24-hour day. The 24-h physical behavior compositions of working-aged adults might vary due to occupations. Previous research has mainly focused on whole 24-h periods, and less on domain-specific qualities of physical behaviors. We aimed to examine if working-aged adults' compositional 24-h physical behaviors differ among white-and blue-collar groups in work and leisure domains, when occupational skill level is also considered.

Methods: The study population consisted of 2805 adults from the NFBC1966 46-year follow-up study. The participants wore an accelerometer on hip for 14 days. Accelerometry data on waking physical behaviors (light physical activity, moderate-to-vigorous physical activity, and sedentary behaviors) was combined with self-reported diary data on time in bed and work durations. Participants' occupational status was retrieved from national registries in accordance with ISCO-08 and classified into white-and blue-collars and further by occupational skill demands (high vs. low). Means of time spent on physical behaviors during workdays (including working hours and leisure time separately) and non-workdays were calculated for all participants and scaled to 24-h, followed by geometric mean-, log-ratio- and bootstrapped 95% confidence interval calculations for each group. These values were then reported relative to the low-skill blue-collar group to compare the 24-h physical behavior compositions between occupational groups during both workdays and non-workdays.

Results: 24-h physical behaviors differ substantially within occupational groups. The most profound group differences occur during workdays, as high-skill white-collar workers spend the least time in moderate-to-vigorous physical behaviors (log ratio -0.81, 95% CI: -0.86, -0.76) and most time sedentary (log ratio 0.37, 95% CI: 0.33, 0.41) during working hours. During leisure time, high-skill white-collar workers spend the most time in moderate-to-vigorous physical behaviors (log ratio 0.26, 95% CI: 0.18, 0.34). The only significant difference between the groups during non-workdays was observed in high-skill white-collar workers time spent on more moderate-to-vigorous physical behaviors (log ratio 0.15, 95% CI: 0.07, 0.22).

Conclusion: Our findings indicate that 24-h physical behaviors of working-aged adults during workdays are significantly affected by their occupations. Physical activity recommendations for working-aged adults should acknowledge occupational physical demands.

I-P-I.11

Socioeconomic Inequalities in Ever Breastfeeding among U.S. Children Aged 0–6 Years: NHANES 2017–2023

T.N. Folorunso¹, R. Sarbah¹, O.I. Ayoola¹, B.P. Nunes¹, R.M. Tassitano¹, C.M. Tenorio¹, T.R. Flores¹

¹University of Illinois Urbana Champaign, Health and Kinesiology, Champaign, United States

Purpose: Breastfeeding is a key determinant of infant and early childhood health, yet persistent socioeconomic and racial disparities may limit its benefits for vulnerable populations. This study examined the association between socioeconomic status (SES) and ever breastfeeding among U.S. children aged 0–6 years using recent nationally representative data.

Methods: We combined data from the 2017–2020 pre-pandemic and 2021–2023 continuous cycles of the National Health and Nutrition Examination Survey (NHANES). The analytic sample included 2835 children aged 0–6 years with valid breastfeeding and SES data. Ever breastfeeding (yes/no) was assessed. SES was measured using the family poverty-income ratio and categorized as low (<1.3), middle (1.3–3.5), and high (≥3.5). Survey-weighted descriptive statistics and multivariable logistic regression were conducted using the NHANES complex design (strata, PSU, and combined 6-year interview weights). Models adjusted for child age, sex, race/ethnicity, and birth weight.

Results: An estimated 81.3% (95% CI: 78.9;83.7) of U.S. children aged 0–6 years had ever been breastfed, while 18.7% (95% CI: 16.3;21.1) had never been breastfed. Ever breastfeeding increased markedly with SES: 69.6% (95% CI: 65.4;73.8) in low-SES, 81.7% (95% CI: 78.2;85.2) in middle-SES, and 90.0% (95% CI: 87.2;92.8) in high-SES households. In adjusted models, higher SES was strongly associated with breastfeeding; a higher poverty-to-income ratio was associated with 46% higher odds of ever breastfeeding (aOR = 1.46, 95% CI: 1.34;1.59). Older child age was associated with slightly lower odds of ever breastfeeding (aOR = 0.87, 95% CI: 0.78–;.98). Non-Hispanic Black children had significantly lower odds compared with Mexican American and White children, while no significant differences were observed by child sex or birth weight.

Conclusion: Socioeconomic status is a strong predictor of breastfeeding initiation among U.S. children, with substantial gaps between low- and high-income households and race. Persistent socioeconomic and racial inequities highlight the need for targeted, equity-focused breastfeeding support policies and programs to reach low-income and historically marginalized families. Addressing these disparities through culturally responsive and income sensitive interventions is crucial for advancing breastfeeding equity in the U.S.

I. SOCIO-ECONOMIC INEQUALITIES

I-P-I.12

Participatory Health Assets Mapping as the First Step in Equitable Obesity Prevention Policies: Insights from Rural and Urban Municipalities with Low Socioeconomic Position

N. Paduszyńska¹, M. Siwa¹, A. Banik¹, Z. Szczuka¹, E. Kuliś¹, J. Kuźmińska¹, M. Torzewska¹, A. Łuszczynska¹, T. Improve Equity Consortium²

¹SWPS University, Department of Psychology, Wrocław, Poland, ²The Netherlands Organization for Applied Scientific Research (TNO), The Hague, Netherlands

Purpose: This study aimed to develop and pilot-test a protocol for local asset mapping exercise: an engaging, empowering, and context-sensitive participatory process for identifying and quantifying social and environmental health assets that support healthy living in communities with low socioeconomic position (SEP). The process involves stakeholders and citizens investigating together their local community needs. In particular, they researched what the assets are and where they are located, who benefits from these assets, how accessible they are, and how well they respond to local needs.

Methods: A participatory design was applied to develop a protocol and achieve the aims of the study. Two workshops and research-related tasks between the workshops were conducted.

In low-SEP communities in one rural and one urban community. In both locations, residents, healthcare and education specialists and practitioners, and local government representatives were recruited (N = 20 in urban and N= 18 in rural location). Three main activities were implemented:

- World Café (Workshop 1): Participants co-created shared definitions of health-related concepts to build a common understanding of “health” and “well-being.”
- Conscious Community Walk (drift; research activity): Participants identified and recorded health-promoting resources such as people, organizations, institutions, public spaces, cultural activities, and economic elements.
- Collaborative Mapping (Workshop 2): Each identified asset was classified into predefined categories and quantified. Numerical data (counts and frequencies of assets by type and location) were summarized. A geographic map with respective structures was developed and retained in a local community center.

Results: A total of 61 health assets were identified and rated as most important for the local community. In urban location, 20 key assets were mapped, predominantly institutional and service-based structures (e.g., schools, NGOs, sports centers, and cultural centers). In rural location, 41 assets were identified, mainly environmental and social (e.g., green spaces, local leaders, neighborhood networks). Post-workshops evaluations indicated that the process was perceived as inspirational and empowering.

Conclusion: The combination of participatory engagement with quantitative mapping enabled communities to co-produce evidence-based inventories of local resources, and triggered stakeholders’ planning of obesity-related policies. These findings provide a foundation for planning equitable, place-based obesity prevention policies and increase community engagement.

I-P-I.13

Surviving the City: Food and Nutrition Inequalities among Child-headed Households in Korogocho Informal Settlement, Nairobi

A. Ritho¹, D. Osogo², D. Osuka³, C. Kinyua⁴

¹Africa Population and Health Research Centre (APHRC) - ALEP Project - Kenyan (ADVOCACY for CHHs), Nutrition and Food Systems Unit, Nairobi, Kenya, ²Africa Population and Health Research Centre (APHRC), Nutrition and Food Systems Unit, Nairobi, Kenya, ³Africa Population and Health Research Centre (APHRC), Nairobi, Kenya, ⁴Institute of Food Justice and Development (IFJAD), Nairobi, Kenya

Purpose: Child-headed households (CHHs), an emerging yet under-recognized crisis in urban informal settlements across Sub-Saharan Africa, represent one of the most invisible yet vulnerable populations within urban food systems. Defined as households without an adult caregiver and led by the eldest child, CHHs often arise due to orphanhood, parental illness, incarceration, poverty, conflict, or displacement. This study examined the socio-economic determinants of food and nutrition insecurity among CHHs living in Korogocho, an informal settlement in Nairobi, Kenya. It aimed to identify key barriers, coping strategies, and opportunities for strengthening inclusion in urban food systems.

I. SOCIO-ECONOMIC INEQUALITIES

Methods: A qualitative dominant mixed-methods design was employed to explore the lived experiences of food insecurity. A sample of 10 Children Heading Households (aged 10–17) and local stakeholders was engaged. Data collection involved Needs assessment surveys, focus group discussions, and participatory mapping of food access points. The study applied thematic analysis to qualitative data and descriptive statistics to household-level food security and diet diversity indicators. Stakeholder consultations were conducted to validate findings and co-develop potential interventions.

Results: Analysis revealed that 73% of CHHs experienced severe food insecurity, often skipping meals or relying on low-cost street foods. Lack of adult support, high food prices, and competing priorities such as rent and school fees were dominant stressors. Gendered differences emerged in both social risks and survival strategies, with female CHHs facing risks of sexual exploitation, sex-for-food trade and teenage pregnancies, while male CHHs used drugs and joined gangs for food and protection. For survival, female CHHs engaged in caregiving and small-scale vending, while male-headed CHHs undertook casual labor. Despite challenges, participants displayed agency through urban farming, informal food vending, and peer support networks. Exclusion from existing nutrition and social protection programs emerged as a major structural barrier.

Conclusion: CHHs in Nairobi's informal settlements experience multidimensional inequalities that heighten their food insecurity. Addressing their needs requires explicit policy recognition of CHHs as a distinct demographic group and integrating them into social protection programs and urban food systems strategies. Strengthening youth-responsive, nutrition-sensitive interventions can advance equity and build resilience within Kenya's urban food systems and urban poor communities.

I-P-I.14

Barriers to Nutrition Security among Adults with Uncontrolled Type 2 Diabetes: Qualitative Findings from the LINK Trial

K. Garrity¹, J. Garner¹, C.K. Man Hei¹, K. Sonnevile¹, S. Smith², J. Joseph³, D. Walker⁴

¹University of Michigan, Nutritional Sciences, Ann Arbor, United States, ²University of Michigan, Health Management and Policy, Ann Arbor, United States, ³Ohio State University, Division of Endocrinology, Diabetes, and Metabolism, Department of Internal Medicine, Columbus, United States, ⁴Ohio State University, Department of Family and Community Medicine, Columbus, United States

Purpose: Nutrition security is an emerging concept that reflects access to nutritious foods and the conditions that enable health equity. Despite growing attention, limited research explores how individuals with chronic disease experience and navigate barriers to nutrition security in daily life. This qualitative study examined these barriers among adults with uncontrolled Type 2 diabetes (T2D) participating in the LINK trial, a pragmatic, community-based randomized controlled trial addressing food insecurity and diabetes management through layered interventions.

Methods: LINK employs a 2x2 factorial design to evaluate multi-level strategies that address food and nutrition security among adults with T2D at risk of food insecurity in a Midwestern city. All participants receive weekly produce through the Mid-Ohio Farmacy (MOF), a produce prescription program distributing fresh produce via community food pantries. Participants are randomized to one of four arms: (1) MOF only; (2) MOF plus Cooking Matters for Diabetes (CMFD), a six-week culinary and diabetes self-management program; (3) MOF plus Health Impact Ohio (HIO), a community health worker model addressing social needs; or (4) MOF plus both CMFD and HIO. We conducted ~30-minute semi-structured interviews with 25 participants purposively recruited from all four study arms at their 3-month follow-up visit. To support the process of thematic analysis, a codebook was developed based on the two-item Nutrition Security Screener and organized using the domains of the Social Ecological Model, then refined inductively via iterative transcript review and applied consistently across transcripts.

Results: Most participants were female (72%), non-Hispanic Black (76%), and aged ≥50 years. Analysis identified four themes: structural barriers (e.g., non-inclusive food environments), competing constraints (e.g., unstable housing, work demands), individual-level challenges (e.g., health conditions, stress, unmet dietary needs), and barriers to self-efficacy and information gaps (e.g., limited foodwork-related skills, confusion about resources).

Conclusion: Barriers to nutrition security span structural, social, and individual domains that compound among individuals managing chronic disease and unmet social needs. Findings highlight the need for sustained, practical interventions, such as those tested in LINK, that build health-related autonomy, improve self-efficacy, and address competing life demands to promote nutrition security in real-world settings.

I-P-I.15

Process Evaluation of the ProMIO Program: A Culture-sensitive Lifestyle Intervention for Non-western Migrant Older Adults

J. van den Helder^{1,2}, N. van der Spek¹, J. Burger¹, J. Stoop¹, M. Tieland^{1,3}, P.J. Weijs^{1,4}

¹Amsterdam University of Applied Sciences, Faculty of Health, Sport and Physical Activity, Amsterdam, Netherlands, ²VU University, Amsterdam Movement Sciences Research Institute, Amsterdam, Netherlands, ³Deakin University, Institute for Physical Activity and Nutrition, School of Exercise and Nutrition Sciences, Geelong, Victoria, Australia, ⁴Amsterdam University Medical Centers, Vrije Universiteit, Department of Nutrition & Dietetics, Amsterdam, Netherlands

Purpose: As the proportion of older adults continues to rise, the risk of sarcopenia - defined as the progressive loss of muscle mass, strength, and physical function - poses an increasing public health challenge. Lifestyle interventions combining physical activity with adequate dietary protein intake can counteract sarcopenia. Yet, most community-based programs lack cultural sensitivity, limiting their reach among non-Western migrant populations who are particularly vulnerable to functional decline. The ProMIO program was developed as a culture-sensitive lifestyle intervention integrating resistance exercise and dietary counseling, tailored to the cultural and nutritional context of these older adults. While the randomized controlled trial demonstrated improvements in physical performance (Biersteker et al., 2025), this study evaluated the implementation process and explored barriers and facilitators for sustainable adoption of this intervention in practice.

Methods: A mixed-methods process evaluation was conducted among 35 intervention participants (mean age 66±7 years). Twenty-seven participants completed a process questionnaire, and 21 took part in focus groups. An additional focus group was held with professionals, including four dietitians, three physiotherapists, and one trainer. Quantitative data on adherence and satisfaction were analyzed descriptively to assess population reach and engagement. Qualitative data were transcribed and thematically analyzed in MAXQDA, guided by the RE-AIM dimensions: Reach, Effectiveness, Adoption, Implementation, and Maintenance.

Results: Reach was supported by community-based recruitment through trusted local networks, leading to good accessibility and adherence. Participants and professionals perceived the intervention as valuable and motivating. Qualitative findings supported the quantitative results (median [IQR] total intervention score = 8.5 [1.0]). Key facilitators for adoption and implementation included group-based exercise sessions, interprofessional collaboration, personalized feedback, and increased lifestyle awareness among participants. Barriers involved limited integration of culture-specific dietary practices and challenges with home-based exercise adherence due to low motivation. These factors influenced both implementation quality and perceived effectiveness.

Conclusion: ProMIO was well received and supported meaningful lifestyle changes among non-Western migrant older adults. For long-term sustainability, stronger cultural adaptation and enhanced support for home-based exercise are recommended to improve the efficacy and scalability of this intervention in community settings.

I-P-I.16

Integrating Prenatal Care with Food Provision and Education Impacts Food Insecurity, Even in Communities with High Deprivation

L. Bailey Davis^{1,2}, K. Herb Neff^{1,2}, GC. Wood², K. Brandt³, K.A Marshall⁴, AD. Mackeen⁵, L. Wright², S. Lutcher^{2,1}, C.J. Seiler^{2,1}, A.R Chang⁶

¹Geisinger College of Health Sciences, Population Health Sciences, Danville, United States, ²Geisinger College of Health Sciences, Center for Women's and Children's Research, Danville, United States, ³Family Health Council of Central Pennsylvania, Camp Hill, United States, ⁴Geisinger College of Health Sciences, Emergency Medicine, Danville, United States, ⁵Geisinger College of Health Sciences, Maternal-Fetal Medicine, Danville, United States, ⁶Geisinger College of Health Sciences, Department of Population Health Sciences, Danville, United States

Purpose: Food insecurity and high community-level deprivation are mutually reinforcing challenges that contribute risk to adverse perinatal outcomes. We examine whether integrating prenatal care with a community food provision program and/or telehealth nutrition education protects against food insecurity.

Methods: A randomized controlled trial at Geisinger Health (Pennsylvania, USA) in 2024 enrolled pregnant patients with household income <185% federal poverty level. Participants were randomly assigned to models: Clinic (usual prenatal care); Clinic-WIC (referral to the Special Supplemental Nutrition Program for Women, Infants and Children); Clinic-RDN (referral to Registered Dietitian/Nutritionist); Clinic-WIC-RDN. Self-reported household food security (USDA

I. SOCIO-ECONOMIC INEQUALITIES

6-item) was assessed by study questionnaire. Changes in food insecurity (low/very low food security) from baseline to 6-month follow-up and across models were compared using GEE regression. This model was adapted to evaluate association of change in food security with area deprivation index (ADI, Neighborhood Atlas). Trial Registration: NCT06311799.

Results: Among 240 participants, the mean (Standard Deviation [SD]) age was 29.2 (6.1) years, 65% were white, 14% black, and 12% Hispanic. Participants enrolled at 17+6 weeks gestation and most lived in communities with high/very high ADI. Food insecurity prevalence was similar at baseline: Clinic model 59%; Clinic-WIC model 40%; Clinic-RDN model 55%; Clinic-WIC-RDN model 44%. At 6-month follow-up, participants experienced significant decreases in food insecurity, but there were no statistically significant differences between models. The absolute difference in food insecurity from baseline to 6-month follow-up in the Clinic model was -14.6% ($p=0.029$); Clinic-WIC model was -4.2%; Clinic-RDN model was -19% ($p=0.016$); Clinic-WIC-RDN model was -15.9% ($p=0.0049$). Among participants in communities with very high deprivation (decile 9-10), food insecurity decreased by 21% ($p=0.031$), from 51% at baseline to 30% at follow-up whereas small decreases (47% to 41%) were observed among those areas with less deprivation (deciles 0-8).

Conclusion: Prenatal care, usual or enhanced with a nutrition expert via telehealth, emerged as promising models to reduce food insecurity. The impact of food provision on food insecurity was inconsistent, potentially explained by adherence. Women living in communities where adverse social exposomes present risk experienced reduced food insecurity. Further research is needed with larger sample sizes and adequate statistical power to confirm findings.

I-P-I.17

Social and Physical Environmental Correlates of Movement Behaviors, Body Weight Status, and Well-being among Adolescents in Nigeria: A YoPA Project Narrative Review

D.R. Omotoso¹, A.B. Ogunleye², A.C. Okafor³, N. Kollipara⁴, M.J.M. ChinAPaw⁵, A.L. Oyeyemi^{6,3}

¹Redeemer's University, Department of Human Anatomy, Ede, Nigeria, ²Value Re-Orientation for Community Enhancement, Gender and Education, Osogbo, Nigeria, ³Redeemer's University, Department of Physiotherapy, Ede, Nigeria, ⁴Arizona State University, Barrett Honors College, Tempe, United States, ⁵Amsterdam UMC, Department of Public and Occupational Health, Amsterdam, Netherlands, ⁶Arizona State University, College of Health Solutions, Phoenix, United States

Purpose: Nigeria is experiencing rapid urbanization and a chronic disease epidemiological transition, with adolescents increasingly affected by physical inactivity, sedentary behavior, overweight and obesity, as well as mental health challenges. While evidence supports the importance of social and physical environmental factors in improving adolescents' health, understanding these issues among Nigerian adolescents remains limited. This narrative review aims to synthesize findings from available literature on social and physical environment correlates of movement behaviors, body weight status, and well-being among adolescents in Nigeria.

Methods: We searched electronic databases for original research articles, published prior to January 2025, on socioenvironmental factors and movement behaviors and health among Nigerian adolescents (aged 10-20 years). Each study underwent screening and data extraction by two reviewers. Study quality was assessed with the modified Downs and Black checklist, and data were analyzed using narrative synthesis.

Results: A total of 25 articles met the inclusion criteria, all of which were cross-sectional studies. The review suggests that social class, school settings, peer relationships, family structure, electronic device use in the bedroom, neighborhood walkability features, availability of open recreational spaces, and urbanization are important socioenvironmental factors related to multiple movement behaviors and health outcomes among Nigerian adolescents. Some of these relationships were modified by gender and socioeconomic status.

Conclusion: The evidence highlights the need for context-specific interventions and more longitudinally designed research that incorporates socioenvironmental factors to promote healthier lifestyle movement behaviors, and enhance health and overall well-being among Nigerian adolescents.

I. SOCIO-ECONOMIC INEQUALITIES

I-P-I.18

Intersection of Gender and Socio-economic Status and Engagement in Physical Activity among Adolescents Living in European Union Member Countries

R. Araujo¹, R. Espirito Santo¹, G. Melo¹, C. Agostinis-Sobrinho¹

¹Klaipeda University, Faculty of Health Sciences, Klaipeda, Lithuania

Purpose: To identify the associations of the intersection of gender and socio-economic status (SES) with no or low moderate to vigorous-intensity physical activity (MVPA).

Methods: We used cross-sectional data from the 2018 Health Behaviour in School-aged Children (HBSC). HBSC is a World Health Organisation collaborative cross-national study that uses a self-reported questionnaire to collect data on adolescent health and well-being. Gender, SES, and no or low MVPA were self-reported. SES information was collected using the Family Affluence Scale III. The threshold of ≤ 1 day/week of 60 min/day of MVPA was used to categorise those with no or low MVPA. Weighted relative frequencies were calculated using the 'survey' package. The 'svyglm' function, from the 'survey' package, was used to fit Poisson regression models accounting for sample weights. The 'InteractionR' package was used to calculate interactions. All analyses were conducted using R Studio Software.

Results: We analysed data from 25 out of 27 European Union member countries. The final sample was composed of 117,496 adolescents (50.9% girls, average age of 13.5), and 11.7% of the participants reported no or low MVPA. Boys with medium and low SES presented a probability of no or low MVPA 48% and 114% higher than boys with high SES, respectively [Boys with medium SES, PR: 1.48 (1.37;1.59); Boys with low SES, PR: 2.14 (1.97;2.33)]. The probability of no or low MVPA was, respectively, 35%, 91%, and 186% higher for girls with high, medium, and low SES than the probability observed for boys with high SES [Girls with high SES, PR: 1.35 (1.23;1.47); Girls with medium SES, PR: 1.91 (1.78;2.06); Girls with low SES, PR: 2.86 (2.65;3.08)]. Additive interaction analyses revealed that the PR observed for being a girl with low SES was greater than the sum of the estimates of being a girl and having low SES alone [RERI: 0.36 (0.19;0.53)]. Country-level inequalities were also observed.

Conclusion: Physical activity, even considering its minimal uptake, is a behaviour unequally distributed across different intersections of gender and SES among European adolescents. Girls from low socioeconomic backgrounds should be the priority in strategies for promoting physical activity.

I-P-I.19

Demographic and Socioeconomic Factors Associated with Food Insecurity in Urban Alaska Families

J. Galbreath¹, J. Butel¹, A. Yamanaka¹, Y. Shvetsov¹, K. Braun¹, L. Shallcross², R. Novotny¹

¹University of Hawaii at Manoa, Honolulu, United States, ²University of Alaska Fairbanks, Fairbanks, United States

Purpose: Examine demographic and socioeconomic characteristics associated with food security status among households with young children in urban Alaska. The identified correlates of food insecurity provide locally-relevant insight for public health, policy, and food assistance efforts in the communities where most Alaskans reside.

Methods: Secondary cross-sectional analysis used data from Fairbanks, Matanuska-Susitna Valley, Kenai Peninsula, and Anchorage collected by the Children's Healthy Living (CHL) program. Household-level food security status was assessed by dichotomizing participant responses to a single-item question about running out of money for food before the end of the month, adapted from a U.S. Department of Agriculture survey. Food security status was examined by household characteristics using chi-square tests ($p < 0.05$). Adjusted stepwise (entry/retainment $\alpha = 0.05$) and logistic regression models were performed to select household characteristics and determine factors associated with food insecurity, accounting for shared variance and community clusters.

Results: Among 1,527 households, 31% were food insecure. Food security status differed by 14 household characteristics: child ethnicity, race; caregiver education, unemployment status; and household size, living arrangement, multigenerational living, income, and six food assistance variables. Among food insecure households, 80.6% used food assistance vs. 44.3% of food secure households. A higher proportion of food insecure households used Supplemental Nutrition Assistance Program (SNAP) (51.3% vs. 19.6%), Special Supplemental Nutrition Program for Women, Infants, & Children (WIC) (53.2% vs. 33.6%), food banks/pantries (36.5% vs. 10.7%), and free/reduced-cost school meals (32.5% vs. 14.2%). In an adjusted model, SNAP (aOR 1.70, 95% CI 1.32-2.20) and food bank/pantry use (aOR 2.65, 95% CI 1.44-4.88) were associated with food insecurity, as were Hispanic children (aOR 1.73, 95%

I. SOCIO-ECONOMIC INEQUALITIES

CI 1.21-2.46), medium (aOR 1.40, 95% CI 1.23-1.58) and large households (aOR 2.09, 95% CI 1.05-4.18), cohabiting couples (aOR 1.46, 95% CI 1.34-1.59) and single caregivers (aOR 1.71, 95% CI 1.12-2.62), high school level education (aOR 1.74, 95% CI 1.3- 2.19), and household income <\$35,000 (aOR 2.02, 95% CI 1.75-2.34), compared to reference categories.

Conclusion: Both SNAP and food bank/pantry participation were prevalent among food insecure households, yet food insecurity persisted. Food assistance and socioeconomic inequities should be considered in prevention, reduction, and alleviation of food insecurity among urban Alaska populations.

I-P-I.20

Sociodemographic Disparities and Weight History among U.S. Adults in the International Weight Control Registry

A.M. Gorczyca¹, R.D. Sayer², J.G. Clina¹, S.K. Das³, A.E. Caldwell⁴, J.E. Friedman⁵, T.K. Chui², S.B. Roberts⁶, J.O. Hill⁵, G. Wagner

¹University of Kansas Medical Center, Internal Medicine, Kansas City, United States, ²University of Alabama at Birmingham, Department of Family and Community Medicine, Birmingham, United States, ³Tufts University, Jean Mayer USDA Human Nutrition Center on Aging, Boston, United States, ⁴University of Colorado School of Medicine, Medicine-Endocrinology/Metabolism/Diabetes, Aurora, United States, ⁵University of Alabama at Birmingham, Department of Nutrition Sciences, Birmingham, United States, ⁶Dartmouth College, Geisel School of Medicine, Hanover, United States

Purpose: The purpose of this study was to examine sociodemographic disparities in weight history profiles among U.S. adults enrolled in an online study and evaluate longitudinal associations between weight history and sociodemographic characteristics using mixed effects modeling.

Methods: This analysis used baseline data collected from December 2020 to October 2021 using the International Weight Control Registry (IWCR). Participants self-reported sociodemographic characteristics, self-categorized a weight history group (Successful, Regain, Attempted) and provided current weight/height, highest adult weight/date, lowest adult weight/date, and weight at age 18. Group differences were evaluated using Dwass-Steel-Critchlow-Fligner tests for continuous variables and Chi-square tests for categorical variables ($\alpha=0.01$). Linear mixed models were fit with repeated measures of BMI, including weight history condition, time, and their interaction as fixed effects. Models adjusted for age (linear and quadratic), race, sex, household income, marital status, geographic region, social vulnerability index, and rurality. An unstructured covariance matrix modeled within-subject correlation.

Results: Among 1,619 U.S. IWCR participants, 504 (32.5%) reported Success, 964 (59.5%) Regain, and 151 (9.3%) Attempted weight loss. Those reporting Success were more often male, married, higher income, and non-Hispanic White ($p<0.01$). Participants reporting Attempted were more likely to be non-Hispanic Black, unmarried, and receiving government assistance ($p<0.01$). Mixed effects modeling demonstrated significant effects of time, weight history condition, and a condition $\times$ time interaction (all $p<0.0001$), indicating distinct BMI trajectories across weight-history groups. Relative to reference levels, BMI was higher among participants identifying as non-Hispanic Black participants (2.82 kg/m²), female (1.68 kg/m²), lower income (1.30 kg/m²), and unmarried (1.16 kg/m²), and lower among residents of the Northeast (-1.98 kg/m²). A significant nonlinear relationship was observed between BMI and age; BMI was higher in middle-aged adults and lower in older adults.

Conclusion: Distinct sociodemographic patterns characterize weight history groups while BMI trajectories vary significantly across these groups in the IWCR. These findings underscore the need for increased representation of marginalized populations and tailored equity-focused weight management interventions.

I-P-I.21

Feasibility and Cultural Adaptation of Nutrition Education for Rural Latino Communities: The ¡HOLA! Health & Nutrition Program

G. Harrison¹, N. Lugo Muñoz¹, A.M. Palacios^{2,1}

¹GROW Initiative GA, Savannah, United States, ²Giann Ping Hsu College of Public Health, Georgia Southern University, Savannah, United States

Purpose: The purpose of this study was to evaluate the feasibility, cultural relevance, and implementation of the ¡HOLA! Health & Nutrition program. The program aimed to increase health and nutrition literacy among marginalized

I. SOCIO-ECONOMIC INEQUALITIES

Latino/Hispanic families in rural Coastal Georgia. The program curriculum was evidence-based and implemented through a combination of community engagement strategies, partnerships, health promotion across multiple channels, and direct and indirect nutrition and health education activities.

Methods: This study utilized a mixed-method, convergent, and participatory design through a “Developmental Evaluation” which helped prioritize real-time programmatic modifications to address changing community needs, barriers, and disability-specific needs of the population served. Formative evaluation included four bilingual focus groups (n = 72) to identify community-specific barriers and facilitators. Process evaluation tracked reach, fidelity, delivery locations, and dosage across 34 sessions at various community sites (clinics, churches, libraries) measured via post-class surveys (n = 83). Qualitative data from facilitator notes and open-ended responses were analyzed via thematic analysis, while quantitative data were analyzed with descriptive statistics.

Results: Formative findings identified critical barriers, including language and low education barriers, and the fear of immigration enforcement. In response, 100% of materials were transitioned to bilingual, plain-language visual formats, and intervention delivery was modified to use as many channels as possible, both in-person and online, and the addition of services. Process measures showed consistent engagement at health clinics but fluctuating attendance at community sites due to safety concerns related to increased immigration enforcement activities. The program acceptability was high, with 91.7% of participants reporting overall satisfaction. Qualitative themes observed that the inclusion of culturally familiar ingredients and texture-modification strategies for caregivers of individuals living with disabilities were the most valued components.

Conclusion: The behavioral nutrition HOLA! The program is acceptable among marginalized immigrant and Latino populations; the flexibility provided by the Developmental Evaluation processes enabled rapid changes that addressed important barriers faced during program implementation. This research provides a scalable framework for implementing highly acceptable nutrition and health literacy programs in „high-fear“ or resource-limited environments, through cultural and disability-friendly adaptations, linguistic access, trusted community partnerships, and flexibility and creativity in implementation.

I-P-I.22

Identification of Sedentary or Insufficiently Active Profiles in Belgium

E. Grimm¹, N. Berger¹, V. Versele², F. Pandolfi¹

¹Sciensano, Brussels, Belgium, ²VUB, Brussels, Belgium

Purpose: The Belgian national surveys (Food Consumption Survey and Health Interview Survey), which measure physical activity in the Belgian population, showed that part of the adult population failed to achieve the WHO guidelines for physical activity. Importantly, physical activity level remained largely stable over the last decade. Therefore, identifying different profiles is critical for policymakers, as it enables the targeting of high-risk groups and the development of evidence-based, context-specific interventions.

Methods: The data from 2025 Health Interview Survey were analyzed using a Factor Analysis of Mixed Data (FAMD) and a Hierarchical Clustering on Principal Components (HCPC) model. The variables included in these analyses cover several complementary dimensions: physical activity, sedentary behavior, sociodemographic characteristics and health status.

Results: Five clusters were identified. Clusters 1 and 2 reflect high-risk profiles marked by overweight or obesity, multimorbidity, low physical activity, and prolonged sedentary time. Cluster 1 mainly includes urban women aged 55–74, while Cluster 2 consists mostly of men living in suburban or rural areas with limited screen time. Cluster 3 comprises young rural women with normal BMI and at least one chronic condition, low transport-related activity, and low sedentary time. Clusters 4 and 5 include individuals without chronic disease: older urban men (overweight, active, low sedentary time) and young suburban men (normal BMI, active, high sedentary time), respectively.

Conclusion: This analysis enabled the identification of sedentary or insufficiently active profiles. Although no definitive recommendations can be made, preliminary proposals were developed and will need to be validated through further analyses and/or field-based studies.

I. SOCIO-ECONOMIC INEQUALITIES

I-P-I.23

Association of Neighborhood Deprivation with Body Mass Index and Accelerometry-measured Physical Activity in Berlin: Data from the German National Cohort (NAKO)

L. Krist¹, K. Wolf², M. Schulze^{3,4}, T. Pischon^{5,6}, F. Herbolzheimer⁷, K. Steindorf⁸, T. Keil^{1,9,10}

¹Charité-Universitätsmedizin Berlin, Institute of Social Medicine, Epidemiology and Health Economics, Berlin, Germany, ²Helmholtz Zentrum München GmbH, German Research Center for Environmental Health, Institute of Epidemiology, München, Germany, ³German Institute of Human Nutrition Potsdam-Rehbruecke, Department of Molecular Epidemiology, Potsdam, Germany, ⁴University of Potsdam, Institute of Nutritional Science, Potsdam, Germany, ⁵Charité - Universitätsmedizin Berlin, Berlin, Germany, ⁶Max-Delbrueck-Center for Molecular Medicine in the Helmholtz Association (MDC), Molecular Epidemiology Research Group, Berlin, Germany, ⁷German Cancer Research Center, Division of Physical Activity, Cancer Prevention and Survivorship, Heidelberg, Germany, ⁸German Cancer Research Center (DKFZ), Division of Physical Activity, Cancer Prevention and Survivorship, Heidelberg, Germany, ⁹University of Würzburg, Institute of Clinical Epidemiology and Biometry, Würzburg, Germany, ¹⁰Bavarian Health and Food Safety Authority, Institute for Health Resort Medicine and Health Promotion, Bad Kissingen, Germany

Purpose: Neighborhood socioeconomic status (nSES) is associated with health status and physical activity, but data on this association are scarce for urban environments in Germany. We aimed to examine how physical activity (PA) and body mass index (BMI) vary across Berlin neighborhoods while taking individual risk factors into account.

Methods: We analyzed baseline data from the Berlin study centers of the German National Cohort (NAKO). nSES was assigned using Berlin's Social Index from the Social Structure Atlas (1=most advantaged, 7=most disadvantaged) based on residential prognosis areas and divided into three categories (1–2=best, 3–5=middle, 6–7=worst nSES). Outcomes were accelerometer-measured moderate-to-vigorous PA (MVPA) (minutes/day) and BMI (kg/m²), calculated from measured height and weight. We used descriptive analyses and maps to visualize spatial patterns of nSES, PA, and BMI across Berlin. Multivariable linear regression models were fitted for PA and BMI, adjusting for sociodemographic and lifestyle covariates. Results are presented as regression coefficient β with 95% confidence intervals (CI).

Results: Of 31,075 Berlin NAKO participants, 11,922 with complete accelerometry data were included (mean age 50.6±12.9 years; 52.8% women). Mean MVPA was 69.8±34.2 min/day and mean BMI was 25.8±4.7 kg/m². Across the seven nSES categories, PA was relatively similar overall, whereas BMI increased consistently with worsening nSES. The spatial distribution maps supported these patterns. In the three-category analysis, participants residing in the most disadvantaged neighborhoods (nSES 6–7) had significantly lower PA than those in the most advantaged areas (1–2) (adjusted β -2.18 min/day, 95%CI: (-4.03;-0.32), while the middle group (3–5) did not differ. For BMI, the most disadvantaged group had higher values (adjusted β +0.85 kg/m² (0.60;1.10), also with little difference for the middle group compared to the best nSES group.

Conclusion: In Berlin, PA and BMI differences by neighborhood may be driven less by a linear nSES gradient but rather by differences in the most disadvantaged areas. This threshold-like pattern may be important for targeting urban health promotion and prevention strategies.

II-P-I.02

Interaction and Hierarchical Structure of Socioeconomic Status and Other Social Categories in Swedish Adolescents' Physical Activity during School Time

M. Haji¹, S. Lundvall¹, A. Fröberg¹, B. Algurén¹

¹University of Gothenburg, Department of Food and Nutrition and Sport Science, Gothenburg, Sweden

Purpose: Currently, most research on inequalities in socioeconomic status (SES) has studied SES in isolation. Little attention has been paid to how SES interacts with other social categories, as well as to adolescents' voices and perspectives. Therefore, this study aims to explore how Swedish adolescents conceptualise SES alongside other social categories and how these categories are perceived to interact during school-based physical activity (PA).

Methods: This qualitative multiple-case study examined two municipally operated schools in western Sweden. The schools included an advantaged school (with Swedish background and high SES) and a disadvantaged school (with foreign backgrounds and low SES). Data were gathered in spring 2024 through semi-structured focus group interviews with adolescents in grades five, seven, and nine. In addition to SES, the social categories discussed included gender,

I. SOCIO-ECONOMIC INEQUALITIES

ethnic culture, age, and religion. Data were analysed using reflexive thematic analysis with an abductive approach.

Results: Three key themes emerged: a) social categorical meetings, b) student interaction, and c) school as a setting. The first theme emphasised the heterogeneity within SES, which was further nuanced by other social categories. Additionally, SES was considered to carry less weight and be less connected with gender and age. The second theme highlighted the existence of hegemonic power within PA during school time, where SES was regarded as irrelevant, as hegemonic power often related to social categories in which students were heterogeneous. The concluding theme centred on contextual factors, where SES was seen to manifest differently within and outside the school environment. Specifically, SES was believed to have no impact on PA during school but did influence PA outside of school.

Conclusion: Understanding whether SES (and other social categories) within schools is homogeneous or heterogeneous can help clarify how SES influences PA during school time and, consequently, support efforts to reduce inequalities and promote equality. Additionally, the homogeneous or heterogeneous nature of SES may reveal the presence or absence of hegemonic power, which, when heterogeneous, might lead to exclusion, segregation, and teasing. Furthermore, contextual and domain-specific factors can aid in understanding and explaining the structural factors underlying (in)equalities in SES across various domains and contexts.

II-P-I.04

Prevalence and Trends of Physical Activity, Sedentary Behaviors, and Sleep in Adolescents and their Association with Sociodemographic Factors

C. Medina¹, A. Jáuregui², I. Campos³, S. Barquera⁴

¹National Institute of Public Health, Physical Activity and Healthy Lifestyles, Mexico City, Mexico, ²National Institute of Public Health, Physical Activity and Healthy Lifestyles, Cuernavaca, Mexico, ³National Institute of Public Health, Mexico City, Mexico, ⁴National Institute of Public Health, Cuernavaca, Mexico

Purpose: To examine the prevalence and trends in physical activity, sedentary behavior, and sleep in Mexican adolescents, and their association with sociodemographic factors.

Methods: A cross-sectional study with data from adolescents aged 15–19 years from the ENSANUT (National Health and Nutrition Survey) from 2012 to 2022–2024. Generalized linear models were used to compare daily minutes and prevalence by survey and sociodemographic factors, and logistic regression was used to analyze associations with sociodemographic factors.

Results: Women, individuals under 18 years old, and those who do not work, as well as those with higher well-being and living in urban areas, reported fewer minutes per day of moderate-to-vigorous physical activity. Daily sitting time increased from 2012 to 2022–2024 in almost all groups. Noncompliance with the three behavior recommendations increased from 2012 to 2022–2024. Women, adolescents under 17, those who do not work, with high well-being and education levels, living in urban areas and in the north of the country, were more likely to fail to meet one or all three recommendations.

Conclusion: These findings highlight the need to design strategies that specifically address the sociodemographic characteristics associated with lower compliance with the recommendations

II-P-I.05

Meeting Physical Activity Guidelines among Rural, United States Youth Across Household Income, Sex, Sports Participation, and Age Subgroups: 2022-2023 National Survey of Children's Health

A. Johnson¹, M.J Von Seggern², A.E Rogers², K. Wilson³, K. Davis⁴, C. Beattie⁵, MR. Umstattd Meyer⁶, R. Carson⁷

¹San Diego State University, School of Exercise and Nutritional Sciences, San Diego, United States, ²University of Nebraska Medical Center, Omaha, United States, ³Arizona State University, Tempe, United States, ⁴University of South Carolina Upstate, Valley Falls, United States, ⁵Texas A&M AgriLife Institute, College Station, United States, ⁶Baylor University, Waco, United States, ⁷Community Impact Collaborative, Windsor, United States

Purpose: This study aimed to examine the prevalence of meeting physical activity (PA) guidelines among sociodemographic subgroups defined by household income, sex, sports participation, and age among rural-dwelling youth in the United States (US).

Methods: This cross-sectional study used the combined 2022-2023 National Survey of Children's Health, focusing on

I. SOCIO-ECONOMIC INEQUALITIES

youth aged 6-17 living outside a metropolitan statistical area (i.e., rural). Survey-weighted proportions of meeting PA guidelines (past week PA of 60+ minutes/day) were estimated across sociodemographic groups defined by income (0-199% FPL [federal poverty level], $\geq 200\%$ FPL), sex (male, female), and sports participation (sport, non-sport) to develop eight subgroups (e.g., High-income Male Sport, High-income Male Non-sport, etc.). To visualize disparities, equity plots were generated with High-income Male Sport serving as the reference group. Subgroups were also 1) examined separately by age (6-11 and 12-17 years) and 2) compared by age (6-11 versus 12-17 years). Adjusted Wald tests were conducted for pairwise comparisons.

Results: The final analytic sample included 10,809 youth ($M_{age} = 11.7$ years; 51.6% male). Overall, 25.6% of youth met guidelines. The prevalence of meeting guidelines ranged from 6.2% (95% CI: 3.9%–9.6%) among High-income Female Non-sport (ages 12-17) to 43.3% (34.9%–52.1%) among Low-income Female Non-sport (ages 6-11). When comparing all subgroups to the High-income Male Sport group, significant disparities were seen in the overall sample and within both age groups. For ages 12-17, five subgroups showed significantly lower PA prevalence than the reference, including High-income Non-sport (Male and Female), High-income Female Sport, and Low-income Female Non-sport (all $p < 0.05$). When comparing by ages 6-11 versus 12-17, significant differences were observed in all subgroups except the Low-income Sport (Male and Female).

Conclusion: This study found that most rural US youth do not meet PA guidelines, with the lowest prevalence observed among adolescents (12-17 years), females, and non-sport participants. Critically, sports participation appears to serve as an „equalizer“, as its involvement mitigated the age-related PA decline seen in all other subgroups and lower disparities between income levels. These findings necessitate targeted interventions that promote both organized sports for all youth and increased unstructured PA to effectively address the significant disparities in PA, particularly among adolescent females.

II-P-I.06

Is Food Insecurity a Weight Problem? Cross-sectional Associations between Dietary Patterns and Food Insecurity in Adolescents from an Amazon Region, Brazil

P. Dias dos Santos Barbosa¹, A. Peloggia de Castro¹, A.C. Barco Leme²

¹Centro Universitário São Camilo, Nutrition, São Paulo, Brazil, ²University of São Paulo, Nutrition, São Paulo, Brazil

Purpose: The geographic area of a country may play an important role on aspects of food insecurity. Understanding associations of socio-demographic factors with diet quality among adolescents living in an urban-remote area of Brazil, close to the Amazon region, can inform behavioural-change strategies and public health policies for advancing nutrition and health disparities. This paper aims to verify associations between household food insecurity and overall diet quality.

Methods: Full-time high-school students ($n=337$, $M_{age} = 16.22$; 95%CI 16.10-16.33years; 63.50% female) completed a self-report survey on a food screener, socio-demographic and weight/height measurements. The most knowledgeable member of the household ≥ 18 yo completed the 14-item Brazilian Food Insecurity Scale. The 19-item food screener was used to evaluate overall dietary quality of the adolescents based on recommended dietary guidelines with scoring points ranging from 0 to 65. Socio-demographic and anthropometric measurement were used as potential co-variables. Descriptive statistics and regression models were calculated for the associations considering $p < 0.05$ as significant.

Results: Approximately, 65% of the adolescents' experience food insecurity and 25.47% were overweight. Adolescents showed significant differences in total diet quality scores with slightly lower diet quality score for adolescents living in marginal ($M_{score} = 24.20$) and severe ($M_{score} = 23.46$) vs. secure ($M_{score} = 26.06$) households ($p < 0.01$). Adjusted models showed that adolescents in the 3rd tercile of diet quality (highest) had 11% of chances for food insecurity (OR = 0.89; 95%CI 0.82, 0.85; $p < 0.01$). The scores for fruits and vegetables ($\beta = -0.14$; 95%CI -0.25, -0.03; $p < 0.02$) and foods high in fat and sodium ($\beta = -0.05$; 95%CI -0.09, -0.01, $p = 0.04$) were significantly negatively associated with food insecurity.

Conclusion: Adolescents diet quality worsen as increase severity for food insecurity. Dietitians and other nutrition/food practitioners can use results to advocate for and plan behavioural-change strategies to improve adolescent health and nutrition.

I. SOCIO-ECONOMIC INEQUALITIES

II-P-I.07

Socioeconomically Disadvantaged Children's Screen Time Behaviors by Weight Status

P. Son¹, Y. Nie¹, Q. Tan¹, P. Yang¹, P. Murray², A. Staiano², F. Wang³, S. Gordon^{2,4}, S. Chen¹

¹Louisiana State University, School of Kinesiology, Baton Rouge, United States, ²Pennington Biomedical Research Center, Baton Rouge, United States, ³Louisiana State University, Department of Geography & Anthropology, Baton Rouge, United States, ⁴Louisiana Healthcare Connections, Baton Rouge, United States

Purpose: Excessive screen time is associated with childhood obesity. The purpose of the survey study was to comprehensively examine the relationship between screen time and weight status in a socioeconomically disadvantaged population using a recently validated instrument.

Methods: 739 parent proxies of children aged 5-11 years mostly enrolled in Medicaid (83.9%) in a United States (US) southern state responded to an online questionnaire called the *Movement Behavior Questionnaire - Child* (MBQ-C; open version). Eight items of the MBQ-C separately measured passive (e.g., watch TV, videos, movies) and interactive (e.g., play games, look at photos, video chat) screen time on weekdays and weekend days. The survey also gathered parent-reported child weight and height, along with their sociodemographic characteristics. Weight and height were used to calculate body mass index (BMI) and BMI percentile scores. Two weight status groups were defined for analysis, namely, overweight or obese (OWOB): $\geq 85^{\text{th}}$ BMI percentile vs normal weight: $< 85^{\text{th}}$ BMI percentile.

Results: Only 24.9% of the sample met the ≤ 2 h/day sedentary screen time guideline. Compared to normal weight children ($M = 294.5 \pm 7.2$ min/day), OWOB children ($M = 364.3 \pm 10.6$ min/day) reported greater amount of total screen time ($\Delta M = 69.8$ min/day, 95% CI = 45.0-94.6, $p < 0.001$). OWOB children also had 41% lower odds of adherence to screen-time guideline (OR = 0.59, 95% CI = 0.39-0.86, $p = 0.008$). The difference of screen time between weight-status groups was most pronounced in passive screen time, particularly on weekdays ($\Delta M = 63.2$ min/day, 95% CI = 47.6-78.7, $p < 0.001$). Race, age, sex, and household income did not significantly moderate the relationship between screen time and weight status.

Conclusion: Over 75% of the socioeconomically disadvantaged children failed to meet the screen time guidelines. Being OWOB further puts these children at elevated risk for excessive screen time. These findings suggest the need for tailored interventions to not only curb overall screen time but also mitigate specific types and timings of screen time behaviors (i.e., passive screen use on weekdays) for OWOB children from socioeconomically disadvantaged background child population.

II-P-I.08

Association between Parental Social Position and Childhood Overweight: Mediation by Parental Feeding Practices and Lifestyles during Early Childhood

M. Baietto¹, C. Le Gal¹, A. Descarpentrie², M. Lecorguillé¹, L. Pavicic¹, L. Vanhoutte¹, J. Pilato³, J. van der Waerde³, M.-A. Charles¹, B. Heude¹, S. Lioret¹

¹Université Paris Cité and Université Sorbonne Paris Nord, Inserm, INRAE, Centre for Research in Epidemiology and Statistics (CRESS), Paris, France, ²Department of Pediatrics, The Saban Research Institute, Children's Hospital Los Angeles, University of Southern California, Los Angeles, United States, ³Social Epidemiology Mental Health and Addictions (ESSMA), Institut Pierre Louis d'Epidémiologie et de Santé Publique (IPLESP), Sorbonne Université, INSERM, Paris, France

Purpose: In high-income countries, children of parents with a low socioeconomic position (SEP) or a migration background are disproportionately affected by overweight from preschool age, yet the causal mechanisms remain poorly understood. These associations are likely partly driven by interrelated postnatal factors, particularly parental feeding practices (breastfeeding and age at complementary feeding) and energy balance-related behaviors (EBRBs). This study aimed to assess the extent to which parental feeding practices and early-life EBRB patterns (lifestyle patterns, LPs) mediate social inequalities in childhood overweight at age five.

Methods: The analysis included 5-year-old children from the French ELFE birth cohort ($n=8,388$). Parental social characteristics—migration status and SEP (education level and household income)—were collected through questionnaires, and anthropometric data were obtained from the child's health booklet. We used counterfactual mediation analysis to assess the potential mediating role of previously identified children's LPs—namely, “Early complementary feeding along with discretionary consumption and high screen time at age 2” (unhealthy), “Balanced diet and leisure activities other than screens at age 2” (healthy), and “Optimal feeding practices and poor sleep at age

I. SOCIO-ECONOMIC INEQUALITIES

2" (mixed)—in the associations between the different dimensions of social position and childhood overweight (IOTF definition). Models accounted for potential intermediate confounders, including parental BMI and lifestyle, cesarean delivery, and birth weight, where appropriate.

Results: Children born to immigrant parents or to parents with lower SEP had higher scores on the unhealthy pattern. This LP explained 10.7% of the association between parental migration status and childhood overweight, 18.4% of the association with parental education, and 24% of the association with household income. Children born to immigrants or to parents with lower income also had higher scores on the mixed pattern, which explained 9.8% of the association between parental migration status and childhood overweight and 10.5% of the association with household income.

Conclusion: These findings (1) suggest that feeding practices and early-life EBRBs jointly contribute to shaping social inequalities in childhood overweight from early life and (2) highlight potential targets for early multibehavioral interventions to reduce these inequalities.

II-P-I.09

Heart Health for All: A Community-based No-cost Cardiac Rehabilitation Pilot in Rural Northern Ontario

K.H. Karvinen¹, P. Oh², J. Tuomi³

¹Nipissing University, School of Physical and Health Education, North Bay, Canada, ²University Health Network, Cardiovascular Prevention and Rehabilitation Program, Toronto, Canada, ³North Bay Cardiology, North Bay, Canada

Purpose: Cardiac rehabilitation programs are a cornerstone of supportive care for people who have experienced a cardiovascular event. Disparities in access to cardiac rehabilitation, however, have been well documented with people of lower socioeconomic status having less opportunity for participation. To compound this, rural and northern areas in Canada have substantially fewer publicly funded cardiac rehabilitation programs available, further reducing access to people of lower income. To mitigate this, a partnership of stakeholders recently launched a novel, no-cost cardiac rehabilitation program in a northern and rural town in Ontario, Canada. A pilot group of cardiac patients completed a 16-week cardiac rehabilitation program in summer/fall 2025. Participants were prescribed 5 weekly exercise sessions including a once weekly supervised session, weekly education sessions, and nutrition counselling. Participants from the pilot group were invited to participate in a focus group upon completion of the program in order to explore the unique context of a novel no-cost cardiac rehab program in a rural and northern setting.

Methods: Participants (N=10) completed a questionnaire and participated focus groups. Focus groups were asked a series of open ended questions that gave insights on the program in terms of (a) access/barriers, (b) expectations/motivation, (c) experience with the program, (d) outcomes/impact, (e) any context-specific factors (i.e., Northern and small town/rural context), (f) sustainability/continuity, and (g) improvements/feedback. Data were audio-recorded, transcribed, and analyzed using thematic analysis.

Results: Three primary themes emerged from the data: praise for the program effectiveness, gratitude for access to a no-cost program, and challenges due to long distances for travel. Participants overwhelmingly reported that they found improvement in their physical health and well-being and found the program to be enjoyable. Participants frequently noted gratitude for access to the program as they could not have afforded a cardiac rehab program at a private facility. Driving long distances to access the program was a recurring point.

Conclusion: This pilot demonstrates that a no-cost cardiac rehabilitation model can improve health and well-being while reducing inequities in access for rural and lower-income populations. Future directions include implementation of a virtual program to mitigate long commutes within the catchment area.

II-P-I.10

Patterns of Food Insecurity and Weight Change among Rural Adults in a Diabetes Prevention Program

G. Wagner¹, C. Kracht¹, A. Gorczyca¹

¹University of Kansas Medical Center, Internal Medicine, Kansas City, United States

Purpose: The purpose of this study was to examine the prevalence of food insecurity among rural-living adults over the first six months of a diabetes prevention program and the association of food insecurity patterns with weight change.

I. SOCIO-ECONOMIC INEQUALITIES

Methods: This secondary data analysis included 24 U.S. rural-living adults with a body mass index ≥ 25.0 kg/m² and at risk for type 2 diabetes. All individuals enrolled in a 12-month community-based diabetes prevention program with goals of 5-7% weight loss and 150 minutes per week of physical activity. At baseline and 6-months food security in the past 30 days was assessed using the USDA Household Food Security Scale. Participants were categorized as food secure (FS, score: 0-1) or food insecure (FI, score: ≥ 2). Linear regression models examined main and interactive effects of FI status and time (baseline and 6 months) on 6-month weight change (kg), adjusting for gender and baseline weight.

Results: Participants were predominantly female (87.5%), weighed 102.5 ± 21.0 kg at baseline, FI was prevalent at baseline (29.1%) and 6-months (25%); over 40% ($n=10$) of participants experienced FI at any time point, and 12.5% transitioned from FS to FI. There were no differences in 6-month weight change ($n=24$, -2.0 ± 4.6 kg) in participants who were FI at baseline ($n=7$, -1.8 ± 5.8 kg) compared to those who were FS at baseline ($n=17$, -2.3 ± 4.1 kg; $p=0.895$). Participants who were FS at 6 months lost more weight ($n=16$, -3.6 ± 4.3 kg) than those who were FI at 6 months ($n=8$, $+1.2 \pm 3.5$ kg; $p=0.0127$). Participants who transitioned from FI to FS ($n=2$, -9.8 ± 0.7 kg) lost more weight than those who remained FI ($n=5$, $+1.4 \pm 2.6$ kg; $p=0.0086$) and those who became FI at 6 months ($n=3$, $+0.8 \pm 5.4$ kg; $p=0.0244$) but not those who were always FS ($n=14$, -2.7 ± 3.8 kg; $p=0.0842$).

Conclusion: In this sample of rural-living U.S. adults, experiencing FI during a diabetes prevention program was associated with unfavorable weight loss outcomes. Replication in larger samples would expand upon these results with the potential to improve the effectiveness of diabetes prevention programs in rural areas.

II-P-I.11

Emerging Evidence on How U.S. Pay-what-You-can Restaurants Improve Diet Quality among Food-insecure Individuals

A. MacMillan Uribe¹, L. Borchers², H. Eicher-Miller³, R. Nayga⁴, A. McNeely⁵, R. Seguin-Fowler⁶, J. Szeszulski¹, X. Wang⁷

¹Texas A&M AgriLife Research, Institute for Advancing Health Through Agriculture, Dallas, United States, ²Texas Christian University, Fort Worth, United States, ³Purdue University, West Lafayette, United States, ⁴Texas A&M University, College Station, United States, ⁵University of Texas-Dallas, Richardson, United States, ⁶Texas A&M University, Institute for Advancing Health Through Agriculture, College Station, United States, ⁷Texas A&M AgriLife Research, Fort Worth, United States

Purpose: Food insecurity leads to poor diet quality and increased chronic disease risk. U.S. community cafes (hereafter cafes) are pay-what-you-can restaurants that offer nutrient-dense meals and welcome individuals of all income levels. Cafes may improve diet quality among food-insecure individuals, but evidence remains limited. We aimed to summarize our research team's emerging findings to advance understanding of how this novel café model may improve diet quality.

Methods: We summarized findings from four studies conducted by our research team on how cafes may influence diet quality. Two qualitative interview studies with executive directors and managers (EDMs) ($n=13$) and guests ($n=39$) explored how cafes address healthy food access. One national cross-sectional survey of guests ($n=74$) characterized guests' perceptions of café meals. One observational assessment of diet quality of café meals selected by food-insecure guests ($n=40$) compared to meals they consume elsewhere. Diet quality was determined using Healthy Eating Index (HEI) (scored 0-100, with higher scores indicating stronger alignment with Dietary Guidelines for Americans).

Results: Four cross-cutting themes emerged. (1) **Improving diet quality:** Survey data indicated 61% of food-insecure respondents reported healthier diets due to café meals. The observational study supported these perceptions: Average HEI score for café meals was 12.3 points higher than for meals consumed elsewhere (46.7 ± 10.5 vs. 34.4 ± 11.6 ; $p < 0.0001$). (2) **Increasing healthy meal access:** Across interviews, EDMs and guests described cafes as providing reliable access to nutrient-dense meals. Guests reported reduced hunger and eating more balanced meals at cafes than through other charitable food programs. (3) **Promoting dignity through guest agency:** EDMs and guests valued guests' ability to select meals freely, versus having limited choices at other charitable food programs. This autonomy, combined with welcoming atmosphere, was viewed as central to promoting dignity. (4) **Cafe utilization barriers:** Guests noted some barriers, such as long wait times and limited hours.

Conclusion: Preliminary evidence consistently indicates cafes' potential to improve diet quality among food-insecure guests by improving access to a variety of nutritious meals in a dignified way. Findings underscore the need for future research to quantify how using cafes affects diet quality over time and strategies for overcoming guest barriers.

Examining Perceived Food Environment, Social Cohesion, and Food Security among Older Asian Americans in the San Francisco Bay Area

S. Chen¹, T. Le¹, M. Kraatz¹, L. Vollmer², J. Bergman¹

¹San Jose State University, Nutrition, Food Science, and Packaging, San Jose, United States, ²University of California Cooperative Extension, Half Moon Bay, United States

Purpose: Older Asian American adults represent one of the fastest-growing populations in the United States (U.S.). This study examined the associations between perceived food environment, social cohesion, demographics, by food security level among older Asian American adults living in the San Francisco Bay Area in California, United States. A secondary aim was to assess the internal consistency of a social cohesion scale within this population.

Methods: A 32-item cross-sectional survey was administered from April to July 2025. Participants were recruited from senior nutrition programs to complete a Qualtrics survey. Eligible participants self-identified as Asian American, lived in the San Francisco Bay Area for at least one year, and were older than 65 years. The survey was available in English, Chinese, Korean, and Vietnamese and contained validated measures from the 6-item U.S. Household Food Security Survey Module, the Nutritional Environment Measures Survey - Perceived, and a social cohesion scale. Descriptive statistics, Mann-Whitney U test, Chi-square tests, and Cronbach's alpha were applied for quantitative analysis.

Results: Of the 203 participants, 77 (38%) were food insecure. Food security status differed by ethnicity ($p<0.002$); Chinese and Vietnamese respondents had higher rates of food insecurity (42% and 44%, respectively). Significant differences were observed between foreign-born and U.S.-born participants ($p=0.007$) and across income groups ($p<0.001$). Food-secure participants perceived higher availability of healthy food at the stores they shop at compared to food-insecure participants ($p<0.001$). The social cohesion scale showed low internal consistency (Cronbach's $\alpha=0.480$), and it did not differ between food security status ($p=0.142$).

Conclusion: Although participants were recruited from congregate meal sites, the prevalence of food insecurity remained higher than the national average. Differences in perceived healthy food availability suggest variation in shopping behaviors between groups. The low reliability of the social cohesion scale suggests that it may fail to capture culturally relevant aspects of connectedness in Asian cultures, where relationships center on family rather than friends or community members. These findings highlight the need for culturally tailored approaches to addressing food insecurity and social connectedness among older Asian American adults.

II-P-I.14

Co-creating Healthy Food Interventions with Adolescents to Promote Health Equity: Insights from a Participatory, System-based Approach

L.R. Delfmann¹, M. Vos², C. Lachat¹

¹Ghent University, Department of Food Technology, Safety, and Health, Faculty of Bioscience Engineering, Ghent, Belgium, ²Ghent University, Department of Marketing, Innovation and Organisation, Faculty of Economics and Business Administration, Ghent, Belgium

Purpose: Social inequalities shape adolescents' access to and choices around healthy food. Those growing up in socially vulnerable circumstances face disproportionate barriers and are at greater risk of unhealthy diets. Addressing these inequities requires system-level change. Participatory, system-based approaches that engage adolescents as co-creators may be key to developing contextually grounded and sustainable solutions. This study aims to: (1) explore how adolescents in a socially vulnerable school context perceive their food environment and food choices; (2) identify actions they propose to improve this environment; and (3) examine their experiences of a co-creation process to design a school-based healthy food intervention.

Methods: An ongoing qualitative observational study is evaluating a co-creation process involving 15 students, one teacher, a facilitator, and a group of adult stakeholders (e.g., school staff, local health and food actors) who provide input and support to the adolescent co-creators. Participants review and extend a causal loop diagram (CLD) previously developed by another group of adolescents from the same school, mapping feedback loops influencing healthy eating and identifying leverage points for change. CLD analysis focuses on the version validated with participants, examining feedback loops and leverage points to characterise perceived system drivers and dynamics. Building on these insights, participants will collaboratively develop and prioritize intervention ideas. The co-creation process will be evaluated through focus groups and interviews guided by the PROSECO framework, exploring

I. SOCIO-ECONOMIC INEQUALITIES

domains such as delivery, participation, experience, context, and perceived impact (e.g., ownership, empowerment, capacity building). Data will be analyzed using framework analysis in MaxQDA, combining deductive coding guided by PROSECO domains with inductive identification of emergent themes.

Results: Data collection is ongoing. Preliminary findings indicate key influences on adolescents' food choices include exposure to food-related social media, peer dynamics, family support, and limited availability of healthy options at school. Adolescents report feeling heard and valued through co-creation, though sustaining engagement across sessions is challenging.

Conclusion: Engaging adolescents from socially vulnerable contexts as co-creators, supported by adult stakeholders, can reveal the lived complexities of food environments and possibly foster more equitable, contextually relevant, and empowering intervention design.

II-P-I.15

Development of a Preliminary Nutrition Security Screening Tool that Incorporates Measures of Health Equity

E. Serrano¹, R. Liebe², H. Davis¹, C. Holmes¹, S. Misyak¹

¹Virginia Tech, Blacksburg, United States, ²Oklahoma State University, Stillwater, United States

Purpose: Current measures of nutrition security do not assess health equity, a key construct in the USDA's 2021 nutrition security definition and indicator of social cohesion. Shame and stigma, established systemic barriers that disadvantage populations and preclude people at the individual level from accessing food resources, are health equity indicators that can be added to a nutrition security measure. Current nutrition security measures assess only food security and diet quality but not the interrelated health equity construct, potentially underestimating nutrition insecurity levels. The purpose of this study was to develop a nutrition security screening tool that incorporates health equity indicators.

Methods: A preliminary Nutrition Security Screening Tool was developed using survey data from 898 caregivers of young children with an income of 100% of the federal poverty level. The survey included the Hunger Vital Signs as strong predictors of food security, measures of shame, stigma, and diet quality. Stepwise linear regression with 5-fold cross-validation was used to identify a subset of these items predictive of raw food security scores while balancing model simplicity and correlation with other key nutrition security concepts. Non-significant items were removed.

Results: The final six items include two Hunger Vital Signs questions, one diet quality item (vegetable intake), two shame items, and one experienced stigma item. The model demonstrated strong predictive performance against the USDA Household Food Security Survey Module (18-item; Spearman $\rho=0.78$, $R^2=0.6$) and acceptable internal consistency (Cronbach's $\alpha=0.6$), especially given the multidimensionality and brevity. Convergent validity was supported by correlations with food security, diet quality, anxiety, depression, and physical health.

Conclusion: This preliminary tool includes measures of each nutrition security constructs: food security, diet quality, and health equity. Stigma and shame, which undermine social cohesion, are important health equity indicators. This tool can be used to monitor population nutrition security and evaluate interventions and programs designed to address to promote nutrition security status. Additional validation is needed for populations other than caregivers of young children.

II-P-I.16

Socioeconomic Differences in Ultra-processed Food Purchases in New Zealand

G. Lopes da Cruz^{1,2}, M.L. da Costa Louzada^{1,2}, K. Garton³, B. Swinburn³, T. Gontijo de Castro⁴, S. Mackay³, K. Bradbury³

¹University of São Paulo, Department of Nutrition, São Paulo, Brazil, ²University of São Paulo, Center for Epidemiological Research in Nutrition and Health, São Paulo, Brazil, ³University of Auckland, Department of Epidemiology and Biostatistics, Auckland, New Zealand, ⁴University of Auckland, Department of Nutrition, Auckland, New Zealand

Purpose: This study provided the first national estimate of ultra-processed food (UPF) purchases among New Zealand households and examined their associations with socioeconomic characteristics, addressing a critical gap in evidence on dietary inequalities in New Zealand.

Methods: This cross-sectional study used data from the 2019 New Zealand Nielsen Homescan® panel (October 2018–October 2019), nationally representative by household demographics and geography. A sample of 1,800 households with consistent participation was included. Detailed records of all foods and beverages purchased for

I. SOCIO-ECONOMIC INEQUALITIES

household consumption and sociodemographic characteristics (household income, sex and age of the primary shopper, household life stage and size) were analysed. Foods were classified using the Nova system to identify UPF and linked to national food composition databases to estimate energy content. The relative share (%) of UPF in total energy available from household purchases was calculated (mean $\pm$ standard deviation). Linear regression assessed associations between household socioeconomic characteristics and UPF share, with statistical significance at $P \leq 0.05$.

Results: UPF represented $56.8 \pm 13.5\%$ of total available energy from household food purchases in New Zealand. UPF showed the greatest variation across income quintiles, with a decreasing contribution to total energy as household income increased (-5.4 percentage-point [pp] difference across extreme quintiles), p -trend < 0.001). No significant variation was observed by sex. Differences by age were observed in pairwise comparisons, with higher energy availability from UPF among those aged >65 years compared with those aged <35 years ($+3.2$ pp), no linear trend. By household life stage, mixed ($+3.3$ pp) and older ($+2.8$ pp) family households had higher availability compared with young families. Single-person households had the highest contribution of energy from UPF compared with households with two (-3.6 pp) or three (-3.4 pp) members, with no linear trend.

Conclusion: UPF represented over half of the energy from New Zealand household food purchases across all income groups, with a higher proportion among lower-income households and modest variation across other sociodemographic characteristics. These findings indicate widespread national consumption and support the need for comprehensive population-level policies to reduce UPF contribution to the diet, including marketing regulation, fiscal policies and measures to promote minimally processed foods.

II-P-I.18

Using Physical Activity for Reintegrating Individuals into the Workforce: An Exploratory Study in the Swiss Disability Insurance System

I. Abdelli¹, P. Gelius¹

¹UNIL / ISSUL, Lausanne, Switzerland

Purpose: Disability Insurance (DI) is a compulsory Social Insurance (SI) in Switzerland, aimed primarily at rehabilitating individuals with disabilities linked to chronic health conditions. Physical Activity (PA) is known to positively affect health by mobilising and developing individuals' preserved capacities, thereby supporting their reintegration into society. Despite this potential, PA promotion largely occurs within the health sector, and its role within SI remains underexplored. This exploratory case study examined the feasibility of implementing a PA intervention for DI beneficiaries in French-speaking Switzerland.

Methods: Data were collected through qualitative semi-structured interviews (60–90 min) with officials from the cantonal DI offices of Fribourg, Geneva and Vaud. The interview guide focused on participants' trajectories, beneficiary profiles, existing interventions, and the legal and practical possibilities for introducing PA programs. Attention was paid to interviewees' conceptions, practices and attitudes regarding PA. After transcription, a qualitative discourse analysis was conducted based on central categories drawn from the DI Act (RS 831.20).

Results: Findings indicate that the Swiss legal framework governing DI provides sufficient flexibility to integrate PA as a socio-professional reintegration measure. Respondents highlighted a strong alignment between DI objectives and individually tailored PA promotion. They emphasised that PA interventions may be particularly appropriate during the first year of support and for young adults, who often require more comprehensive measures. However, participants also stressed that broader adoption of PA within DI depends on addressing professionals' attitudes and strengthening their awareness of the complementary nature of DI goals and PA promotion.

Conclusion: According to social security data, socio-professional PA interventions within DI could potentially reach more than 200,000 beneficiaries. PA is especially relevant for vulnerable populations at higher risk of developing multimorbidities, which can be partially or fully prevented through regular activity. Ensuring long-term access to low-cost PA measures, therefore, requires that key actors within the social welfare system recognise the shared interests of SI and PA promotion and support their integration into DI practice.

Intersectional Sampling in Physical Activity and Health Research: A Scoping Review Revealing High-income Country Concentration and a Framework for Operationalization

U.S. Dankoly¹, G. Segantin², Z. Tieges³, P. Dall⁴, S. Chastin⁵

¹Glasgow Caledonian University, Glasgow, United Kingdom, ²Vrije Universiteit Amsterdam, 2. Department of Public and Occupational Health, Amsterdam Public Health Research Institute, Amsterdam UMC, Amsterdam, Netherlands, ³Glasgow Caledonian University, Department of Computer Science, Glasgow, United Kingdom, ⁴Glasgow Caledonian University, Department of Physiotherapy, 1. School of Health and Life Science, Glasgow, United Kingdom, ⁵Glasgow Caledonian University, Department of Physiotherapy, School of Health and Life Science, Glasgow, United Kingdom

Purpose: Physical activity and health research is often biased missing the distinct health burdens experiences by Individuals at the intersection of multiple axes of social disadvantage (e.g. Gender, Age, SES, geography) . Analytical advances enable estimation of intersectional effects, yet this is only possible for samples representative of the intersectionality in a population. No framework guides how samples should be designed to capture intersectional populations. We mapped how intersectionality has been conceptualised and operationalized at the sampling stage in physical activity and health research.

Methods: We conducted a scoping review following Joanna Briggs Institute guidance and PRISMA-ScR reporting standards (OSF: 10.17605/OSF.IO/W7BY4). We searched seven databases from inception to 8 December 2024 (updated Feb 2026). Studies were eligible if sampling was explicitly designed around combinations of power axes or if methodological papers discussed sampling in relation to intersectionality. Two reviewers independently screened records, extracted data, and classified intersectional depth.

Results: From 51 154 records, ten studies met inclusion criteria. All originated from high-income Anglophone settings; none were conducted in low- or middle-income countries. Only three studies implemented intersectional sampling with primary data collection. No probability-based design governed intersections as sampling units. Implemented designs operationalized at most three axes. We developed the Intersectional Sampling Triad (structural, processual, relational dimensions) and a four-category Taxonomy through inductive-deductive synthesis. Five mechanisms constrain intersectional sampling to high-income contexts: infrastructure dependency, missing identity variables, digital access filters, language restrictions, and cell sparsity.

Conclusion: Intersectional sampling remains more rhetorical than operational. The Intersectional Sampling Triad and Taxonomy provide tools for distinguishing designs embedding intersectionality in sampling governance from those invoking it as post-hoc framing. Realising intersectionality's promise for health equity requires investment in empirical implementation and structural change supporting LMIC-led methods development.

II-P-I.20

Cardiovascular Disease Risk Factors among Staff of Two Universities in South-Eastern Nigeria

F.C. Gideon-Iheme¹, D. Samuel², G.O. Iheme^{3,2}

¹Abia State University Teaching Hospital, Department of Medicine & Surgery, Aba, Nigeria, ²Michael Okpara University of Agriculture Umudike, Department of Human Nutrition & Dietetics, Umuahia, Nigeria, ³Uppsala University, Food Studies, Nutrition & Dietetics, Uppsala, Nigeria

Purpose: Cardiovascular diseases, the leading cause of death globally, are largely influenced by poor lifestyle habits developed over time. Academic work environments are often characterised by sedentary behaviour and long working hours, which may contribute to adverse lifestyle factors. Therefore, this study aims to assess the risk factors for cardiovascular diseases among university Staff at Michael Okpara University of Agriculture, Umudike, Nigeria.

Methods: This descriptive cross-sectional study employed a multi-stage sampling technique to select 440 academic and administrative staff from two Nigerian Universities: Michael Okpara University of Agriculture, Umudike, and Abia State University, Uturu, Nigeria. Ethical approval (FMC/QEH/G.596/Vol. 10/544) was obtained, and written informed consent was secured from all participants. Data were collected on respondents' family history, dietary practices, and patterns of alcohol and tobacco use. Standardised procedures were used to obtain anthropometric measurements, physical activity and blood pressure indices. Descriptive statistics were used to summarise the study variables, while inferential analyses, such as the chi-square test and correlation analysis, were applied to examine associations

I. SOCIO-ECONOMIC INEQUALITIES

between cardiovascular disease risk factors. All statistical analyses were conducted using IBM SPSS Statistics, Version 27.

Results: Family history of diabetes mellitus (21.1%) and hypertension (52.7%) was reported by most of the study participants. Poor lifestyle habits characterised by unhealthy snacking, infrequent fruit and vegetable consumption, alcohol intake and meal skipping were reported. The majority (>60%) of the respondents had low (less than 600 MET) physical activity levels and were classified as overweight or obese based on BMI. However, waist-to-hip ratio assessments indicated a lower risk of obesity-related non-communicable diseases. Only a tenth of the study participants had normal blood pressure levels, with elevated or hypertensive status observed among respondents. Dietary practices, physical activity, and lifestyle habits were found to be significantly ($p > 0.05$) associated with anthropometric and blood pressure indices.

Conclusion: The observed poor lifestyle practices among university staff are associated with adverse health outcomes that predispose individuals to cardiovascular diseases. There is a clear need to create supportive work environments that promote overall health and well-being.

I-P-J.01

Multilevel Within-person Associations between Sleep and Physical Activity in Young Adults: An Ambulatory Assessment

R. Filo¹, L. Knapová¹, S. Elavsky¹

¹University of Ostrava, Department of Human Movement Studies, Ostrava, Czech Republic

Purpose: Observational evidence on sleep–physical activity associations is inconsistent (e.g., Atoui et al., 2021), likely reflecting heterogeneity in samples, monitoring duration, measurement approaches, and analytic levels. Most prior studies relied on brief monitoring periods, with few examining within-person day-to-day or mid-term dynamics. This study investigated these associations between sleep and next-day steps across four 14-day bursts over one year in a large sample of young adults. We hypothesized that longer total sleep time (TST) and greater wake after sleep onset (WASO) would be associated with fewer steps, and higher subjective sleep quality (SSQ) with more steps.

Methods: Daily step counts were modeled using three-level linear mixed-effects models (days nested within bursts within persons). Data were collected between 2019 and 2022 from 388 Czech young adults (18–29 years; 48.2% women) who continuously wore Fitbit Charge 3/4 during four 14-day bursts across one year. Separate models were estimated for TST, WASO, and SSQ as predictors of next-day steps. Models adjusted for age, sex, day type, season, burst number, and wear time, with random intercepts and slopes specified at both burst and person levels, and an AR(1) structure for day-to-day autocorrelation.

Results: Sleep–activity associations varied by analytic level. At the within-person level, higher WASO predicted fewer next-day steps ($\beta = -7.48, p = .027$), whereas daily fluctuations in TST and SSQ were unrelated to steps. At the between-burst level, longer TST ($\beta = -14.82, p < .001$) and greater WASO ($\beta = -49.75, p < .001$) were linked to lower step counts. Between-person associations between sleep indicators and steps were not significant. Age, season, burst number, and wear time consistently influenced step counts.

Conclusion: These findings highlight the importance of extended monitoring to capture both day-to-day and mid-term within-person variability in sleep–activity relationships among young adults. Daily fluctuations in WASO, but not TST or SSQ, were associated with next-day activity, indicating that short-term sleep disruptions may coincide with lower next-day activity. In contrast, between-burst associations for TST and WASO suggest that sleep–activity associations emerge primarily across broader (mid-term) timescales, even after accounting for season, reflecting gradual behavioral shifts rather than short-term fluctuations.

I-P-J.02

Social Jetlag, BMI, and Eating Behaviors from Adolescence to Adulthood

K. Johnson¹, R. Widome¹, D. Neumark-Sztainer¹

¹University of Minnesota, Epidemiology and Community Health, Minneapolis, United States

Purpose: Social jetlag is the misalignment between biological circadian timing and socially constrained sleep schedules, measured by the difference in mid-sleep time between work or school days and free days. Social jetlag has been linked to adverse health outcomes, including higher adiposity, cardiometabolic risk, and mortality, potentially through weight-related behaviors such as eating patterns and dietary quality. Longitudinal data on adolescent social jetlag and later health outcomes in diverse samples remains limited. The present study describes social jetlag from adolescence through adulthood in a socioeconomically and racially diverse sample and examines cross-sectional and longitudinal associations between social jetlag with body mass index (BMI) and eating behaviors.

Methods: 994 participants from the population-based Eating and Activity over Time study completed surveys as adolescents in 2010 ($m_{age} = 14.4$), young adults in 2018 ($m_{age} = 22.1$), and adults in 2023 ($m_{age} = 27.6$). Descriptive statistics summarized social jetlag across time points. One-way ANOVAs tested socioeconomic status (SES) differences in social jetlag at each wave. Linear mixed-effects models assessed associations of social jetlag with BMI and eating behaviors cross-sectionally and longitudinally with an SES x social jetlag interaction term to examine SES-specific effects. Analyses included unadjusted models and models adjusted for demographics and total sleep time. Longitudinal models further adjusted for adolescent BMI and eating behaviors.

Results: Preliminary analyses indicated greater social jetlag in adolescence compared to young adulthood ($p < .001$) and adulthood ($p < .001$), as well as significant SES differences in social jetlag ($p < .05$). Cross-sectional analyses showed greater social jetlag was associated with lower breakfast frequency ($p < .05$) and greater fast-food consumption ($p < .05$) in young adulthood. However, these associations were attenuated after adjusting for demographics and total sleep time. Longitudinal analyses will be conducted and shared at the conference.

J. YOUNG ADULT

Conclusion: Initial findings showed a decline in social jetlag from adolescence to adulthood, as well as socioeconomic differences. Greater social jetlag may contribute to less healthful eating behaviors in young adulthood. Understanding social jetlag and its associations with weight-related behaviors across developmental stages is critical for informing population-level health promotion efforts.

I-P-J.03

Seeking Nutrition and Physical Activity Content on Social Media: Associations with Body Esteem among Young Adults

J. Cloutier-Bélanger¹, V. Drapeau^{1,2}, A. Bédard¹, J. Turgeon³, C. Bégin^{1,4}, A. Bélanger-Gravel^{1,5}, V. Provencher^{1,6}, S. Desroches^{1,6}

¹Institute of Nutrition and Functional Foods (INAF), Centre NUTRISS – Nutrition, santé et société, Québec, Canada, ²Laval University, Department of Kinesiology, Québec, Canada, ³Laval University, Mon équilibre ULaval, Québec, Canada, ⁴Laval University, School of Psychology, Québec, Canada, ⁵Laval University, Department of Information and Communication, Québec, Canada, ⁶Laval University, School of Nutrition, Québec, Canada

Purpose: Social media provides young adults with accessible resources to support a balanced lifestyle. However, it may contribute to negative associations between social media exposure and body image, defined as one's self-evaluation of their body and appearance. This study examines social media use to seek information related to nutrition and physical activity, and its association with body image among French-speaking students at Université Laval, a university in Québec, Canada.

Methods: In this quantitative cross-sectional study, students were recruited through Université Laval's institutional mailing list to complete online questionnaires assessing social media use and body image perception. Body image was measured using two subscales from the Body Esteem Scale for Adolescents and Adults (BESAA): BE-Appearance (overall physical appearance), and BE-Weight (satisfaction with body weight). Generalized linear models compared body-esteem scores between lifestyle-related social media information seekers and those who do not use social media for this purpose. Analyses were done for each lifestyle domain, in the overall sample and by gender. Models were adjusted for age, BMI, ethnicity, student status, education, chronic health condition, social media patterns of use, and eHealth literacy score.

Results: 714 students (24.9±6.8 years; 80.1% women) completed the BESAA. Most participants used social media to seek content on nutrition (68.8%) and physical activity (59.1%). Students who sought nutrition-related information had significantly lower BE-Appearance ($p<0.0001$) and BE-Weight ($p<0.0001$) scores compared to non-seekers, even after adjustments. Among women, this difference was observed only for BE-Weight ($p<0.05$) and was no longer significant after adjustments. Among men, seekers had lower scores for both BE-Appearance ($p<0.001$) and BE-Weight ($p<0.0001$), even after adjustments. Similarly, participants who sought physical activity-related information reported lower BE-Appearance ($p<0.001$) and BE-Weight ($p<0.001$) scores compared to non-seekers, with these differences remaining significant after adjustments. These differences were significant among women but not among men.

Conclusion: Students who use social media to seek information about nutrition and physical activity reported lower body esteem compared to non-seekers, with men showing more significant associations for appearance and weight dimensions. These findings point to the psychological implications of health-related social media use and underscore the importance of integrating these considerations into lifestyle research.

I-P-J.04

Perceived Environmental Barriers and their Influence on Active Commuting among Chilean University Students

M. Parra-Saldías¹, J. de Souza-Lima², S. Mahecha-Matsudo³

¹Universidad de Atacama, Copiapó, Chile, Departamento de Educación Física, Deporte y Recreación, Copiapó, Chile,

²Universidad Andrés Bello, Santiago, Chile, Facultad de Educación y Ciencias Sociales, Instituto del Deporte y Bienestar, Las Condes, Chile, ³Clínica MEDS, Santiago, Chile, Centro de Investigación en Medicina, Deporte, Ejercicio y Salud, Santiago, Chile

Purpose: Active commuting, such as walking or cycling to university, represents an accessible opportunity to increase daily physical activity in young adults. However, perceived environmental and personal barriers may discourage this

J. YOUNG ADULT

behavior. This study aimed to analyze the influence of perceived barriers to walking or cycling on the time dedicated to active commuting among Chilean university students.

Methods: A cross-sectional study was conducted with 307 university students (mean age = 20.3 ± 2.1 years; 57.6% women) from northern Chile (*Atacama Study, 2024*). Daily active commuting time (min/day) was obtained through the *Global Physical Activity Questionnaire*. Fourteen perceived barriers (items 3.1–3.14) related to infrastructure, safety, and personal constraints were assessed using a 4-point Likert scale (1 = strongly disagree; 4 = strongly agree). Spearman correlations were calculated between each barrier and walking time, and a multiple linear regression model was applied to identify independent predictors ($p < 0.05$).

Results: Negative correlations were found between active commuting time and the perception that walking or cycling requires too much physical effort ($\rho = -0.137$; $p = 0.016$) and that students carry too much weight ($\rho = -0.136$; $p = 0.017$). The regression model explained 8.7% of the variance in walking time ($R^2 = 0.087$; $F(14,292) = 1.98$; $p = 0.019$). Two barriers were significant predictors: “dangerous crossings along the route” ($\beta = -9.13$; $p = 0.023$) and “excessive physical effort or insecurity when walking or cycling” ($\beta = -12.80$; $p = 0.001$).

Conclusion: A greater perception of danger and physical effort is associated with less active commuting time among Chilean university students. These findings highlight the need for policies and interventions that improve urban safety and reduce perceived difficulty to promote active transportation and physical activity in young adults.

I-P-J.05

Characterising Health-related Behaviours and Cardiometabolic Profiles of UK University Students

E. Procter¹, A. Price¹, C. Edwardson^{2,3}, I. Podesta Donoso^{2,3}, E. Sweeney¹, P. Hennis¹, R. James^{2,3}

¹SHAPE Research Group, School of Science and Technology, Nottingham Trent University, Nottingham, United Kingdom,

²Leicester Diabetes Centre, University of Leicester, Leicester, United Kingdom, ³NIHR Leicester Biomedical Research Centre, Leicester, United Kingdom

Purpose: University students demonstrate poor health behaviours, including disrupted sleep, high levels of sedentary behaviour, poor diet and risky alcohol consumption, which can increase cardiometabolic disease risk (Savage et al., 2024). Limited research has objectively assessed these risks, particularly among male students and those from minoritised ethnicities (ME). This study aimed to characterise movement, sleep, anthropometry and cardiometabolic health markers in UK university students and examine gender and ethnicity differences to inform inclusive, targeted interventions.

Methods: One hundred and fifteen students (53% female, 73% White) attended the laboratory, fasted, for blood pressure, anthropometry and blood biomarker assessments. Waist circumference (WC), body mass index (BMI), waist-to-hip and waist-to-height ratios (WHR; WHtR), insulin resistance (HOMA-IR), lipid profile and metabolic syndrome (MetS) were calculated. A sub-sample ($n=51$) wore a wrist accelerometer to assess movement and sleep behaviours. Percentages indicate the proportion of students classified as ‘at-risk’. Groups were compared using t-tests, Mann-Whitney U, and Chi-squared tests.

Results: All students spent >6h/day sedentary; however, 98% met UK physical activity guidelines. Physical activity volume was higher in males than females (40.5 vs 32.4mg/day; $p=0.043$) and in White students compared to ME students (39.5 vs 29.6mg/day; $p=0.012$). ME students spent more time sedentary than White students (750.2 vs 638.3min/day; $p=0.001$). Average wake after sleep onset was 64min/day, and females had later sleep and wake times than males (01:43 and 09:20 vs 00:53 and 08:32, $p\leq 0.044$). ME students had shorter sleep duration than White students (5.74 vs 6.75hrs/day, $p=0.006$). The most prevalent ‘at-risk’ anthropometric markers were BMI ≥ 25 (40%) and WHtR ≥ 0.5 (19%). Males had greater central adiposity, higher systolic blood pressure (SBP) and lower HDL ($p\leq 0.008$). White students had higher SBP, fasting glucose and triglycerides than ME students ($p\leq 0.033$). Only 1% met the IDF MetS criteria; however, 33% met one criterion and 12% met two.

Conclusion: High sedentary time and poor sleep patterns, especially among females and ME students, were common despite most meeting physical activity guidelines. Although very few met the full IDF MetS criteria, a substantial proportion presented with individual risk factors, highlighting the need for personalised, preventative interventions in this population.

I-P-J.06

Normalized Muscle-building Behaviours and Muscularity-oriented Disordered Eating in Young Men

D. Dobrzanski¹, E. Pila¹

¹Western University, School of Kinesiology, London, Canada

Purpose: Normalized and socially valorized muscle building behaviours may represent a more problematic characterization of disordered eating in young men. While physical activity is generally promoted for its physical and mental health benefits, the manner in which young men engage in muscle-building practices often reflects internalized social norms around masculinity and body ideals. Behaviours such as engagement in bulk/cut cycles, “cheat meals,” and protein supplementation are socially accepted and even promoted within fitness and bodybuilding communities, yet they may serve as markers of underlying disordered eating tendencies. The present study aimed to investigate the associations between common muscle-building behaviours and muscularity-oriented disordered eating in a sample of young men. By examining these behaviours collectively, we sought to clarify which normalized practices are most closely linked to disordered physical activity and nutritional behaviours.

Methods: In a cross-sectional survey design, young men ($N = 214$; $M_{\text{age}} = 21.55$, $SD_{\text{age}} = 3.23$) completed assessments of muscularity oriented disordered eating, engagement in bulk/cut cycles and cheat meals, and exercising, using protein powder/shakes, using steroids, and using another muscle substance for the purpose of gaining muscle mass. A multiple linear regression was conducted to examine whether various muscle building behaviours predicted muscularity-oriented disordered eating.

Results: 61% of men reported engaging in bulk/cut cycles and 73% of men reported engaging in chat meals. The most common muscle building behaviour was exercise with only 3 men reporting not exercising for the purpose of gaining muscle. The overall model was significant, $F(7,214)=8.603$, $p<.001$, $R^2=0.22$. We found that engagement in bulk/cut cycles ($p=0.020$) and cheat meals ($p<0.001$) were associated with muscularity-oriented disordered eating. Exercising ($p=0.585$), using protein powder/shakes ($p=0.097$), using steroids ($p=0.054$), and using another muscle enhancing substance ($p=0.664$) were not significantly associated with muscularity-oriented disordered eating.

Conclusion: Results indicate that engagement in bulk/cut cycles and cheat meals may reflect or reinforce a focus on muscularity-related disordered eating behaviours, and that not all muscle-related behaviours are equally linked to disordered eating. Future research using longitudinal or experimental designs could determine causation and inform interventions to promote behaviour change in men’s physical activity and nutritional behaviour.

I-P-J.07

Adolescents’ Perceptions of Intuitive Eating: Preliminary Findings from a Qualitative Study Using the French-Canadian Intuitive Eating Scale-3 in Quebec

A. Boivin^{1,2}, N. Carbonneau³, M. Turcotte², J. Lévy-Ndejuru^{1,2}, S. Lemieux^{1,2}, É. Carbonneau^{1,2}

¹Université Laval, School of Nutrition, Québec City, Canada, ²Centre Nutrition, Santé et Société (NUTRISS), Institute of Nutrition and Functional Foods (INAF), Université Laval, Québec City, Canada, ³Université du Québec à Trois-Rivières (UQTR), Department of Psychology, Trois-Rivières, Canada

Purpose: Intuitive eating is a positive approach that promotes eating without rigid rules or self-judgment, while respecting the body’s internal cues. The most used tool to assess adherence to intuitive eating principles is the *Intuitive Eating Scale* (IES). A new version, the IES-3, comprising 12 items, was recently published in English, translated into French, and validated among adults in Quebec (Canada). As part of a face validity assessment of this French version among Quebec adolescents which took place during summer 2025, qualitative data were collected to explore how they perceive intuitive eating and how it can be integrated into their daily lives.

Methods: Individual interviews were conducted to assess face validity and then, to gather more insights on barriers and facilitators of intuitive eating behaviors, based on the Theory of Planned Behavior (TPB). Participants were recruited mainly from sports clubs and youth centers. Thematic analysis is ongoing and conducted on the adolescents’ comments. All interview content is analyzed, including responses related to face validity and comments related to the TPB questions.

Results: A total of 14 interviews were conducted (mean duration = 50 minutes). Participants included boys ($n = 5$) and girls ($n = 9$), aged 13 to 16 years (mean = 14.5) with diverse backgrounds. Although analysis is ongoing, preliminary

J. YOUNG ADULT

findings have emerged. Among the IES-3 subscales, *Reliance on Hunger and Satiety Cues* and *Body-Food Choice Congruence* subscales appeared to pose greater challenges, as participants seemed to exhibit lower adherence to these dimensions. A frequently mentioned barrier was unclear hunger or satiety signals, or difficulty noticing the effects of food on the body. Emotional eating (*Eating for Physical Rather than Emotional Reasons*) was rarely reported, although some participants mentioned eating out of boredom. Regarding the *Unconditional Permission to Eat* subscale, those with lower adherence often cited limiting certain foods for health reasons or body weight concerns. The analysis, notably the identification of facilitating factors, is expected to be completed by March 2026.

Conclusion: These preliminary results allowed mainly the identification of key barriers to the adoption of intuitive eating during adolescence, which could help to develop more effective interventions for youth.

I-P-J.08

State Muscularity Satisfaction and Engagement in Muscle-building Behaviours in Young Men's Daily Life

Z. Staffell¹, E. Pila¹

¹Western University, School of Kinesiology, London, Canada

Purpose: Young men face increasing societal pressures to achieve a muscular physique, a preoccupation that has been associated with worsened mental health and psychological wellbeing. According to sociocultural body image theories, dissatisfaction with muscularity leads to compensatory muscle-building behaviours (e.g., weightlifting, protein consumption, anabolic steroid use). Despite robust evidence demonstrating this relationship at the individual level, no studies have assessed if moment-to-moment fluctuations in muscularity satisfaction impact engagement in muscle-building behaviours. This is surprising given that engagement in muscle-building behaviour varies within individuals over time. The primary purpose of this study was to examine the association between state muscularity satisfaction and engagement in muscle-building behaviours in men's daily life.

Methods: Adult men who regularly engage in muscle-building behaviour ($N = 244$; $M_{\text{age}} = 21.55$, $SD_{\text{age}} = 3.23$) participated in an ecological momentary assessment, reporting on their muscularity satisfaction and engagement in a range of muscle-building behaviours 5x/day for a period of two weeks.

Results: As expected, there was substantial variation in engagement in muscle-building behaviours within-individuals over the study period ($ICC = 0.170$). Findings from random intercept models revealed that men who reported higher overall levels of muscularity satisfaction reported significantly lower odds of engaging in muscle-building behaviours overall ($ORs = 0.82-0.87$, $ps < .05$). Contrary to hypotheses, there were no significant within-person relationships between muscularity satisfaction and muscle-building behaviour at the same assessment ($OR = 0.96$, $p = .62$), or in subsequent assessments ($OR = 0.99$, $p = .81$).

Conclusion: Men who experience higher overall levels of muscularity satisfaction may be less likely to engage in muscle-building behaviours over time. These findings extend muscularity-oriented compensatory models by demonstrating robust individual level differences and providing no evidence for transient state-level effects between muscularity evaluation and subsequent behaviour. It is likely that compensatory muscle-building behaviours are routine, stable, and habitual, particularly in young men who regularly engage in these behaviours. Future research is needed to test state-level dynamics of compensatory health behaviours.

I-P-J.09

Exploring Barriers and Facilitators to Meeting the 24-Hour Movement Guidelines among Adolescent Girls in Mexico

A. Comfort¹, J. Ortiz Brunel², J.R. López y Taylor³, E. Jáuregui Ulloa³, L. Lévesque¹

¹Queen's University, School of Kinesiology and Health Studies, Kingston, Canada, ²National Institute of Public Health (INSP), Department of Physical Activity and Healthy Lifestyles, Cuernavaca, Mexico, ³University of Guadalajara, Health Sciences University Center (CUCS), Institute of Applied Sciences to Physical Activity and Sport, Guadalajara, Mexico

Purpose: In Mexico, many adolescent girls do not meet guidelines for physical activity, sleep, and screen time, and are less likely than boys to achieve physical activity recommendations. Despite this, there is limited qualitative research examining barriers and facilitators. This study aimed to explore these factors across the 24-hour day among Mexican adolescent girls.

J. YOUNG ADULT

Methods: Four focus groups were conducted with 25 adolescent girls (aged 15-19) enrolled in public high schools in an urban municipality in the Guadalajara Metropolitan area. A semi-structured guide was used to examine barriers and facilitators to meeting physical activity, sleep, and screen time guidelines. Data were analyzed using Braun and Clarke's reflexive thematic approach, applying a socioecological framework deductively.

Results: Adolescent girls described personal knowledge, awareness, and strategies related to getting active, sleeping well, and limiting screen time. Families played a significant role in shaping girls' movement behaviours across the 24-hour day, at times supporting physical activity and limiting screen use, but also contributing to poor sleep and increased screen time. School-related barriers included inadequate physical activity spaces, low quality of physical education classes, and early start times that negatively impacted sleep. Community-level barriers included limited access to safe physical activity spaces and security concerns, while environmental noise and long commutes impeded sleep. Gender-based physical activity barriers, including restrictive stereotypes and social norms, experiences of sexual harassment during exercise and fear of gender-based violence, were particularly salient.

Conclusion: Adolescent girls face multiple barriers to meeting movement behaviour guidelines, across family, school, and community settings. Efforts to promote a healthy balance of movement behaviours must extend beyond the individual level to include changes to the broader environments in which girls live, learn, and move. Future research should explore how gender-based differences, including power dynamics and social roles, affect adolescents' experiences, needs and opportunities across the gender spectrum.

I-P-J.10

Young Adults' Perceptions of a Healthy Lifestyle and Its Associated Factors: A Multi-center Qualitative Inquiry

N. Rathi¹, A. Sharma², S. Sandilya², S. Ghosh³, R. Chowdhury³, A. Worsley⁴, M. Bruening⁵

¹Ahmedabad University, Bagchi School of Public Health, Ahmedabad, India, ²Banaras Hindu University, Department of Home Science, Mahila Mahavidyalaya, Varanasi, India, ³Symbiosis Skills and Professional University, School of Nutrition & Dietetics, Pimpri-Chinchwad, India, ⁴Deakin University, School of Exercise and Nutrition Sciences, Geelong, Australia, ⁵Pennsylvania State University, Department of Nutritional Sciences, College of Health and Human Development, University Park, United States

Purpose: In the last decade, India has witnessed a significant rise in the prevalence of obesity and the associated chronic degenerative diseases among its urban youth population. One of the primary causes of this escalating disease burden is the adoption of unhealthy lifestyles by Indian young adults.

Methods: Informed by the social constructivist theory, this descriptive, qualitative study was designed to understand the urban Indian young adults' views about a healthy lifestyle and the factors associated with its adoption. Both purposive and snowball sampling techniques were employed to recruit young adults (aged 21-29 years) from eight Indian metropolises (New Delhi, Mumbai, Kolkata, Chennai, Ahmedabad, Pune, Hyderabad, Bengaluru). In-depth, semi-structured interviews were either carried out in person or virtually till thematic saturation was attained. Interviews were digitally recorded, transcribed, and transferred to NVivo software for the purpose of data analysis. Interview transcripts were analyzed using inductive coding.

Results: Seventy-nine young adults (38 females, 41 males) completed the interviews. Emerging themes and sub-themes were: (i) Perceptions of a healthy lifestyle (consuming a balanced diet, leading an active life; having adequate sleep); (ii) Facilitators of a healthy lifestyle (upbringing and support of family members, health promotion by famous personalities, built-in environment, intrinsic motivation, physical appearance); (iii) Barriers to a healthy lifestyle (lack of time, peer pressure, food environment challenges); (iv) Strategies adopted to maintain a healthy lifestyle (limiting screen time, regular participation in exercise and other forms of physical activity, diet management); and (v) Recommendations for future lifestyle interventions (developing healthy and hygienic food environments, nutrition and health education).

Conclusion: This multisite study offers novel insights into understanding the barriers and facilitators at the individual, social and environmental levels to adoption of healthy lifestyles among urban Indian young adults. In addition, prospective lifestyle interventions can be designed by removing the barriers and strengthening the facilitators to support vulnerable Indian young adults in adopting and maintaining a healthy lifestyle, subsequently reducing their morbidity risk. Potential avenues for interventions could include enhancing food and health literacy of young Indian consumers as well as increasing the provision of more healthy food and beverage items in workplaces and educational institutions.

Effectiveness of an Active Breaks Programme on the Psychological Performance among University Students

J. Vidal-Conti¹, O. Garcia-Taibo¹, A.M. Galmés-Panadés¹

¹University of the Balearic Islands, Palma, Spain

Purpose: Mental fatigue resulting from prolonged cognitive activity leads to tiredness and decreased performance, particularly among university students. Active breaks (ABs) are short exercise sessions designed for use in the classroom, helping to alleviate stress and counteract the effects of prolonged sitting. This study aimed to evaluate the effectiveness of an AB programme on the psychological determinants of academic performance (motivation, attention, mood and mental fatigue) among university students.

Methods: A quasi-experimental design with pre- and post-repeated measurements was conducted with 96 undergraduate students (73.6% male, 26.4% female) in Mallorca, Spain. The intervention involved 3- to 5-minute ABs over 10 weeks, with two breaks per week. The order of conditions (AB/without AB) was counterbalanced. A visual analogue scale was used at the beginning, middle and end of the class to assess relevant psychological determinants. In total, 753 VAS questionnaires were completed across all sessions and participants (753 records), corresponding to repeated measures at the beginning, middle and end of each class. These records were completed during 20 sessions, of which 434 (57.6%) corresponded to sessions with ABs and 319 (42.4%) to sessions without ABs. The present study was approved by the Research Ethics Committee of the University of the Balearic Islands (Reference: 074CER24).

Results: All mid-class measurements were significantly better in the AB condition compared to the condition without ABs. The AB condition had higher mean scores than the non-AB condition for motivation (7.07 vs 5.91), attention (6.83 vs 5.90) and mood (7.19 vs 6.41). The AB condition also showed less mental fatigue (4.80 vs 5.38).

Conclusion: ABs are efficacious in improving attention, motivation and mood while reducing mental fatigue among university students, with immediate benefits observed both after the break and at the end of the class, compared to the control condition. However, the positive effects appear to be acute and short-term, indicating that ABs need to be implemented routinely in classroom settings to sustain their benefits on psychological performance.

I-P-J.12

Movement Behaviours Relate to Cortisol Stress Output and NR3C1 Methylation Profiles in Young University Students

S. Rostami^{1,2,3}, A. Bermudo-Gallaguet^{1,2,3}, N. Camins-Vila⁴, B. Ferrer-Uris⁴, A. Busquets⁴, M. Via^{1,2,3}, E. Samacá Ortiz⁵, M. Mataró^{1,2,3}

¹University of Barcelona, Department of Clinical Psychology and Psychobiology, Barcelona, Spain, ²University of Barcelona, Institute of Neuroscience, Barcelona, Spain, ³Institut de Recerca Sant Joan de Déu (IRSJD), Esplugues de Llobregat, Spain, ⁴University of Barcelona, National Institute of Physical Education of Catalonia (INEFC), Barcelona, Spain, ⁵Polytechnic University of Catalonia (UPC), Barcelona East School of Engineering, Barcelona, Spain

Purpose: Young university students often experience high psychosocial stress and lifestyle irregularities that may affect hypothalamic-pituitary-adrenal axis regulation and epigenetic regulation of the glucocorticoid receptor gene (*NR3C1*). This study examined associations among lifestyle factors, *NR3C1* DNA methylation, and cortisol output, and whether these markers relate to psychological distress and cognitive function.

Methods: A cross-sectional study included 97 university students (48 women; mean age = 21.6 years). *NR3C1* promoter methylation was measured by pyrosequencing, and two components (C1, C2) were derived. Salivary cortisol was collected during the Trier Social Stress Test, and the area under the curve with respect to ground (AUCg) was calculated. Lifestyle behaviours, cardiorespiratory fitness (CRF), symptoms of depression, anxiety, and stress, and cognitive domains were assessed. Multiple regression and moderation analyses tested associations and interactions with sex and BMI.

Results: Higher sedentary behavior was associated with lower *NR3C1* C2 methylation, and higher physical activity and CRF were related to lower cortisol AUCg. *NR3C1* C1 methylation was associated with poorer executive function and inhibition, and cortisol AUCg was positively associated with depressive symptoms. Other associations were not significant. Exploratory moderation analyses indicated that higher *NR3C1* C2 methylation was associated with better attention at lower BMI, higher *NR3C1* C1 methylation with poorer inhibition in men, and higher *NR3C1* C2 methylation with better attention-processing speed in women.

J. YOUNG ADULT

Conclusion: Movement-related behaviours emerged as the primary lifestyle correlates of stress system markers. *NR3C1* methylation showed sex and domain-specific associations with cognition, suggesting glucocorticoid receptor-related epigenetic variation may relate to cognitive function.

I-P-J.13

Higher Education Employees Attitudes and Willingness to Act on College Student Food Insecurity

E. Heying¹, M. Baker², Z. Qamar³

¹College of Saint Benedict and Saint John's University, Nutrition, Saint Joseph, United States, ²College of Saint Benedict and Saint John's University, Psychology, Saint Joseph, United States, ³San Francisco State University, Nutrition, San Francisco, United States

Purpose: Support for food insecurity in higher education exists, but campus employees' roles are largely unknown and few interventions involve grass-roots campus community input. This study explored higher education employee attitudes towards student food insecurity and willingness to provide food insecurity support to clarify knowledge gaps and barriers for decreasing food insecurity on college campuses.

Methods: This cross-sectional study utilized an anonymous, online survey to collect data. Higher education employees over 18 years old and living in the United States were eligible. A nine-item survey with Likert-type responses was used to assess participant attitudes/awareness and willingness to act/show support for food insecurity. Exploratory factor analysis of all survey items revealed two factors of four items each independently loading. These subscales were labeled „Attitude“ and „Action“ and used for further statistical analysis. Mean subscale scores were then compared among employment role (faculty, staff, or administrator), campus food security involvement (yes or no), and personal experience of food insecurity (yes or no). Nonparametric tests, such as Mood's median or Mann-Whitney U, were used to compare differences among attitude subscale means comparisons (negatively skewed). One-way ANOVA and independent samples t-test were used for action subscale means comparisons (normally distributed).

Results: The participants (n = 584) were predominantly female, white, and 63% (n = 367) were faculty. Attitude median subscale scores did not significantly differ by employment role and scores were > 4.5 out of a possible high score of 5 in all groups. Action subscale mean scores differed significantly by role (p = 0.021), with administrators having significantly higher scores than staff or faculty (p = 0.045). Both attitude and action subscale scores were significantly higher in participants involved with food insecurity efforts and having past food insecurity experience (p < 0.001 for all variables, respectively).

Conclusion: Higher education employees have positive attitudes toward addressing student food insecurity, but willingness to act is potentially influenced by prior involvement and personal experience, revealing a critical gap between awareness and action. Institutions may benefit from targeted training and engagement strategies that involve all employees as active participants in food security efforts.

I-P-J.14

Menstrual Bleeding Phases and Self-reported Physical and Mental Readiness in Active Young Adult Females: Preliminary Data from the PERCIVIR Project

R. Cupeiro¹, J.A. Benítez-Muñoz^{1,2}, A. Armero-Sotillo¹, M.Á. Rojo-Tirado¹, H. Goicoechea-Pellejero³, D.J. Ramos-Campo¹, M. Perrino-Peña⁴, L. Jurado-Fasoli^{5,6,7}, A.B. Peinado¹, I. Rodríguez-Gómez⁸, G. Molina-Torres⁹, J.Á. Rubio-Arias¹⁰

¹Universidad Politécnica de Madrid, Faculty of Physical Activity and Sport Science (INEF), LFE Research Group, Department of Health and Human Performance, Madrid, Spain, ²Universidad Alfonso X el Sabio – Mare Nostrum, Facultad de Salud y Deporte, Málaga, Spain, ³University of the Basque Country (UPV/EHU), Faculty of Education and Sport, Department of Physical Education and Sport, Vitoria-Gasteiz, Spain, ⁴Universidad de León, Faculty of Physical Activity and Sports Sciences, Estudios Documentales En Ciencias De La Actividad Física Y De La Educación (DOCUCAFE) - 387 Research Group, Department of Physical and Sports Education, León, Spain, ⁵University of Granada, Faculty of Medicine, Sport and Health University Research Institute (iMUDS), Department of Physiology, Granada, Spain, ⁶Instituto de Salud Carlos III, Centro de Investigación Biomédica en Red Fisiopatología de la Obesidad y Nutrición (CIBERObn), MadridSpainSp, Spain, ⁷Instituto de Investigación Biosanitaria ibs.GRANADA, Granada, Spain, ⁸University of Castilla-La Mancha, Faculty of Sport Sciences, GENUO Toledo Research Group, Centro de Investigación Biomédica en Red Fragilidad y Envejecimiento

J. YOUNG ADULT

Saludable (CIBERFES), Grupo Mixto de Fragilidad y Envejecimiento Exitoso UCLM-SESCAM, Toledo, Spain, ⁹University of Almería, Faculty of Health Sciences, Department of Nursing, Physiotherapy and Medicine, Almería, Spain, ¹⁰University of Almería, Health Research Centre, Humanidades- 628 Research Group, Department of Education, Almería, Spain

Purpose: Women remain underrepresented in sports science, although menstrual bleeding-related symptoms are reported to influence sport-related decisions and participation. Understanding perceived readiness across bleeding phases is therefore relevant. Most research relies on retrospective questionnaires or elite samples, limiting validity and generalizability¹. Daily monitoring in non-elite active women is scarce, constraining evidence-based exercise recommendations. We investigated whether physical and mental readiness to train or compete differ across bleeding (B), non-bleeding (NB), and pre-bleeding (PB) phases in active young adult females.

Methods: This is a preliminary analysis of a subsample from the PERCIVIR project². A prospective daily monitoring was used with 19 active females (age: 30.90±7.77 years; body mass: 59.10±8.47 kg; height: 165.00±6.43 cm; cycle length: 26.20±2.67 days). Participants completed a daily online questionnaire assessing their physical and mental readiness to train or compete using two 0–10 visual analogue scales (0=not ready at all; 10=very ready; 0.1 precision). Phases were established based on self-reported data for B or NB, and considering the seven days before bleeding-onset for PB. Repeated-measures ANOVA was used.

Results: Although phase effect was not statistically significant ($F=2.15$, $p=0.147$, $\eta^2p=0.107$), a medium-to-large effect size was observed for physical readiness (B: 6.64±1.39, PB: 7.23±1.54; NB: 7.47±1.15). Mental readiness followed a non-significant similar pattern (B: 6.79±1.62; PB: 7.17±1.59; NB: 7.43±1.47), with a medium effect size ($F=1.38$, $p=0.264$, $\eta^2p=0.071$).

Conclusion: In this preliminary analysis, cycle phases were not significantly associated with perceived physical or mental readiness to train or compete. However, the lower scores observed during bleeding, along with the effect sizes, suggest a possible phase-related pattern requiring confirmation in larger samples. This contrasts with findings in elite athletes¹, indicating potentially distinct perceptions among non-elite populations. Incorporating menstrual cycle awareness into exercise promotion may facilitate personalized guidance and improve participation.

Demographic Characteristics Contribute to Poor Food Choices: A Retrospective Observational Study of UK Secondary School Purchasing Data

A. Bird^{1,2,3}, J. Baird^{1,3,2}, K. Woods-Townsend^{1,4,3}, L. Morrison^{5,6}, C. Vogel^{7,8,2}, S. Crozier^{1,2,3}

¹University of Southampton, Faculty of Medicine, Southampton, United Kingdom, ²MRC Lifecourse Epidemiology Centre, Southampton, United Kingdom, ³NIHR Southampton Biomedical Research Centre, University of Southampton and University Hospital Southampton NHS Foundation Trust, Southampton, United Kingdom, ⁴School of Healthcare Enterprise and Innovation, University of Southampton, Faculty of Medicine, Southampton, United Kingdom, ⁵University of Southampton, Faculty of Environmental and Life Sciences, Department of Psychology, Southampton, United Kingdom, ⁶University of Southampton, Primary Care Research Centre, Faculty of Medicine, Southampton, United Kingdom, ⁷University of London City St Georges, Population Health and Policy, London, United Kingdom, ⁸University of London City St Georges, Centre for Food Policy, London, United Kingdom

Purpose: Dietary behaviours developed during adolescence are likely to be maintained throughout the lifecourse. Current evidence shows adolescents have poor diet quality. Adolescents spend 20% of waking hours at school; it is crucial that we examine how this setting shapes dietary behaviours. Relevant existing evidence from this setting relies on self-report methods, leaving them vulnerable to bias. This study aimed to address this issue by using objective purchasing data to assess food choices.

Methods: This study used a retrospective observational design, set in a comprehensive secondary school in England. Participants were pupils aged 11–16 years. Canteen purchasing data spanning one year were extracted from a biometric payment system. Health scores were assigned to each of the 79 food items using two food-based and two nutrient-based methods. Overall nutritional scores were calculated using the average score per purchase. Purchasing data were linked to students' demographic characteristics. Linear and logistic regression analyses assessed associations between demographic characteristics and diet score.

Results: 966 participants purchased at least one item from the canteen and could be given a nutritional score (measured in standard deviations). The three most sold items (all cakes and biscuits, soft drinks and hashbrowns) were ultra-processed and high in fat, salt and sugar, indicating poor food choices. After adjusting for confounders

J. YOUNG ADULT

identified using a Directed Acyclic Graph, being older (β 0.09 95% CI 0.04, 0.13 $P < 0.001$), identifying as a boy (β 0.17 95% CI 0.11, 0.23 $P < 0.001$), and being from a white background (β -0.22 95% CI -0.46, 0.03 P 0.08) were associated with making less healthy choices. Being eligible for free school meals (β -0.53 95% CI -0.70, -0.36 $P < 0.001$) was associated with healthier choices.

Conclusion: This study presents a protocol for using objective purchasing data to assess diet quality. Despite the presence of the school food standards, food choices were poor, especially for older pupils, boys, and those from a white background. In future, the social and contextual drivers of these choices and whether they are considered representative of food choices across English schools should be assessed.

I-P-J.16

Food Consumption of Finnish Young Adults by Sex, Parental Socioeconomic Status, and Weight Status

C. Sarkkola^{1,2}, S. Lommi^{1,3}, N.E Kaartinen⁴, M. Maukonen^{1,4}, S. Männistö⁴, H. Viljakainen^{1,3}

¹Folkhälsan Research Center, Helsinki, Finland, ²University of Helsinki, Department of Public Health, Faculty of Medicine, Helsinki, Finland, ³University of Helsinki, Faculty of Medicine, Helsinki, Finland, ⁴Finnish Institute for Health and Welfare (THL), Helsinki, Finland

Purpose: Previous research has indicated differences in food consumption across sociodemographic groups in Finland. However, less is known about how food consumption varies among young adults—an important life stage characterised by increased independence and responsibility. Our aim was to explore how food consumption differs in emerging adulthood by sex, parental socioeconomic status (SES), and weight status in Finland.

Methods: This study included 3,416 participants aged 18–24 years from the prospective Fin-HIT study conducted between 2020 and 2024. The habitual diet over the previous 12 months was measured with a validated, 134-item food frequency questionnaire (FFQ). The average daily food consumption and energy intake were calculated using the Finnish National Food Composition Database (Fineli®). Height and weight were self-reported, and body mass index was calculated. We included previously collected data on parental SES. We applied analysis of variance (ANOVA) to examine differences between groups.

Results: The mean (SD) age of participants was 19.5 (0.9) years, and 63% were women. The largest differences in food consumption were observed between the sexes. In relation to total energy intake, women had a higher consumption of vegetables (38 vs. 22 g/MJ), fruits and berries (27 vs. 13 g/MJ), and chocolate and sweets (3 vs. 2 g/MJ) compared to men ($p < 0.001$). In contrast, men had a higher consumption of milk and milk products (64 vs. 45 g/MJ), red meat (10 vs. 7 g/MJ), and fish (5 vs. 4 g/MJ) ($p < 0.001$). Participants with high parental SES consumed more vegetables, fruits and berries, legumes, and fish, but less red meat compared to those with low parental SES ($p < 0.001$). Participants with normal weight ate more vegetables, fruits and berries than those with underweight, overweight, or obesity ($p < 0.001$). Chocolate and sweets consumption was similar in all weight status groups.

Conclusion: Food consumption varied by sex, SES, and weight status in emerging adulthood. Public health efforts should aim to promote healthier food choices among men, individuals with lower parental SES, and those living with underweight, overweight, or obesity during this critical phase of emerging adulthood.

I-P-J.17

Changes in Diet Across the Transition from Adolescence to Early Adulthood in the UK: Longitudinal Associations with Education and Employment Pathways and Changing Living Arrangements

T. Braune¹, A.F. Oxenham¹, E. van Sluijs², E.M. Winpenny^{1,2}

¹Imperial College London, School of Public Health, London, United Kingdom, ²University of Cambridge, MRC Epidemiology Unit, Cambridge, United Kingdom

Purpose: Adolescence is an important period for dietary behaviour development, which influences long-term health, characterised by life transitions (e.g. entering further education or the workforce), exposing individuals to new environments, which may shape diet. This study examined changes in diet quality from the final year of school (UK school year 13) to 12 months later and investigated variations by employment/education pathways and living arrangements.

J. YOUNG ADULT

Methods: The Diet and Eating Behaviours across Early Adulthood Transitions (DEBEAT) study recruited participants from schools/colleges across England in 2023-4. This analysis included 773 participants who were attending school/college and living with their families at wave 1 and completed dietary recalls and questionnaires at waves 1 and 2. Diet quality was assessed using the Dietary Approaches to Stop Hypertension (DASH) diet score (range 0-80). Linear regression models examined associations between (1) education/employment at wave 2 (education only; education and work; work only) and (2) living arrangements at wave 2 (family/non-family), with DASH score at wave 2. Models were adjusted for parental sociodemographic characteristics, physical and mental health, and baseline DASH score. Multiple imputation addressed missing covariate data.

Results: DASH score showed a small improvement between wave 1 and wave 2: $\beta = 0.42$ [95% CI: 0.33, 0.51]. Compared to individuals in education only, those combining education and employment showed a similar change in DASH score, whereas those working and not in education showed a decrease in DASH score: $\beta = -1.66$ [95% CI: -3.97, 0.65]. Most participants in work only (93%) and combining employment and education (60%) remained living with their family, whereas 66% of those in education only were living away from home. DASH score decreased among those moving away from family: $\beta = -1.42$ [95% CI: -3.14, 0.29] compared to those who stayed living at home.

Conclusion: Diet quality modestly improved across the transition out of school. However, entering employment, rather than further education, and moving out, rather than living with family were associated with decreases in diet quality. Although initial findings lack power, these changes suggest potential early drivers of dietary inequalities and further research is warranted.

I-P-J.18

Four-week Time Restricted Eating Intervention Is Associated with Improvements in Cardiometabolic Risk Factors and Dysregulated Eating among Emerging Adult Women: A Single-armed Trial

D. Vizthum¹, H. Cash¹, C. Earthman¹, M. Melough¹, F. Patterson¹, K. Allison², C. Pacanowski¹

¹University of Delaware, Health Behavior and Nutrition Sciences, Newark, United States, ²The University of Pennsylvania, Perelman School of Medicine, Philadelphia, United States

Purpose: Time restricted eating (TRE) is associated with favorable cardiometabolic (CM) outcomes, suggesting use as a CM disease prevention strategy. However, the impact of TRE on dysregulated eating among emerging adult women at risk for disordered eating is unknown. This study examined the effects of a 4-week TRE intervention on dysregulated eating behaviors and body composition in emerging adult women with moderate-high dietary restraint.

Methods: 36 emerging adult women with eating windows ≥ 12 hours and moderate-high dietary restraint completed 1 baseline week and 4 weeks of TRE (10hr eating window ending by 8pm). Participants completed the Dutch Eating Behavior Questionnaire, 3-day food logs, anthropometric measurements and DXA scans at baseline and post-intervention. Ecological momentary assessments (EMA) were administered 5x/day during baseline and week 1 and 4 of TRE to assess eating in the absence of hunger (EAH).

Results: Adherence with TRE and EMA was above 85%. Significant decreases occurred in emotional eating ($p=0.009$, Cohen's $d=-0.470$), caloric intake ($p<0.001$, Cohen's $d=-0.750$), body weight ($p<0.001$, Cohen's $d=-0.649$), and visceral fat ($p=0.026$, Cohen's $d=-0.452$) between baseline and end of TRE. The odds of EAH were significantly lower during TRE than baseline (week 1 OR: 0.48, 95% CI: 0.32-0.71; week 4 OR: 0.46, 95% CI: 0.29-0.71, both $p<0.001$). Compared to baseline, EAH decreased during fasting and early TRE eating periods ($p=0.002-0.033$), but not later in the eating window ($p=0.579-0.763$).

Conclusion: 4-week TRE intervention with modest eating window reduction produced beneficial changes in eating behavior, body weight, and visceral fat in emerging adult women.

II-P-J.01

The Influence of Social Media on Female Athletes' Body Image: Exploring the Role of Social Media in Shaping Perceptions and Impacting Eating Behaviours

A.R. Fell¹

¹Massey University, School of Psychology, Wellington, New Zealand

J. YOUNG ADULT

Purpose: This research examined how social media influences body image and eating behaviors among competitive female athletes in Aotearoa New Zealand. Despite evidence that female athletes are at heightened risk of disordered eating, little is known about how social media contributes to these experiences within sporting contexts. This study addressed this gap by asking: (1) How do perceptions of beauty standards influence athletes' experiences of body image? (2) What are the implications of engaging with social media for athletes' body image? and (3) What social and psychological factors shape positive and negative body image experiences on social media? In doing so, the research highlights future directions for athlete support and education that are responsive to both digital pressures and the physical and emotional demands of competitive sport.

Methods: Eight semi-structured Zoom interviews were conducted with competitive female athletes aged 18–24. Data were analyzed using reflexive thematic analysis (Braun & Clarke, 2006), with the researcher's experience as a former competitive athlete supporting a reflexive and nuanced interpretation of participants' accounts.

Results: Three overarching themes were identified. Risk factors included the normalization of overtraining, misinformation and insufficient education, and the influence of coaches and family on nutrition and training. Protective factors included social support, self-regulatory strategies, and access to guidance and resources. Lastly, experiences of body image and social media impact included habitual comparisons both online and offline, internalization of appearance norms and expectations, and patterns of disordered eating and exercise behaviors.

Conclusion: Athletes reported dual pressures: to achieve the athletic ideal within their sport, and to conform to unrealistic beauty standards reinforced by social media. Comparison was habitual, as athletes evaluated their bodies, training, and food intake against peers and online figures, sometimes leading to disordered eating and over-exercise. Most had limited access to nutritional or psychological support, relying instead on social media for guidance. Coaches and family emerged as protective influences, fostering healthier relationships with food. Findings highlight the need for early intervention, such as online training modules and workshops focused on nutrition, body image, and social media literacy within sporting or school environments.

II-P-J.02

Sedentary Behaviour among Students and their Socioecological Determinants: A Cross-sectional Study

J. Möckel¹, B. Wallmann-Sperlich², R. Rupp¹, J. Bucksch¹

¹Heidelberg University of Education, Heidelberg, Germany, ²Julius-Maximilians University Würzburg, Würzburg, Germany

Purpose: Prolonged sedentary behaviour (SB) is linked to adverse health outcomes and is particularly prevalent among university students. While individual determinants have been widely studied, less is known about the social and environmental influences on SB during structured academic activities. This study aimed to examine the prevalence of SB and its socio-ecological determinants within the university context.

Methods: A cross-sectional online survey was conducted among 434 students at a German university. Participants self-reported their sedentary time during the academic day and within 90-minute lectures. Variables at individual, social, and environmental levels were assessed. Logistic regression models identified associations with (1) overall sitting time, (2) uninterrupted sitting during 90-minute lectures and (3) number of sitting breaks during 90-minute lectures.

Results: Students reported sitting for an average of 12.4 hours per day, with 55% taking no breaks during lectures. Higher motivational self-efficacy and autonomy were associated with reduced SB and more frequent interruptions. Social norms supporting movement predicted less sitting, while subjective norms encouraging sitting were linked to more sedentary patterns. A movement-supportive environment showed strong associations with sitting interruptions during lectures. The high prevalence of SB and its socio-ecological embedding underscore the need for multi-level interventions addressing individual agency, social norms, and institutional structures in university settings.

Conclusion: Our findings highlight the need for interventions that address both individual dispositions and the structural embedding of SB in the university context. While motivational self-efficacy emerged as a relevant individual factor, its impact depends on supportive social and environmental conditions. Behaviour change efforts are unlikely to succeed if they focus solely on internal motivation without tackling institutional and cultural barriers. Universities should consider reforms that reduce sedentary constraints and expand behavioural options, such as integrating physically active teaching formats and redesigning learning spaces. Institutional policies can also play a key role by legitimizing physical activity during academic activities.

The Nova Scotia Youth, Nature, and Wellbeing Survey: Filling Gaps in Our Understanding of Youth's Experiences with and Access to Nature, and Benefits to Wellbeing

M. Stone¹, M. Kwan¹, J. Campbell¹, S. Pawelko¹, A. Cohen¹, J. Cawley¹, B. Feicht¹, S. Truong¹

¹Dalhousie University, Department of Health and Human Performance, Faculty of Health, Halifax, Canada

Purpose: According to the biophilia hypothesis, contact with nature is a basic need, part of our evolutionary history, and critical for mental, emotional, and physical wellbeing. In Nova Scotia (NS), a province in Atlantic Canada, youth engagement with nature continues to decline, while mental health challenges rise. As evidence of the benefits of nature exposure grows, so does its potential to reduce the healthcare burden related to poor mental health and wellbeing among youth. While some research has examined youth experiences with and access to nature and benefits, little has been done in Canada, and few studies have used surveys and mixed-methods approaches. The purpose is to examine NS youth's experiences with and access to nature, and benefits to wellbeing.

Methods: The Nova Scotia Youth, Nature, and Wellbeing survey was created for NS youth aged 13-18 years, informed through literature reviews and youth focus groups, and is the first survey of its kind in Canada. The survey is situated within our Outdoor Health project, community-engaged participatory research focused on developing an integrated, multi-sector approach to outdoor/nature-based recreation and mental health services to support youth wellbeing in NS. The online survey includes open and closed-ended questions to provide context on youth experiences with and access to nature and benefits. Demographic information (age, geographic area, cultural identity, gender) is collected; youth are also asked whether they identify as belonging to an equity-owed group. The survey was launched on October 9, 2025, and distributed via partners (practitioners, educators, and policymakers in parks and recreation, allied health, youth services, and community development), other youth-serving and youth-led organizations, social media, posters, word-of-mouth, and youth-focused events.

Results: A total of 92 youth have completed the survey (November 2025); the goal is 300 responses, representing 0.5% of NS youth aged 13-18 (comparative with previous NS youth health surveys). Quantitative findings (frequencies, proportions) will be integrated with open-ended responses through a convergent mixed-methods approach. Data will be explored across demographics to examine disparities in access to nature, including equity-owed groups.

Conclusion: Findings will contribute to our goal of reducing inequities experienced by NS youth in accessing health-promoting natural spaces.

II-P-J.06

Pilot and Evaluation of a Nutrition Education Program for Emerging Adults

S. Rogus¹, L.O. Ademu¹, K.M. Alfaro Hudak¹, S. Venkatesh², M. Laguros³, E.F. Racine¹

¹Texas A&M AgriLife Research and Extension Center at El Paso, Department of Nutrition, El Paso, United States, ²Texas A&M AgriLife Extension Service, Department of Nutrition, College Station, United States, ³Texas A&M AgriLife Extension Service, Department of Nutrition, Fort Worth, United States

Purpose: Emerging adulthood (18 to 25 years) is a period of life characterized by transitions that lead to increased autonomy. Long-term health behaviors are typically established in this stage of life, yet many emerging adults have low quality diets, experience weight gain, and lack cooking skills. This presents an opportunity for nutrition education to promote healthier food choices. Community-based programs like the Expanded Food and Nutrition Education Program (EFNEP) have not historically targeted emerging adults. Therefore, we developed Fuel to Thrive (F2T) by adapting an EFNEP adult nutrition program and piloted it at Texas A&M University. The 5-week program included weekly in-person classes (~1 hour) on nutrition basics, knife skills, reading food labels, budgeting, meal planning, and food safety. We present the preliminary results of an evaluation of the F2T program.

Methods: The program was piloted by the university health center in spring 2025, with plans to continue data collection through fall 2025 and spring 2026. We collected pre- and post-survey data at the beginning and end of the program, respectively. We calculated summary statistics of baseline participant demographic characteristics and health behaviors in the pre- and post-periods. We also conducted focus groups with participants and interviews with educators following the final class to better understand the relevance of the curriculum. Content analysis was employed and descriptive categories were created that summarize participant perceptions.

Results: Thirty-three students registered for at least one class and 11 registered for the full five-session series.

J. YOUNG ADULT

Attendance varied across classes and dropped off as the program progressed. Nineteen students completed both pre- and post-surveys. While the number of respondents limits our ability to detect significant changes, preliminary results suggest that participants improved health behaviors following completion of the program. Two focus groups (with 9 total participants) and interviews (with 4 educators) suggested that the program was relevant for emerging adults and provided suggestions for future programming to streamline delivery and reinforce learning.

Conclusion: Early findings from this evaluation suggest that the program is effective and can inform future program modifications. Next steps include implementing and evaluating the program within EFNEP and in other settings outside the university.

II-P-J.08

Normative Values for Hop Tests Used to Assess Knee Injury Risk in Adolescent Athletes

A. Rivera-Brown, Ph.D.¹, D. Acosta², K. Hernández², A. Pabón, DrPH¹

¹University of Puerto Rico, Medical Sciences Campus, Department of Physical Medicine, Rehabilitation, and Sports Medicine, San Juan, Puerto Rico, ²University of Puerto Rico, Rio Piedras Campus, Department of Graduate Studies, San Juan, Puerto Rico

Purpose: Low scores and asymmetries in hop tests are associated with an increased risk of knee injuries in young athletes. There are few reference values for hop tests in adolescent athletes, making comparisons by sport, gender, and age difficult. Our aim was to determine normative values for vertical hop (VH), single hop for distance (SH), crossover hop for distance (CH), and side-to-side hops in 30 s (SSH), and for the limb symmetry index (LSI), in uninjured adolescent athletes.

Methods: Subjects were 114 athletes (females= 59; males=55; age=16.3 ± 1.2 yrs) from 16 sports. For VH, SH, and CH, athletes executed three practice and three test trials with the dominant (D) and non-dominant (ND) leg. The highest scores were chosen for analysis. For SSH, they performed five practice hops, and one test trial. The LSI was calculated as: $ND/D \times 100$. A paired t-test was used to compare D and ND scores, an independent samples t-test was used to compare test scores and the LSI between sexes and age-groups, and percentiles (10th to 100th) were calculated for each sex.

Results: No significant differences ($P > 0.05$) were found in D vs ND for any of the tests. LSI ranged from 89% to 94%. Males scored 36%, 23%, 27%, and 52% higher than females for VH (17.5 ± 4.4 vs. 12.9 ± 2.3), SH (148.7 ± 23.6 vs. 120.5 ± 17.0), CH (501.9 ± 87.8 vs. 395.6 ± 61.3), and SSH (43.4 ± 12.4 vs. 28.6 ± 8.5), respectively, ($P < 0.05$). There was no difference ($P > 0.05$) in hop performance between the 14-15 and 16-18 year-old age groups. The 10th and 90th percentiles for females were: VH= 9.8 and 16.7 cm; SH=96 and 143 cm; CH=316 and 480 cm; and SSH=19 and 39.6 cm; and for males: VH=11.8 and 23.5 cm; SH=115 and 178.2 cm; CH=386.2 and 612 cm; and SSH=23.6 and 56.4 cm.

Conclusion: The mean and percentile values of uninjured adolescent athletes determined in this study are useful to assess knee injury risk by age and sex. These reference values may also help evaluate the progress of adolescent athletes during rehabilitation and return to sport following knee injuries.

II-P-J.09

Physical Activity Program Executed through Immersive Virtual Reality for the Improvement of Body Composition and Physical Condition

A. Godoy¹

¹Universidad Autónoma de Chile, Grupo de Investigación en Educación Física, Salud y Calidad de Vida (EFISAL), Facultad de Educación, Temuco, Chile

Purpose: The practice of physical activity is beneficial for health. However, a large part of the adult population does not comply with the recommendations for physical activity, due to factors such as lack of time and nearby sports facilities. Immersive virtual reality is a tool that allows people to immerse themselves in a simulated world and perceive visual, auditory, and tactile sensations. Its use in physical activity interventions favors exercise in situations that, due to time and space, could be limited in real life. The aim of this research is to measure the impact on body composition and physical fitness of an exercise program executed through immersive virtual reality.

Methods: Repeated measures study (pre-post, without control group), in which body composition (fat and muscle

J. YOUNG ADULT

component) and physical fitness (cardiorespiratory fitness, speed-agility and manual grip strength components) were evaluated. The physical exercise program based on immersive virtual reality lasted 14 weeks.

Results: The results indicate that the fat component decreased and the musculature slightly improved. For physical fitness, cardiorespiratory fitness and speed-agility improved, but manual grip strength decreased.

Conclusion: It is concluded that training developed through immersive virtual reality proves to be a tool that can promote improvements in body composition and physical fitness.

II-P-J.10

Force Manifestation-Specific Adaptations After a 4-week Trunk Resistance Training program in Adults with Non-specific Chronic Low Back Pain

P. Aragón Aragón¹, J. Castro Piñero¹, W. Reyes Ferrada², Á. Rodríguez Perea³

¹University of Cádiz, Puerto Real, Spain, ²University of Andres Bello, Santiago, Chile, ³University of León, León, Spain

Purpose: Non-specific chronic low back pain (NSCLBP) is a leading cause of disability worldwide, with significant impacts on individuals' physical well-being. Trunk resistance interventions are recommended for NSCLBP, yet the neuromuscular mechanisms underlying clinical improvement remain insufficiently understood. In particular, it is unclear whether different trunk force assessment devices capture distinct manifestations of force adaptations following resistance training and how these adaptations relate to pain reduction. This study aims to examine trunk force adaptations following a trunk resistance training (TRT) program using two complementary assessment devices and to explore associations between changes in trunk force and pain intensity in adults with NSCLBP.

Methods: 28 participants with NSCLBP were enrolled in a RCT and allocated to a TRT group or a control group. The intervention consisted of supervised TRT performed twice weekly for 4 weeks. Trunk force was assessed pre and post intervention using an isokinetic dynamometer and a functional electromechanical dynamometer (FEMD). Isokinetic assessment quantified flexors and extensors peak torque, total work, and average power per repetition, whereas FEMD assessed concentric and eccentric mean force. Pain intensity was measured using an 11-points NRS. Repeated measures mixed ANOVA analyses evaluated Time x Group interaction, and Pearson's bivariate correlation analyses explored associations between changes in force variables and pain intensity.

Results: Significant Time x Group interactions were observed for trunk extensor total work ($p=0.024$) and average power per repetition ($p=0.019$) assessed with the isokinetic device, indicating greater improvements in the TRT group. FEMD variables showed significant within-group increases in concentric and eccentric trunk extensor mean force but no significant interaction effects. Improvements in isokinetic trunk extensor work and power were moderately associated with reductions in pain intensity ($p<0.05$). Associations between FEMD-derived force changes and pain reduction were weaker and non-significant ($p>0.05$).

Conclusion: TRT induced force manifestation-specific adaptations, with notable improvements in repeated-force capacity and power using isokinetic assessment. Combining isokinetic and FEMD devices provided complementary insights, suggesting that different assessment methods may vary in sensitivity to early training-induced changes. These findings clarify the mechanical correlations of pain reduction and support multidimensional trunk force assessment in NSCLBP rehabilitation.

II-P-J.11

Physical Activity-related Health Competence beyond 24-hour Movement Behaviours in Explaining Life Satisfaction among Central European University Students

A. Makai^{1,2}, F. Salonna³, J. Baj-Korpak⁴, M.J. Stelmach⁴, L. Šedová⁵, V. Prémusz^{1,2}, P. Ács^{1,2}

¹University of Pécs, Faculty of Health Sciences, Pécs, Hungary, ²Szentágothai Research Centre, University of Pécs, Physical Activity Research Group, Pécs, Hungary, ³Pavol Jozef Šafárik University, Institute of Physical Education and Sports, Košice, Slovakia, ⁴John Paul II University in Biala Podlaska, Department of Health Sciences, Biala Podlaska, Poland, ⁵University of South Bohemia in České Budějovice, Faculty of Health and Social Sciences, České Budějovice, Czech Republic

Purpose: The 24-hour movement behaviour (24HMB) framework conceptualizes moderate-to-vigorous physical activity (MVPA), sedentary behaviour, and sleep as integrated components of daily health. Physical activity-related health competence (PAHCO) reflects individuals' capacity to manage and regulate physical activity in health-

promoting ways. This study examined whether PAHCO explains additional variance in life satisfaction beyond 24HMB among Central European university students.

Methods: Cross-sectional data were analysed from 2,691 university students aged 18–29 years from the V4 countries participating in the V4MoRe project. MVPA and daily sitting time were assessed using the International Physical Activity Questionnaire (IPAQ–Long Form), and average sleep duration was self-reported. PAHCO was assessed using movement, control, and self-regulation competence dimensions. Life satisfaction was measured using a single-item 10-point ladder. Hierarchical linear regression analyses were conducted. Model 1 included MVPA, sitting time, sleep duration, gender, and country. Model 2 additionally included the three PAHCO dimensions. Standardized coefficients (β) and explained variance (R^2) were examined using IBM SPSS version 29.0.

Results: Participants had a mean age of 21.31 years ($SD = 2.34$); 72.1% were female, and mean life satisfaction was 6.72 ($SD = 1.62$). In Model 1, MVPA ($\beta = .100, p < .001$), sitting time ($\beta = -.093, p < .001$), and sleep duration ($\beta = .052, p = .015$) were significantly associated with life satisfaction, explaining 3.0% of variance ($R^2 = .030$) adjusted for gender and country. After inclusion of PAHCO dimensions (Model 2), explained variance increased to 10.4% ($R^2 = .104$). Movement competence ($\beta = .131, p < .001$), control competence ($\beta = .101, p < .001$), and self-regulation competence ($\beta = .105, p < .001$) were significant positive predictors.

Conclusion: PAHCO explained substantially more variance in life satisfaction than 24HMB alone and reduced the strength of behavioural associations. These findings highlight the importance of competence-related psychological factors in understanding links between daily movement patterns and subjective well-being. Integrating competence development into 24-hour movement strategies may strengthen their impact in young adult populations. The research was funded by the V4More project co-financed by the International Visegrad Fund under the Visegrad Grants programme (Agreement number 22420149).

II-P-J.12

Examining Identity and Habit as Predictors of Device-measured Physical Activity Trajectories During the First Semester of College

C. Holesovsky¹, C. Johnston¹, D. Brown¹

¹Kansas State University, Manhattan, United States

Purpose: Although many first-year students arrive at college engaging in levels of physical activity (PA) that meet public health guidelines, maintaining these patterns is challenging, and substantial declines commonly emerge during the first semester. The Multi-Process Action Control framework proposes that reflexive processes (i.e., habit, identity) support sustained PA. However, few studies have examined whether these processes predict trajectories of device-measured PA. This study tested whether habit and identity predict trajectories of weekly PA across the first semester of college.

Methods: Secondary data were drawn from the College Activity and Mental Health (CALM) study, a prospective cohort of 144 first-year undergraduate students assessing movement behaviors and mental health during the college transition. A total of 118 students ($Mean = 18 \pm 0.3$ years; 58% female) with <30% missing moderate-to-vigorous PA (MVPA) were included in the analytic sample. MVPA was continuously assessed for 16 weeks using Fitbit Charge 6 devices and aggregated into weekly minutes. PA-related habit (Self-Report Behavioral Automaticity Index) and identity (Exercise Identity Scale) were assessed at baseline. Latent growth curve models estimated trajectories of MVPA and tested whether habit and identity predicted baseline levels (intercept) and rates of change (slope), adjusting for sex. Sensitivity analyses examined moderate and vigorous PA separately.

Results: Significant declines in weekly MVPA were observed ($b = -12.21, p = .002$), driven by declines in moderate PA ($b = -9.76, p < .001$), but not vigorous PA ($b = -2.74, p = .46$). Identity predicted higher baseline MVPA ($b = 43.24, p = .014$) and moderate PA ($b = 19.42, p = .016$), but did not consistently predict change over time, except for steeper declines in moderate PA ($b = -1.01, p = .040$). Habit was not significant in any models. Strong negative intercept–slope covariances ($rs \approx -.80$) indicated that students with higher initial MVPA experienced larger declines.

Conclusion: Although identity predicted higher initial PA levels, neither identity nor habit buffered declines in PA during the first semester. These findings suggest that reflexive processes alone may be insufficient to sustain PA amid the contextual disruptions of the college transition. Future research should examine dynamic contextual factors that undermine PA maintenance during this critical period.

J. YOUNG ADULT

II-P-J.13

Understanding Mechanism of Physical Activity Maintenance During the Transition to College: An Intensive Longitudinal Examination of Stress and Reflexive Processes

C. Holesovsky¹, C. Johnston¹, A. Rebar², M. Kwan^{3,4}, D. Caragea¹, J.M.S. Hutchinson¹, R. Rhodes⁵, D. Brown¹

¹Kansas State University, Manhattan, United States, ²University of South Carolina, Columbia, United States, ³Brock University, St. Catharines, Canada, ⁴McMaster University, Hamilton, Canada, ⁵University of Victoria, Victoria, Canada

Purpose: Reflexive processes (i.e., habit, identity) are thought to sustain physical activity (PA) behavior, but prior longitudinal studies with infrequent assessments miss daily fluctuations in context, demands, and motivation, leaving the protective role of these stable processes unclear. The purpose of this study is to test whether reflexive processes moderate the effects of daily contextual factors (i.e., stress) on PA maintenance during the transition to college.

Methods: The Active College Transition: Investigating Activity, Trends, & Environment (ACTIVATE) study is a 16-week prospective cohort study of 85 first-year students (Mage=18±0.2yrs; 88% female) entering college in Fall 2025 who met aerobic PA guidelines and intentioned to maintain adherence. Daily PA (i.e., steps, active minutes) was collected via Apple Watch. Five monthly surveys assessed reflexive (i.e., habit, identity) processes outlined in the Multi-Process Action Control framework. Five randomly distributed 7-day diary bursts captured daily stress. Daily stress and PA were aggregated into weekly values. Linear mixed-effects models (weeks nested within persons) will be used to predict weekly PA from time, weekly stress, monthly habit and identity, stress*habit, stress*identity, and covariates (sex, BMI).

Results: Protocol compliance was high: 89.4% monthly survey completion, 75.1% daily survey completion, and 88.7% valid device days (>1,000 steps). Of the 85 enrolled participants, 73 provided ≥70% valid device wear data and will comprise the analytic sample. Linear mixed-effects model results will be presented to estimate within- and between-person effects on weekly PA trajectories and to examine whether habit and identity moderate the effects of stress on PA.

Conclusion: High-resolution, multimodal data are needed to elucidate the dynamic processes that foster or undermine PA maintenance. These theory-driven models represent an initial step toward integrating additional contextual indicators captured in ACTIVATE (e.g., daily PA intentions, mood, sleep quality, academic/social/occupational demands, campus recreation center use, and weather) using machine learning to detect individualized risk for PA disruption. Our work aims to identify when, where, and for whom disruption risk is elevated to inform just-in-time adaptive interventions. By moving beyond static predictors toward dynamic, precision-based models, this work advances our understanding PA maintenance.

II-P-J.14

Adolescent Perspectives on Participation in Research Using Device-based Sleep Measurement

A.F. Oxenham¹, B. Ram¹, A. Sharma², L. Cheng¹, E. Winpenny¹

¹Imperial College London, School of Public Health, London, United Kingdom, ²University of Oxford, Oxford, United Kingdom

Purpose: During adolescence, biological shifts in circadian timing, combined with social and academic pressures and frequent digital technology use, contribute to widespread sleep problems in young people. Recent advances in consumer sleep-tracking technology offer new opportunities to measure sleep objectively at scale, to inform research aiming to improve sleep health. However, optimal methods for collecting high-quality device-measured sleep data among adolescents in free-living settings remain unclear. This study aimed to explore adolescents' preferences for sleep monitoring and co-produce strategies to maximise participation in sleep research.

Methods: Our research was conducted in the UK and comprised of (1) online focus groups with 16–24-year-olds who had previously worn a FitBit as part of the Study of Cognition, Adolescents and Mobile Phones (SCAMP) in London, and (2) a series of six co-design workshops with Year 12 students (age 16–17) in Cambridge. The focus groups followed structured topic guides with 2–5 participants per group. Workshop participants tested four sleep-monitoring devices (Garmin Venu SQ, Fitbit Inspire 3, Withings Sleep Analyzer, and GeneActiv) and provided structured feedback. Framework analysis was applied to transcripts to identify themes relating to motivations and barriers to participation, preferences for sleep monitoring, and inform strategies to optimise participation and retention in future studies.

Results: 20 young people took part in the focus groups and 28 participated in the workshops. Participants agreed

J. YOUNG ADULT

that interest in sleep and health data were a key driver of participation, as well as financial incentives and interest in using a tracking device. Trust in researchers and transparency around data use were important when considering participation. Barriers to engagement included device discomfort, particularly sleep disturbances during overnight wear, technical issues, and forgetting to wear devices. Reactions to seeing their own health data varied, with some reporting increased awareness and behaviour change, while others had negative affective responses. Participants noted that meaningful feedback and seeing study outputs were important to them.

Conclusion: Sleep monitoring in adolescents is feasible but contingent on trust, perceived value, and low device burden. Aligning current technology potential with adolescent preferences is important achieving high-quality, scalable sleep measurement and advancing understanding of sleep as a determinant of health.

II-P-J.15

Acute Resistance Exercise Load Modulates Brain Hemodynamics, Working Memory, and Inhibitory Performance

R. Martins¹, S. Ludyga², M. Hanke², F. Herold³, M. Crotti⁴, V. Looser², M. Hill⁵, M. Duncan⁶

¹University of Alberta, Edmonton, Canada, ²Universität Basel, Basel, Switzerland, ³Health and Medical University Erfurt, Erfurt, Germany, ⁴University of Bergamo, Bergamo, Italy, ⁵University of Leicester, Leicester, United Kingdom, ⁶Coventry University, Coventry, United Kingdom

Purpose: Acute resistance exercise can transiently enhance executive function, but the extent to which exercise load influences specific executive domains and the underlying neurophysiological mechanisms remain unclear. This study compared the immediate and delayed effects of moderate versus high load resistance exercise on inhibitory control, working memory, and prefrontal cortex hemodynamics measured with functional near infrared spectroscopy (fNIRS).

Methods: Forty-two healthy, physically active adults (mean age 26.9 years; 24 men) were randomly allocated to high load resistance exercise (HRE, 75% of estimated one repetition maximum, 3 sets of 8 repetitions), moderate load resistance exercise (MRE, 50%, 3 sets of 12 repetitions), or a seated control condition (CON). Workload was equated across exercise groups by adjusting load and repetitions. Executive function was assessed pre-exercise, 5 to 10 minutes post exercise, and 45 minutes post exercise using a Stroop task (congruent and incongruent trials) and an n back task (1 back and 2 back). During cognitive testing, multi channel fNIRS measured oxygenated haemoglobin (O2Hb) responses over left and right dorsolateral prefrontal cortex.

Results: HRE produced small improvements in Stroop incongruent reaction time (d 0.40) and moderate to large improvements on the 2-back task (d 0.80 post; d 0.93 post45), exceeding changes in MRE (approximately d 0.60) and CON (approximately d 0.30 to 0.45). HRE elicited stronger right lateralised increases in prefrontal oxygenation, including congruent Stroop right hemisphere O2Hb increases (post d approximately 0.65). MRE showed smaller O2Hb increases (d 0.35 to 0.54), while CON showed minimal or declining activation.

Conclusion: High load resistance exercise showed the most consistent improvements in executive function, particularly under higher cognitive demand, and was accompanied by increased right lateralised prefrontal oxygenation. These findings suggest that resistance exercise load is an important determinant of acute cognitive and neurophysiological responses, with potential implications for optimising exercise prescriptions to support cognitive functioning.

II-P-J.16

Relationship between Muscle Mechanical Properties and Perceived Spasticity in People with Multiple Sclerosis: Data from ADVICE Project

L. González-Mingorance¹, R. Cupeiro², L. Andreu-Caravaca³, S. Villena-Molina¹, V. Ávila-Gandía³, J.Á. Rubio-Arias¹, M.d.C. Ferrer-Contreras¹

¹Universidad de Almería, Health Research Centre, Hum-628 Research Group, Department of Education, Almería, Spain, ²Universidad Politécnica de Madrid, LFE Research Group, Department of Health and Human Performance, Faculty of Physical Activity and Sport Science (INEF), Madrid, Spain, ³Universidad Católica San Antonio de Murcia, Sports Physiology Department, Faculty of Health Sciences, Murcia, Spain

Purpose: In people with multiple sclerosis (MS), spasticity impacts wellbeing and functional status, limiting participation in exercise. Although its assessment is usually based on subjective reports or clinical measures, identifying whether objective muscle mechanical properties are associated with self-reported spasticity could

J. YOUNG ADULT

contribute to a more comprehensive assessment of this symptom. Therefore, this study examined the association between muscle mechanical properties assessed with MyotonPRO and self-reported spasticity in people with MS.

Methods: Twenty adults with MS (10 men, 10 women) were recruited from the Multiple Sclerosis Unit of Virgen de la Arrixaca Hospital (Murcia, Spain). Self-perceived spasticity was quantified using the Numerical Rating Scale (NRS). Bilateral assessment of muscle mechanical properties was performed with MyotonPRO at the vastus lateralis (VL), rectus femoris (RF), vastus medialis (VM), lateral gastrocnemius (LG), medial gastrocnemius (MG), and Achilles tendon (AT). Frequency, stiffness, decrement, relaxation time, and creep were recorded. Associations between NRS scores and Myoton-derived variables were examined using Spearman's rank correlation coefficients. Correlations were classified as small (0.10–0.29), moderate (0.30–0.49), or large (≥ 0.50), with statistical significance set at $p < 0.05$.

Results: Higher NRS scores showed a moderate positive correlation with frequency in the right RF ($r = 0.473$, $p = 0.035$). Conversely, in the right LG, higher NRS scores tended to correlate with lower frequency ($r = -0.415$, $p = 0.069$), lower stiffness ($r = -0.435$, $p = 0.055$), and higher relaxation time ($r = 0.381$, $p = 0.097$). Similar pattern was observed in the right AT between NRS scores and frequency ($r = -0.491$, $p = 0.028$), stiffness ($r = -0.328$, $p = 0.159$), and relaxation time ($r = 0.348$, $p = 0.132$). The left LG demonstrated a similar trend.

Conclusion: Associations between self-reported spasticity and muscle mechanical properties were site-specific. Greater spasticity was associated with higher frequency in the right RF, whereas calf muscles and the AT showed reduced frequency and stiffness alongside prolonged relaxation time. These findings suggest distinct mechanical responses between quadriceps and triceps surae–tendon structures in MS. Myoton-based assessment may help characterize spasticity-related impairments relevant to physical function, improving exercise prescription in this population.

II-P-J.17

Gen Z's Perceptions of Stress, Digital Environments, and Weight Management Behaviors: Findings from Project EAT Next Generation Focus Group Discussions

K. Johnson¹, V. Píram¹, N. Larson², D. Neumark-Sztainer¹

¹University of Minnesota, Epidemiology and Community Health, Minneapolis, United States, ²Texas Tech University, Nutritional Sciences, Lubbock, United States

Purpose: The socio-environmental landscape for young people has shifted drastically since Project EAT (Eating and Activity over Time) began in the late 1990s. Gen Z (born 1997–2012) navigates a nexus of a global pandemic, economic challenges, and an image-centric digital ecosystem (e.g., TikTok, Instagram). While body-positive messaging is more popular, it coexists with proliferating digital weight-management tools and new pharmacotherapies. This work represents the first step of a larger study exploring contemporary stressors and technological shifts and their potential relevance for eating, activity, and weight-related health of Gen Z young people.

Methods: We conducted six virtual focus group discussions: three with adolescents (ages 13–17; $n = 31$) and three with young adults (ages 18–25; $n = 27$) from across the U.S. Semi-structured guides explored stress, social media, and weight-management behaviors, including familiarity with GLP-1 medications. Questions were refined with our young adult community advisory board to ensure relevance and comprehension. Initial thematic analysis was conducted independently by two researchers and refined through consultation with community advisory boards and the full research team. Formal qualitative analyses are planned and will be shared at the conference.

Results: Participants reported academic pressure, social relationships, and future uncertainty as primary stressors. Coping strategies included both active behaviors (e.g., focusing on homework, exercise) and avoidant behaviors (e.g., sleep, scrolling social media). Preliminary themes suggest that stress may disrupt eating patterns; adolescents frequently reported meal skipping due to perceived time scarcity, while young adults reported a mix of restriction and emotional eating. Despite awareness of wellness practices like yoga and meditation, engagement appeared low, potentially due to a lack of guidance or perceived personal inefficacy. While participants demonstrated awareness of social media risks (e.g., “doom scrolling”) and benefits (e.g., learning, connection), niche “pro-disorder” content (e.g., “eating disorder Twitter”) remains a potential underlying risk. Preliminary analysis also highlighted stigma against weight-loss medications, which were dismissed as an “easy way out.”

Conclusion: These findings are being utilized to inform our survey development in which a U.S. national sample of 2500 young people will provide data on the broad spectrum of eating, activity, and weight-related health.

II-P-J.18

Demystifying the “Freshman 15” with Comprehensive and Repeated Physical Assessments of First-year College Students in North Carolina

A.A. Dahl¹, R. Paul¹, S. Fandetti², E.F. Racine²

¹University of North Carolina at Charlotte, Epidemiology and Community Health, Charlotte, United States, ²Texas A&M AgriLife Research Center at El Paso, El Paso, United States

Purpose: The transition to college is a major milestone for emerging adults. First-year college students living on campus experience autonomy in health decision-making and establish behavioral patterns that can be carried into adulthood. Public health data indicates obesity, diabetes, and other chronic conditions are on the rise among 18-24 year olds living in the United States. The purpose of this study was to explore changes in students' physiological health outcomes across their first academic year while attending a public university in North Carolina. We hypothesized there would be less favorable health outcomes related to the development of chronic conditions observed by the end of the spring semester.

Methods: Participants were first-year students recruited through university email announcements and fliers. There were two lab-based measurement visits, one per semester scheduled at least six months apart, conducted at the Health Risk Assessment Lab on campus. At each visit, participants completed an online survey of demographics, health history, and self-reported health behaviors. Students were also asked to provide consent for access to University card swipe data which linked the research team to meal plan usage, decline cash balances on food and beverage purchases, and recreational facility usage. After the survey, participants completed anthropometric measurements (e.g., DEXA scan), and physical assessments including blood pressure and a blood draw by finger stick (e.g. triglycerides, A1c, cholesterol). Individual student data were linked between visits and two-sided t-tests and correlations were conducted.

Results: Ninety participants completed their baseline assessment, with 73 returning for the follow-up. In less than 9 months, we observed a significant raise in A1c (T1=4.5, T2=4.6, p=0.036), as with diastolic blood pressure (T1=69, T2=71, p=0.003) and visceral fat (T=0.5, T2=0.6, p=0.027). Triglycerides decreased significantly.

Conclusion: We observed small effect sizes which were expected due to our sample size and limited time frame. However, these findings suggest additional longitudinal studies on physiological changes during college years would be valuable. Our results indicate college students are at an increased risk for developing long-term chronic conditions, underlining the importance of health promotion interventions.

Timing of Device-measured Physical Activity and Sleep in Relation to Meeting Physical Activity Guidelines in U.S. Adults

K. Zhang^{1,2}, J.J. Lang^{3,4}, J.-P. Chaput^{1,5}

¹Healthy Active Living and Obesity Research Group, Children's Hospital of Eastern Ontario Research Institute, Ottawa, Canada, ²University of Ottawa, School of Human Kinetics, Ottawa, Canada, ³Centre for Surveillance and Applied Research, Public Health Agency of Canada, Ottawa, Canada, ⁴University of Ottawa, School of Epidemiology and Public Health, Faculty of Medicine, Ottawa, Canada, ⁵University of Ottawa, Department of Pediatrics, Ottawa, Canada

Purpose: This cross-sectional study aimed to provide the first nationally representative evidence on whether the timing of daily moderate-to-vigorous physical activity (MVPA) and sleep is independently and jointly associated with adherence to physical activity (PA) guidelines among U.S. adults.

Methods: We analyzed data from the 2003–2006 National Health and Nutrition Examination Survey (NHANES). Eligible participants were non-pregnant adults aged ≥ 20 years with valid accelerometer data and ≥ 5 min/day MVPA. We excluded individuals with extreme MVPA (>200 min/day), mobility limitations, or missing covariates. Participants ($n=3,153$) were categorized into morning (6:00–9:59), midday (10:00–13:59), afternoon (14:00–17:59), evening (18:00–21:59), or overnight (22:00–5:59) if $\geq 50\%$ of their average daily MVPA occurred in that window; those not meeting this threshold were assigned to a mixed group. Sleep periods were estimated from daily non-wear accelerometer intervals of 4–14 h. Participants with valid estimated sleep data ($n=2,370$) were categorized as irregular if the standard deviation (SD) of sleep midpoint was >1 h; regular sleepers ($SD \leq 1$ h) were further classified by mean sleep midpoint: early (22:00–01:59), mid (02:00–03:59), late (04:00–07:59). Meeting PA guidelines was defined as an equivalent combination of moderate- and vigorous-intensity PA ≥ 150 min/week. Because outcome prevalence exceeded 40%, we used survey-weighted modified Poisson regression with robust variance to estimate prevalence ratios (PRs) and 95% confidence intervals (CIs), adjusting for sociodemographic, behavioural, and health covariates. Joint associations were examined in the sleep subsample.

Results: Morning MVPA ($PR=1.48$, $95\%CI=1.31-1.66$) and early sleep timing ($PR=1.14$, $95\%CI=1.01-1.28$) were each independently associated with a higher prevalence of meeting PA guidelines compared to the mixed MVPA and irregular sleep timing group, respectively. These associations were stronger in morning MVPA with early sleep ($PR=1.69$, $95\%CI=1.22-2.34$) and morning MVPA with mid sleep ($PR=1.70$, $95\%CI=1.45-1.99$), and were also significant in midday MVPA with mid sleep ($PR=1.48$, $95\%CI=1.23-1.78$), compared to the mixed MVPA with irregular sleep group.

Conclusion: The associations between morning MVPA, earlier sleep and higher PA guideline adherence may inform the development of timing-based strategies for MVPA and sleep in PA promotion, while prospective studies are needed to validate these associations and evaluate their effectiveness.

I-P-K.03

A 12-week School-based Exergaming Intervention to Promote Physical Activity in Preschool Children: A Randomized Controlled Trial

N. Zeng¹

¹University of Massachusetts Boston, Exercise and Health Sciences, Boston, United States

Purpose: The early years of life are critical for developing healthy movement behaviors linked to optimal physical, cognitive, and emotional growth. Integrating exergaming into preschool curricula represents an innovative strategy to enhance physical activity engagement in young children. This study aimed to evaluate the efficacy of a 12-week school-based exergaming intervention in promoting physical activity among preschoolers.

Methods: This randomized controlled trial included 56 preschool children (mean age = 4.56 ± 0.78 years; 30 girls) randomly assigned to an intervention group ($n = 28$) or a control group ($n = 28$). The intervention group participated in structured exergaming sessions 5 days per week for 25–30 minutes each session, while the control group continued their regular classroom routine. Physical activity was assessed using accelerometers at baseline and post-intervention, focusing on school-time moderate-to-vigorous physical activity (MVPA). Data were analyzed using linear mixed-effects models, accounting for repeated measures and group-by-time interactions, with significance set at $p < 0.05$.

Results: The intervention significantly increased school-time MVPA compared with the control group. Children in the intervention group showed an average increase of 15 minutes per day ($95\%CI: 10-20$ minutes; $p < 0.01$; $d = 0.80$), whereas the control group increased by 3 minutes ($95\%CI: 1-5$ minutes; $p < 0.01$; $d = 0.20$). Subgroup analysis

K. PARTICIPATORY RESEARCH IN HEALTH PROMOTION

indicated that children with baseline MVPA < 20 minutes per day exhibited the largest gains (+18 minutes; 95% CI: 12–24 minutes; $p = 0.02$; $d = 0.90$). Attendance averaged 92%, indicating strong adherence and feasibility.

Conclusion: This 12-week school-based exergaming intervention effectively increased physical activity among preschool children, demonstrating a feasible and engaging approach to promoting movement in early childhood. The high participation rate underscores its acceptability within preschool settings. Exergaming holds promise as a scalable strategy for educators and policymakers to integrate enjoyable, evidence-based physical activity into early learning environments, supporting the establishment of lifelong healthy movement habits.

I-P-K.04

Changes in Knowledge and Engagement of a Participatory Systems Approach to Promote Health among Social Health and Care Vocational Students: A Single-arm, Double-sited Feasibility Study

L. Olesen¹, A. Sidenius², H. Kirkegaard¹, C.D. Klinker^{2,3}, J.N. Østergaard^{1,3}

¹Aarhus University Hospital, Steno Diabetes Center Aarhus, Aarhus, Denmark, ²Copenhagen University Hospital, Steno Diabetes Centre Copenhagen, Herlev, Denmark, ³University of Southern Denmark, National Institute of Public Health, Copenhagen, Denmark

Purpose: Participatory systems-based community-interventions applying group model building (GMB) show promise in addressing childhood obesity. This study explores the impact of a GMB-process on changes in stakeholders' knowledge and engagement in a social health and care vocational school setting. It also explores whether knowledge and engagement after the final GMB workshop are associated with subsequent action implementation.

Methods: This feasibility study (PROVE IT, Denmark) assessed composite normalization scores (0-1) for knowledge and engagement among school-, municipality- and internship staff and management at three time points at two sites: before workshop 1, immediately after the final GMB workshop and 9 months later, using an adapted version of the COMPACT Stakeholder-driven Community Diffusion survey. Additionally, actions implemented within the year following the final GMB workshop were recorded. Mixed-effects regression analyses explored the impact of the GMB workshop process on knowledge and engagement relative to baseline with work position and workshop participation as fixed effect, and site and stakeholder id as random effects. In a subgroup analysis with additional adjustment for baseline values it was explored if knowledge and engagement after the final GMB workshop were associated with subsequent action implementation.

Results: The analytic sample was 43 (98 %) at baseline, 23 (42 %) at first and 15 (29 %) at second follow-up, with attrition and loss to follow-up evenly distributed across sites. Compared to baseline, improvements in knowledge (0.09 (95% CI: 0.04 to 0.14)) and engagement (0.06 (95% CI: 0.01 to 0.11)) after the final GMB workshop were statistically significant. Only knowledge (0.10 (95% CI: 0.04 to 0.14)) remained statistically significant 9-months later. In the subgroup analysis ($n=19$) knowledge and engagement of stakeholders were positively associated with the number of actions they contributed to implementing. However, giving the small sample size, this finding might reflect a type 1 error rather than an effect.

Conclusion: Tracking knowledge and engagement provides valuable insights into outcomes of the GMB process, though the high dropout rates may affect the interpretation of the results. Limited tools exist to measure effects of GMB processes, emphasizing the need for further validation and testing in larger-scale studies.

I-P-K.05

Effects of Undulating Versus Traditional Resistance Training on Total and Pelvic Bone Mineral Density and Content in Postmenopausal Women: A Pilot Study

R. Fernandez Cabello¹, S. Vargas Molina¹, J. Luis Petro², J. Benitez Porres¹

¹Universidad de Málaga, Málaga, Spain, ²Universidad de Córdoba, Colombia, Colombia

Purpose: This pilot study compared the effects of traditional and daily undulating Resistance training on whole-body and pelvic bone mineral density (BMD) and bone mineral content (BMC) in postmenopausal women.

Methods: Eight postmenopausal women were allocated to traditional training (TT; $n = 4$; age 64.8+2.6 years; BMI

K. PARTICIPATORY RESEARCH IN HEALTH PROMOTION

25.3±1.7 kg/m²) or undulating training (UT; n = 4; age 62.8±2.9 years; BMI 25.2±2.2 kg/m²). TT performed three sets of 8-10 RM with 2-3 repetitions in reserve and 1.5 min rest intervals. UT followed a daily undulating model across weekly sessions: 35 RM (3 min rest), 8-10 RM (1.5 min rest), and 20 RM (45 s rest). All exercises were performed with maximal intended concentric velocity and identical exercise selection. Whole-body and pelvic BMD and BMC were assessed by DXA; the coefficient of variation was <1.5%, and calibration was performed daily according to manufacturer guidelines. Analyses followed an estimation-statistics approach with 95% confidence intervals.

Results: Mean pre-post change scores (A = Post-Pre) were small outcomes. For whole-body BMC, A was 39.4g in TT and 14.6g in UT, yielding a between-group difference in change(ATT-AUT) of 24.8g (95% CI: -112.6 to 162.1). For whole-body BMD, ATT - AUT was 0.00g/cm² (95% CI: -0.03); for pelvic outcomes, ATT-AUT was 6.8g for Pelv-BMC (95% CI: -8.8 to 22.3) and -0.04 g/cm² for Pelv-BMD (95% CI: -0.10 to 0.03). Across all outcomes, the 95% confidence intervals included the null, so the data do not allow firm inferences about between-group differences.

Conclusion: In this small pilot sample of postmenopausal women, TT and UT produced trivial-to-small changes in whole-body and pelvic BMC/BMD. Between-group differences in change were uncertain, with confidence intervals consistent with effects in either direction. These pilot findings justify larger, adequately powered trials to refine the estimates and clarify whether periodization model meaningfully influences pelvic bone outcomes.

I-P-K.06

Associations between Cardiorespiratory Fitness and Liver Fat in Children: The MICROKID Project

M. Herrada-Robles¹, M. Osés^{2,3}, V.M. Alfaro-Magallanes^{2,3,4}, C. Cadenas-Sanchez^{1,5}, I. Labayen^{2,3,5}

¹PROFITH „PRoMoting FITness and Health through Physical Activity“ Research Group, Sport and Health University Research Institute (iMUDS), Department of Physical Education and Sports, Faculty of Sport Sciences, University of Granada, Granada, Spain, ²Institute for Sustainability & Food Chain Innovation (IS-FOOD), Department of Health Sciences, Public University of Navarre, Pamplona, Spain, ³IdiSNA, Navarra Institute for Health Research, Pamplona, Spain, ⁴Department of Health and Human Performance, Faculty of Physical Activity and Sport Sciences, LFE Research Group, Universidad Politécnica de Madrid, Madrid, Spain, ⁵CIBER de Fisiopatología de la Obesidad y Nutrición (CIBEROBN), Instituto de Salud Carlos III, Granada, Spain

Purpose: Cardiorespiratory fitness is a key marker of pediatric metabolic health and may be inversely related to ectopic liver fat. This question is clinically salient given the growing burden of pediatric overweight/obesity. Robust evidence in children is limited, as many studies rely on indirect adiposity measures and insufficient adjustment for confounders. Therefore, the aim of this study was to examine the association between cardiorespiratory fitness and liver fat percentage in children from the MICROKID study.

Methods: A cross-sectional analysis of 60 children (25 girls; mean age 11.19 ± 1.75 years) from the MICROKID study was conducted. Cardiorespiratory fitness was assessed using the 20-m shuttle run test (laps). Liver fat percentage was quantified as MRI-derived proton density fat fraction (PDFF) during breath-hold. Descriptive statistics were stratified by sex. Associations were examined with Spearman's correlation and linear regression of log-transformed liver fat (%) as the dependent variable. Model 1 adjusted for age and sex; Model 2 additionally adjusted for BMI. Results are presented as percent differences in liver fat per 1-SD higher cardiorespiratory fitness.

Results: Median liver fat was 3.50% [3.00–4.20] in girls and 4.50% [3.40–7.57] in boys. Cardiorespiratory fitness correlated inversely with liver fat (Spearman $\rho = -0.56$; $p < 0.001$). In Model 1, each +1 SD higher fitness was associated with -20.8% liver fat (95% CI -31.3 to -8.8; $p = 0.002$). In Model 2, the association attenuated and was not significant (+9.6%; 95% CI -11.5 to 35.6; $p = 0.393$). Boys had higher liver fat than girls independent of covariates (51% relative difference; $p = 0.001$). BMI was positively associated with liver fat (9.7% per 1 kg/m²; $p < 0.001$), whereas age was not.

Conclusion: Higher cardiorespiratory fitness is associated with lower hepatic fat in school-age children. However, this inverse association is largely attenuated after accounting for BMI, suggesting that overall adiposity explains a substantial proportion of the fitness liver fat relationship. These findings support early-life strategies that jointly enhance fitness and address adiposity to mitigate pediatric ectopic fat accumulation and future metabolic risk.

I-P-K.07

Association between Meal Timing and the Risk of Metabolic Syndrome among Korean Adults: A Cross-sectional Data from the Korea National Health and Nutrition Examination Survey

J. Hwang¹, W. Khaing¹, S. Shin¹

¹Chung-Ang University, Food Science and Nutrition, Anseong-si, Gyeonggi-do, Korea, Republic of

Purpose: Metabolic syndrome (MetS) is a cluster of metabolic risk factors, including obesity, hypertension, diabetes, and dyslipidemia, that arise from abnormalities in the body's metabolic processes. Previous studies have focused on aspects of chrono-nutrition such as meal frequency and fasting duration, **but** research on specific meal timing remains limited in Korea. Therefore, this study aimed to investigate the association between meal timing and MetS in Korean adults.

Methods: This study analyzed data from 47,346 participants aged 40–69 years from the Korea National Health and Nutrition Examination Survey (KNHANES, 2010–2023), excluding those without data on meal timing or MetS, those with abnormal energy intake, or those with extreme body mass index (BMI) values. Meal timing was categorized into four groups based on breakfast and dinner time intervals. In addition, a combined meal-timing pattern was constructed using both breakfast and dinner timing to evaluate differences according to meal-timing patterns (Early–Early, Early–Late, Late–Early, and Late–Late). Logistic regression analyses were conducted to examine the association between meal timing and MetS. Model 1 was adjusted for age, while Model 2 additionally included education level, smoking status, alcohol consumption, physical activity, BMI, total energy intake, and household income.

Results: The analysis revealed that a later breakfast time was associated with higher odds ratios (ORs) of MetS in both sexes (men: 1.22, 95% CI: 1.07–1.38; women: 1.49, 95% CI: 1.18–1.66). In addition, a later dinner time was associated with an increased prevalence of MetS only in women, with an OR of 1.22 (95% CI: 1.08–1.38). When considering combined meal-timing patterns, the Late–Late pattern showed the highest risk of MetS (OR 1.57, 95% CI: 1.33–1.85).

Conclusion: This study demonstrated that specific meal timing habits are independently associated with an increased risk of MetS among Korean adults. These findings suggest that the timing of meals may play a crucial role in metabolic health and highlight the importance of incorporating chrono-nutritional perspectives into dietary guidelines and public health strategies.

Sit Less or Be Fittest? Sedentary Time, Patterns, and Cardiovascular Health in Apparently Healthy Adults: The Moderating Role of Physical Fitness

R. Martins^{1,2}, J. Castro-Piñero^{2,3}, R. Pinto⁴, S. Sánchez-Parente^{2,3}, C. Cruz-León^{2,3}, A. Perez-Bey^{2,3}, J. Cies-Valleras^{2,3}, M. Cuenca-García^{2,3}

¹Polytechnic University of Beja, Department of Arts, Humanities and Sport, Beja, Portugal, ²GALENO Research Group, Department of Physical Education, Faculty of Education Sciences, University of Cadiz, Puerto Real, Cádiz, Spain, ³Instituto de Investigación e Innovación Biomédica de Cádiz (INIBICA), Cadiz, Spain, ⁴Exercise and Cardiovascular Rehabilitation Laboratory, Centro Cardiovascular da Universidade de Lisboa (CCUL@RISE), Faculdade de Medicina, Universidade de Lisboa, Lisboa, Portugal

Purpose: Sedentary behaviour (SB) is a recognised cardiovascular risk factor, yet no consensus exists on how daily sedentary time (ST) and sedentary patterns (SP) affect health risks. Moreover, the relationship between SB and cardiovascular health (CVH), and the moderating role of physical fitness (PF), remains unclear—particularly when CVH is assessed through “Life’s Essential 8” (LE8). This study examines the associations between ST and SP on CVH and whether PF influences this relationship.

Methods: This is a population-based cross-sectional study with 394 apparently healthy adults (42,34±12,63years; 45,82% female; 25,21±3,93kg/m²) from Cadiz. ST and SP were measured with accelerometry, PF was assessed using a graded-exercise test for cardiorespiratory fitness (CRF) and a handgrip strength test for muscular strength. CVH was scored from 0 (poor) to 100 (high) using the LE8, which comprises diet, physical activity, smoking, sleep, body mass index, blood pressure, blood lipids and fasting blood glucose. Multiple linear regression models, adjusted for PF age, sex, and education level, were conducted, as well as separately by sex and age-groups (18–34years; 35–49years; 50–64years). The statistical significance was set at $p < 0,05$.

Results: The average ST was 10,30h±1,49/day, 30.74% in prolonged SP and 17,06% in very prolonged SP (>30 min

K. PARTICIPATORY RESEARCH IN HEALTH PROMOTION

and >60 min bouts, respectively). The mean LE8 score was $76,09 \pm 10,96$, indicating moderate CVH. There were no significant association between the ST ($\beta = -0,49; t = -1,34; p = 0,18$), nor the prolonged SP ($\beta = -0,05; t = -1,48; p = 0,14$), with LE8. However, very prolonged SP showed a positive tendency with the LE8 ($\beta = -0,12; t = -1,89; p = 0,06$); although this tendency disappears when adjusting for PF. In contrast, the PF were positively associated with the LE8 ($p < 0,001$ and $p < 0,01$, respectively). Separated by sex, all models were non-significant ($p > 0,05$). However, ST was negatively associated with LE8 ($\beta = -1,53; t = -2,46; p = 0,02$), only in the 50-64years group, but this association disappeared only after adjusting for CRF.

Conclusion: In apparently healthy adults, ST and prolonged SP were not significantly related to CVH, though very prolonged SP tend to harm CVH. Among middle-aged adults, ST was negatively associated with CVH, but CRF mediated this outcome. Overall, higher PF was positively related to CVH. Therefore, while sitting less might help, being fitter seems more crucial for CVH.

I-P-K.09

Exploring the Social, Cultural, and Environmental Barriers to Physical Activity among African Immigrant Women in the United States

G.O. Otchere¹

¹Arizona State University, College of Health Solutions, Phoenix, United States

Purpose: Despite the well-documented benefits of physical activity (PA), African immigrant women in the United States are less likely to meet PA guidelines than other population groups. Their participation in PA is influenced by the interaction of social expectations, cultural norms, and environmental factors that are not well understood. This study examines how cultural modesty norms, gendered expectations, and neighborhood environments affect PA participation. It also aims to identify culturally appropriate, community-based strategies to boost participation. The study is innovative in its focus on an understudied immigrant population and in integrating socio-ecological and cultural frameworks to understand multilevel influences on women's PA engagement.

Methods: A qualitative, exploratory approach was used, involving semi-structured interviews with African immigrant women living in urban and suburban areas across the United States. Participants were purposively selected to ensure diversity in country of origin, length of stay in the U.S., cultural background, and religious background. Thematic analysis, guided by the socio-ecological model, was employed to identify influences on physical activity across multiple levels, including individual, interpersonal, and environmental factors. This approach offers a comprehensive understanding of how cultural and environmental contexts shape women's physical activity behaviors.

Results: Preliminary analyses indicate that norms of modesty and cultural expectations related to gender and family roles often limit participation in public or mixed-gender exercise settings. Environmental barriers, such as limited sidewalks, poor lighting, and safety concerns, also lead to decreased activity levels. Nonetheless, peer networks, faith-based walking groups, women-only programs, and support from trusted community or faith leaders act as important facilitators. Variations in barriers and motivators are evident across different religious affiliations and lengths of residence in the U.S., emphasizing the need for comprehensive intervention strategies.

Conclusion: This study advances understanding of how culture, gender, and place intersect to influence health behaviors among African immigrant women, an underrepresented group in PA research. Findings highlight the importance of culturally tailored community-driven interventions that incorporate environmental support and social trust mechanisms. The study supports global efforts to promote equitable PA, providing recommendations for both high-income and low- and middle-income settings facing similar cultural integration challenges.

I-P-K.10

Cultural Food Mirages: Threats to Latine Food Access in a Southern California City

T.R. Pulido¹, J. Douglas¹, D.D. Payán¹

¹University of California, Irvine, Health, Society, and Behavior, Irvine, United States

Purpose: In the United States, standard food environment assessments often overlook how food access varies across income and culture characteristics. Such nuances may fail to capture nuances of Latino (Latine) food insecurity. This study examined the food environment of Latine residents in Costa Mesa, California, to test for „food mirages“—areas

K. PARTICIPATORY RESEARCH IN HEALTH PROMOTION

where nutritious food is available but unaffordable. Uniquely, we extended this framework to assess *cultural food mirages*, analyzing the availability and affordability of culturally acceptable foods. We asked: What are the barriers and facilitators to food access for Latine residents in Costa Mesa?

Methods: Adopting a Community-Based Participatory Research approach with *Resilience Orange County*, we recruited $n=37$ Latine residents. We utilized participatory mapping, a visual method where participants pinned locations on a digital interface to identify specific community assets and stressors. This generated spatial data points representing food access points and accompanying narratives. We analyzed the spatial distribution of food access points and paired them with recorded narratives explaining the „why“ behind the locations. Thematic coding followed a deductive approach, from food access and food mirage frameworks.

Results: Participants collectively mapped $n=217$ data points. Food access predominantly remained within Costa Mesa but spanned across Orange and Los Angeles counties. Qualitative analysis revealed high costs and transportation deficits as major hurdles, while resource-sharing networks and non-brick-and-mortar retail outlets (e.g., street vendors) were key facilitators. Analysis revealed evidence of a food mirage, because nutritious food was geographically available but economically inaccessible. We found evidence of a cultural food mirage, where cultural foods were available but priced higher than comparable options in neighboring cities and had limited selection ranges.

Conclusion: Cultural food mirages may place residents at greater risk of food and cultural insecurity with downstream implications for diet quality and food-related wellbeing. Participatory mapping illuminated spatial and economic nuances often missed by traditional audits, highlighting how residents navigate inequitable environments. Results suggest forces like gentrification may develop and sustain these mirages, threatening resident food insecurity and neighborhood stability. Policymakers must prioritize cultural acceptability in food policy development, and future research should examine the longitudinal impacts of cultural food mirages on diet quality.

Active Lives, Agile Mind: Coproduction and Pilot Evaluation of a Mixed Martialarts Programme for Older Adults

Z. Szekeres¹, G. Jennings¹

¹Cardiff Metropolitan University, Centre for Health, Activity and Wellbeing Research, Cardiff, United Kingdom

Purpose: The *Active Lives, Agile Mind* project aims to promote healthenhancing physical activity and improve cognitive function in older adults from diverse communities. The objective of the first coproduction phase was to develop a multicomponent exercise programme incorporating exercises and movements drawn from a range of martial arts. The objective of the second phase was to evaluate the pilot programme among women from ethnically diverse communities to assess its acceptability and its impact on emotional wellbeing, physical and cognitive function.

Methods: In phase one, the multicomponent *Movement Inspired by Martial Arts* (MIMA) programme was developed in Cardiff through an iterative coproduction process involving older adults, healthcare professionals, and thirdsector organisations. Workshops were used to identify key factors influencing physical activity and to design a hybrid martial arts programme with instructors and researchers, focusing on coordination, learning, and social interaction. In phase two, the MIMA pilot was delivered in collaboration with thirdsector organisations, with participants joining on a rolling basis. Data were collected over three months using qualitative methods and fieldbased physical and cognitive measures.

Results: The final programme includes noncontact martial arts movements designed to improve coordination and strength, alongside educational materials, group sessions, and structured social interaction to support adherence. Participants valued the coproduction process, and showcase events demonstrated strong engagement and enjoyment across diverse groups. Preliminary findings from phase two indicate high adherence, positive participant experiences, and improvements in physical function. Participants also reported benefits related to social interaction, flexibility, and balance. Currently, 22 participants are taking part, and data collection will continue until April 2026. Volunteer MIMA ambassadors are now being trained to help sustain and expand the programme.

Conclusion: Integrating coproduction with stakeholder engagement enhanced recruitment, acceptability, and perceived feasibility among older adults. Future work will focus on scaling the programme and adapting it for carers, people living with dementia, and volunteers, ensuring accessibility in both home and care settings. Building trust through compassionate public engagement and collaborative partnerships proved essential for promoting healthenhancing physical activity in underrepresented groups.

Protocol of PLANT-Z: How to Shift Generation-Z Towards More Plant-based Dietary Patterns?

V. Versele^{1,2}, M. Vanhove^{1,2}, E. Mertens³, P. Clarys³, W. Van Lippevelde^{2,4}, T. Deliens³

¹Vrije Universiteit Brussel, Department of Movement and Sport Sciences, Brussels, Belgium, ²Ghent University, Department of Marketing, Innovation and Organization, Ghent, Belgium, ³Vrije Universiteit Brussels, Department of Movement and Sport Sciences, Brussels, Belgium, ⁴Ghent University, Department of Public Health and Primary Care, Ghent, Belgium

Purpose: Although significant health and planetary benefits are associated with plant-based dietary choices, the intake of healthy and sustainable plant-based protein sources remains low in Belgium. Food choices of adolescents are shaped by complex individual and environmental factors whilst adolescents' behaviors may substantially influence future generations. Consequently, adolescents represent a crucial target group. However, evidence on adolescents' motivations and barriers regarding plant-based diets is limited, and effective intervention strategies to promote healthier and more sustainable diets are lacking. Therefore, the PLANT-Z project aims to collect pioneering data on sustainable plant-based dietary patterns in adolescents (14-18 years old), including those with a lower socio-economic status, and on how adolescents can be motivated to shift towards more healthy and sustainable plant-based dietary patterns.

Methods: A mixed-method and co-creation approach will be used. First, a cross-sectional study will be used to conduct needs assessment on adolescents' (determinants of) dietary behavior and acceptability for the transition towards more healthy and sustainable plant-based diets. These findings will be complemented by secondary analyses of national dietary intake data from the Belgian Food Consumption Survey. Second, intervention settings for the promotion of healthy plant-based diets will be determined through a literature search, after which their feasibility will be examined with school boards and parents through in-depth interviews. Based on the findings of the first and second step, an intervention strategy will be developed in a third step, making use of co-creation with adolescents from different education types in Belgium. Finally, the potential (short-term) effectiveness and feasibility of the co-developed intervention will be evaluated through pilot testing.

Results: Through this multifactorial approach we aim to develop an effective intervention through comprehensive insight into adolescents' capabilities, opportunities, knowledge, perceptions, facilitators, and barriers related to healthy and sustainable plant-based eating, as well as contextual and policy factors within school and home environments.

Conclusion: In conclusion, this research will generate foundational knowledge for shaping future co-created public health initiatives and supports more effective promotion of healthy and sustainable plant-based dietary patterns in adolescents.

I-P-K.13

Participatory Action Research to Promote Physical Activity System Change in Low Socio-economic Position (SEP) Neighbourhoods

B. van Aken¹, F. Popken², L. ter Harmsel-Nieuwenhuis³, K. Verkooijen¹

¹Wageningen University and Research, Health and Society, Wageningen, Netherlands, ²Hogeschool Inholland, Amsterdam, Netherlands, ³Hogeschool Windesheim, Zwolle, Netherlands

Purpose: Reducing socioeconomic health inequalities requires approaches that move beyond individual behaviour change and address structural barriers across multiple system levels. As part of a broader neighbourhood-based project, this study aims to improve access to physical activity among people in a low socio-economic position (SEP), by identifying systemic barriers and contributing to system-level change.

Methods: This study is embedded in the three-year participatory action research (PAR) project 'Wij(k) in Beweging' ('Neighbourhood on the Move'), conducted in three Dutch neighbourhoods. A participatory, multi-phase design was applied. Phase one has been completed and involved a local problem analysis, consisting of document analysis, stakeholder analysis, and semi-structured (group) interviews with people in a low SEP to identify systemic barriers and potential solutions to improve access to physical activity. Phases two and three are ongoing and involve the co-creation of a theory of change and its iterative implementation. Locally tailored solutions are being developed collaboratively with relevant stakeholders, including people with a low SEP.

Results: Phase one identifies interconnected, multi-level systemic barriers across all levels of the Socio-Ecological

K. PARTICIPATORY RESEARCH IN HEALTH PROMOTION

Model (SEM), including intrapersonal, interpersonal, organizational, environmental, and policy levels. Barriers among people in a low SEP are mental, physical, social, cultural, financial, and environmental. Furthermore, physical activity provision is perceived as inaccessible when insufficiently tailored or poorly visible. While overarching barriers are similar across neighbourhoods, their specific manifestations vary contextually. Professionals additionally highlight fragmented cross-sector collaboration as a constraint to accessible support structures. Examples of proposed solutions include strengthening cross-sector collaboration, simplifying financial support mechanisms, enhancing visibility of local opportunities, and tailoring provision to residents' lived realities. The co-created action plans are currently being finalised and will be presented at the conference.

Conclusion: This study provides insights into systemic barriers and solutions regarding physical activity among people in a low SEP. Our findings indicate that barriers described by people in a low SEP are rooted in deeper systemic determinants. Addressing these requires participative, system-level innovation that targets structural determinants of access.

I-P-K.15

Simultaneous Language Validation of the Physical Activity Domain of a Visually Enhanced Behavior Checklist.

L.K. Diaz Rios¹, M.K. Shilts², J. Joseph³, J. Aulakh⁴, C.M. Drake⁴, C. Davidson⁵, D. Beltran⁶, D. Perales⁷

¹University of California, Merced, Agriculture and Natural Resources, Merced, CA, United States, ²California State University, Sacramento, Sacramento, CA, United States, ³Rutgers University, Sacramento, CA, United States, ⁴University of California, Davis, Davis, CA, United States, ⁵University of California Agriculture and Natural Resources, Davis, CA, United States, ⁶University of California Agriculture and Natural Resources, Anaheim, CA, United States, ⁷Catholic Charities of California, Sacramento, CA, United States

Purpose: Accurate and consistent educational program evaluation requires linguistically appropriate, contextually relevant, and parsimonious measurement tools. The purpose was to test the validity and reliability of three items in the physical activity domain of a visually enhanced behavior checklist. The checklist is used to evaluate behavioral changes among English- and Spanish-speaking adults who participate in government-funded nutrition education programs in the United States.

Methods: Ten content experts reviewed existing items from validated tools that measured adherence to physical activity guidelines. A convenience sample of English- and Spanish-speaking adults with low incomes was recruited from community-based organizations and simultaneously engaged in subsequent tool testing. Face validation involved iterative cognitive interviews to improve clarity, semantic equivalence, and contextual relevance of text and accompanying photos. Test-retest (Kendall's tau-b) and internal consistency (Cronbach's coefficient alpha) reliability were examined by completion of the face-validated items at two time points (T1 & T2), four weeks apart.

Results: Three items were identified and adapted through expert appraisal. Adaptations included adding photographic representations of evaluated behaviors. Three rounds of in-person (n=32) or virtual (n=18) cognitive interviews with 24 English and 26 Spanish speakers yielded improvements in clarity and suitability, most involving photos. Face-validated items were completed by 209 respondents at T1 (English n=108, Spanish n=101) and 185 at T2 (English n=94, Spanish n=91). Temporal stability was stronger for the item of strength exercise (tau=0.63; English tau=0.63, Spanish tau=0.54), followed by the items of aerobic exercise (tau=0.53, English tau=0.51; Spanish tau=0.58) and physical activity (tau=0.52; English tau=0.45, Spanish tau=0.34). Internal consistency was acceptable for the three-item domain (alpha=0.76; English alpha=0.71, Spanish alpha=0.80).

Conclusion: Face validity of items that measure adherence to physical activity guidelines was established. Items in English showed better temporal stability, whereas internal consistency reliability was stronger for the three-item scale in Spanish. Although simultaneous language testing is resource-intensive, it enables equivalent accuracy and consistency in data collected in both languages. A tool administration guide is available to facilitate data collection.

K. PARTICIPATORY RESEARCH IN HEALTH PROMOTION

I-P-K.16

Co-designing an mHealth Intervention to Improve Health and Well-being in Individuals with Obesity: Stakeholder Perspectives on Eating-related Components

M. Ely¹, V. Horka¹, B. Kastovska¹, M. Volarikova Pindakova², O. Perski³, T. Vetrovsky⁴, S. Elavsky¹

¹Ostrava University, Department of Human Movement Studies, Ostrava, Czech Republic, ²Ostrava University, Department of Health and Social Studies, Ostrava, Czech Republic, ³Stockholm University, Department of Psychology, Stockholm, Sweden, ⁴Charles University, Department of Biomedical Sciences in Kinanthropology, Prague, Czech Republic

Purpose: Obesity is a significant public health concern, and digital technologies offer new opportunities for enhancing health and wellbeing among individuals with obesity. Co-design addresses challenges in developing effective, engaging and sustainable mHealth interventions. This study aimed to gain stakeholder insights to inform eating-related mHealth intervention components by assessing their feasibility, acceptability, and implementation potential, in addition to identifying barriers and facilitators for successful integration into everyday life.

Methods: The co-design activities were informed by the Double Diamond framework. This analysis reports findings from the discovery phase. Twelve experts (medical doctors, nutritionists) were recruited through purposive and chain-referral sampling and divided into two workshops. The workshops utilized guided discussions and group dynamics to gather data. Discussions followed a structured funnel approach, were audio- and videorecorded and transcribed verbatim. Data were coded in MAXQDA and analyzed through Clarke's situational analysis. Cartographic techniques were employed in situational mapping to analyze elements of eating-related behavior.

Results: The analysis maps the situation through heterogeneous elements influencing an individual's motivation and capacity to adopt and adhere to dietary changes, shaping the process of change. Socio-economic and demographic factors shape the conditions, opportunities, and constraints of the intervention context. Older adults find it harder to initiate change but maintain habits once engaged. Younger adults start readily but struggle with adherence. Educational background influences how individuals negotiate eating-related recommendations. Those with lower education may follow instructions readily, while those with higher education may intellectualize non-compliance. Women adhere longer when motivated by appearance but struggle to prioritize self-care, while men seek help for health issues and may relapse more easily. Cultural norms, family traditions, and stigma shape everyday eating practices. Barriers and facilitators function as dynamic temporal elements evolving throughout an individual's change journey. Digital technologies act as non-human elements. Perceived authenticity, tone of communication, feedback mechanisms, and their usability influence trust, motivation, and engagement. The mHealth intervention should be personalised, socially embedded and responsive to individuals' everyday contexts.

Conclusion: The co-design approach yielded insights into situational complexity of individuals with obesity and informed mHealth strategies targeting motivation, social and environmental factors, self-efficacy, self-regulation, and digital-related engagement challenges.

II-P-K.02

Financial Strain, Depressive Symptomatology, and Health Behaviors among Rural Adults in the Southeastern United States

L. O'Neal¹, T. Nesbit¹, M. Jones¹

¹University of Florida, Family, Youth and Community Sciences, Gainesville, United States

Purpose: Rural communities experience a disproportionate burden of cardiometabolic risk factors, such as low levels of physical activity, poor dietary practices, and limited access to food, physical activity, and health care resources, that contribute to higher rates of morbidity and mortality among rural adults. While research has demonstrated how limited access to resources influence healthy lifestyle choices, much less is known about the relationship between individual level psychosocial factors like financial strain and depressive symptomatology and lifestyle behaviors among rural adults. Understanding the role of multilevel factors is important for designing interventions that address both structural barriers and individual level factors that may influence health behaviors and contribute to rural health disparities. The current study: 1) describes the health behaviors of rural adults and 2) examines associations between financial strain, depressive symptomatology, and health behaviors among rural adults.

Methods: The Rural HEALTH (Healthy Eating and Active Lifestyle Tools for Health) Program seeks to understand and address multi-level factors, including individual, social, community, and environmental, that influence the eating

K. PARTICIPATORY RESEARCH IN HEALTH PROMOTION

and physical activity behaviors of rural adults. Program participants were recruited from four rural counties in the southeastern United States. Baseline data were collected from 210 participants enrolled in the Rural HEALTH program between 2018-2020. We conduct a cross-sectional analysis, utilizing descriptive statistics, bivariate, and multivariate analyses to examine relationships between financial strain, depressive symptomatology, fruit and vegetable consumption, sugar-sweetened beverage consumption, and physical activity patterns.

Results: The mean age of the sample is 56 years. Most participants were female (79%) and Black American (90%). Descriptive statistics of fruit and vegetable consumption, water and sugar-sweetened beverage consumption, and physical activity behaviors of rural adults are provided. Preliminary bivariate and multivariate analysis reveal associations between financial strain, depressive symptomatology, water, and sugar-sweetened beverage consumption.

Conclusion: Financial strain and mental well-being are associated with lifestyle behaviors among rural adults. Despite study limitations, findings suggest that additional research is needed to examine how psychosocial risk factors contribute to unhealthy lifestyle behaviors among rural adults. Understanding the complete range of factors associated with lifestyle behaviors is critical for developing multilevel interventions to reduce rural health disparities.

II-P-K.03

Managing Cardiometabolic Diseases through Culturally Tailored Nutrition Education and Medically-tailored Groceries for Hispanic/Latine Communities

A. Evans¹, E. Olson¹, I. Martinez-Boelk², A. Wasielewski², A. Crusan¹

¹St. Catherine University, Nutrition and Dietetics, St. Paul, United States, ²St. Catherine University, Public Health, St. Paul, United States

Purpose: Classes providing culinary instruction including nutrition education tailored to specific ethnic groups are an effective way to support individuals managing chronic diseases. Additionally, supporting adherence to educational concepts may be reinforced at home with improved food access via medically-tailored groceries (MTG). This project aims to evaluate the impact of culinary nutrition education classes supported by MTG for Hispanic/Latine individuals with cardiometabolic diseases.

Methods: Participants with Type 2 Diabetes (DM2) and/or cardiovascular diseases (CVD) were recruited from a community health clinic and enrolled in at least one culinary nutrition education class taught by Nutrition/Dietetics and Public Health students. Participants completed pre-post evaluations with likert scales measuring their understanding of managing a chronic disease diagnosis with food choices and open ended questions to evaluate the impact of the class on disease-specific knowledge and class satisfaction. Participants received MTG to support nutritionally-dense meals at home and to incorporate education from the class(es) into their daily lives.

Results: Preliminary results from 17 (3 males, 14 females) pre-post class surveys indicate increased understanding of the way DM2 or CVD affects their body, the way food affects their blood glucose and/or blood pressure and blood lipids, and what blood glucose, blood pressure, and/or blood lipid readings show good control of DM2 or CVD. Importantly, participant scores increased on average when asked to rate their confidence in managing DM2 or CVD with food. Participants participating in more than one course were more likely to rate their knowledge higher during the second pre-survey compared to the first time taking the course. Moreover, 100% of returning participants (n= 11) indicated the MTG supported at-home alignment with diet patterns to support their chronic disease. Overall, participants rated the course 4.87/5 for satisfaction and 100% of the participants indicated the material was culturally-appropriate. Participants expressed themes of empowerment to manage their chronic disease, share what they learned with family and friends, and prepare new recipes at home.

Conclusion: Attending at least one interprofessional culinary nutrition course with culturally-appropriate MTG may improve individuals' confidence in managing chronic diseases such as DM2 and CVD via food.

II-P-K.04

Predictors of Sleep Quality among Lower Secondary School Teachers in the Porto District

D. Barros¹, J. Martins¹, L. Bohn², L. Miranda¹

¹ESS IPP, Porto, Portugal, ²FADE UP, Porto, Portugal

K. PARTICIPATORY RESEARCH IN HEALTH PROMOTION

Purpose: Poor sleep quality is a growing occupational health concern among teachers, given its potential impact on physical and psychological well-being. This study aimed to identify predictors of sleep quality among lower secondary school teachers working in public schools in the Porto district, Portugal.

Methods: A cross-sectional, observational, and analytical study was conducted using an online questionnaire that included sociodemographic and lifestyle variables, the Pittsburgh Sleep Quality Index (PSQI), and the Perceived Stress Scale (PSS). Multiple linear regression analyses were performed using an adjusted model controlling for age, sex, body mass index (BMI), physical activity, and smoking habits, to identify factors associated with PSQI scores.

Results: The sample ($n = 43$) was predominantly female (55.8%) with a mean age of 44.2 ± 8.07 years. Most participants reported engaging in regular physical activity (86%), poor sleep quality (PSQI mean = 7.6 ± 3.12), and a moderate level of perceived stress (PSS mean = 24.3 ± 6.33). Regression analysis revealed that stress level ($B = 0.353$; $p < 0.001$), smoking habits ($B = -4.031$; $p = 0.007$), body mass index ($B = 0.023$; $p = 0.004$), time before bedtime without technology use ($B = -0.277$; $p = 0.018$), and maintaining a bedtime routine ($B = -1.282$; $p = 0.033$) were significant predictors of sleep quality (adjusted $R^2 = 0.688$).

Conclusion: The findings suggest that higher stress levels, smoking, and increased BMI are associated with poorer sleep quality, whereas a longer period of technology abstinence before bedtime and maintaining a consistent pre-sleep routine were linked to better sleep outcomes. Despite the study's limitations, these results highlight the importance of implementing workplace health promotion strategies targeting stress management, healthy lifestyle behaviors, and sleep hygiene education to support the well-being and occupational functioning of teachers.

II-P-K.05

Facilitators and Barriers to Migrational Transitions and Its Impact on Type 2 Diabetes in Somali Elders Living in Minnesota

M. Irobe¹, N. Abdi¹, A. Crusan¹

¹St. Catherine University, Nutrition and Dietetics, St. Paul, United States

Purpose: Somali elders experience significant transitions impacting their health when migrating to the United States (U.S.) including cultural shifts, changes in diet, and challenges understanding the complex healthcare system. More importantly, dietary changes are associated with increased prevalence of Type 2 Diabetes (DM2) among Somali immigrants; however, little is known regarding impacts of migration on older Somali adults managing chronic diseases. This study aims to understand the impact of migrational transitions among Somali elders related to risk for and management of DM2.

Methods: Somali participants with DM2 were recruited from community sites and participated in 30-minute ethnographic interviews to understand intersection of DM2 management and immigrant identity using community-engaged research approaches. Demographic surveys and diet quality questionnaires were administered and analyzed using REDcap and Excel. Interview themes and subthemes were determined by identifying saturation of topics via the Framework Method.

Results: Fourteen Somali participants (7 male, 7 female) with an average age of 64.5 ± 9.6 years completed the interviews. Three themes associated with migrational transitions and managing DM2 emerged: 1) cultural norms frame perceptions around health and DM2 diagnosis; 2) systemic impacts of stress and isolation post migration; 3) religion, cultural knowledge, and support from family/community were facilitators; and 4) lower socioeconomic status, low health literacy, food quality and quantity access, and occupational limits to movement, are barriers. In particular, participant 14 noted that familial pressures for women (and mothers) heightened barriers to self-care related to aging and managing DM2 stating, "We as a society have normalized putting your child's life over a mother's... Everything is for the kids. We forget ourselves. Even our food. That's where most of these illnesses come from."

Conclusion: Migration from Somalia to the U.S. in older adulthood can affect cultural norms, food access, quality & portions, physical activity, and healthcare delivery, all of which impact DM2 management. It is evident that impacts of stress from migration, resettlement, and gender norms place increased pressure on women, exacerbating poor health outcomes. Increased access is needed for transitional services for chronic disease management in older adults: from nutrition education to healthcare system support.

K. PARTICIPATORY RESEARCH IN HEALTH PROMOTION

II-P-K.07

Co-designing a System-based Intervention Approach to Stimulate Physical Activity and Motor Competence in 0-4-year-Old Children – The ASAS Project

F. Bartels¹, J. Gubbels¹, L. Kromkamp², D. Van Kann^{1,2}, V. Verbestel¹, S. Gerards¹

¹Maastricht University, Health Promotion - Research Institute for Nutrition and Translational Research in Metabolism (NUTRIM), Maastricht, Netherlands, ²Fontys University of Applied Sciences, School of Sport Studies, Eindhoven, Netherlands

Purpose: Early childhood (0-4 years) is a critical period for developing motor competence (MC) and physical activity (PA) habits. However, compliance with PA guidelines among young children remains low, and MC levels are declining. While early intervention is essential, most existing interventions focus on school-aged children, and the limited interventions for 0-4-year-olds rarely adopt a system-based, multi-component perspective. Furthermore, stakeholder engagement, such as collaborating with primary caregivers and professionals working with children or families, is recognised as crucial for designing feasible interventions that can be successfully implemented in practice. This study, therefore, aimed to co-design a system-based intervention approach with primary caregivers and professionals to stimulate PA and MC in Dutch children aged 0–4 years.

Methods: An iterative co-design methodology was applied, consisting of multiple participatory sessions with primary caregivers and professionals. System insights from a broader research consortium informed the development process, and active working forms (from the A-Z of Methods of Kerr et al., 2023), alongside theoretical frameworks for intervention development (e.g., Behaviour Change Wheel) and implementation science (e.g., Updated Consolidated Framework for Implementation Research) were used as guidance. Furthermore, qualitative and quantitative data were collected on participants' background characteristics (questionnaire), acceptability, appropriateness, and feasibility of the approach (observations and focus group discussions) and the group process (focus group discussions and evaluation form).

Results: System factors influencing young children's PA and MC were discussed, and screen use behaviours, physical environment, parental insecurity/doubts and the societal trend of individualism were identified as key factors. Subsequent sessions focused on generating ideas for intervention and implementation strategies, which the research team synthesised into intervention principles by combining participants' insights with the theoretical frameworks. Prototypes of these intervention principles will be developed and refined in future sessions to enhance fit with real-world contexts.

Conclusion: By actively involving primary caregivers and professionals, we work towards an innovative, system-based intervention approach that stimulates PA and MC in young children. The flexible methodology of an iterative co-design process allowed integration of emerging insights from the broader consortium, ensuring responsiveness to the dynamic, real-world context of intervention development for early childhood.

II-P-K.08

Beyond the Clinic: Medical Students' Perceptions of Behavioral Drivers of Nutrition and Physical Activity and Obesogenic Environments for Children in the Dominican Republic

K. Polanco¹, J. Yudkin²

¹Universidad Iberoamericana, Medicine, Santo Domingo, Dominican Republic, ²Texas A&M University, Health Behavior, College Station, United States

Purpose: In rapidly urbanizing middle-income countries like the Dominican Republic, childhood obesity is driven by complex socio-ecological factors. While medical training often emphasizes individual clinical outcomes, there is a need to understand how future physicians conceptualize the environmental determinants of nutrition and physical activity (PA). This study explored medical students' perceptions of the community-level barriers to healthy eating and active living in their local contexts.

Methods: Using a Photovoice-informed qualitative design, two audio-recorded focus groups were conducted with medical students (n=18) at a university in the Dominican Republic. Participants captured and presented visual prompts depicting local community factors. Guided discussions focused on the interplay between the built environment and pediatric health behaviors (dietary intake and sedentary patterns). Data were analyzed using thematic analysis to identify perceived determinants and proposed multi-level behavioral interventions.

K. PARTICIPATORY RESEARCH IN HEALTH PROMOTION

Results: Preliminary themes highlighted significant environmental constraints on energy balance behaviors. Regarding nutrition, medical students identified the pervasive marketing of ultra-processed foods, the reward culture of sweets in schools, and food deserts surrounding childcare centers. Regarding physical activity, participants emphasized the lack of safe public infrastructure, the normalization of sedentary behaviors with digital devices and the physical decay of playgrounds. Socioeconomic pressures were seen as a cross-cutting barrier, forcing a reliance on low-cost, nutrient-poor diets. Participants proposed shifting from individual-focused counseling in a clinical setting based off their experience in clinical rotations to multi-level strategies, including school-based nutritional policy reform and urban infrastructure maintenance to support sidewalks and play.

Conclusion: Medical students demonstrated a nuanced understanding of how obesogenic environments in Santo Domingo undermine healthy nutrition and PA. These findings suggest that medical education should move beyond clinical weight management to include systems-thinking and behavioral advocacy. Integrating these community-informed perspectives can better equip future physicians to address the structural drivers of childhood obesity through context-responsive interventions.

II-P-K.09

Assessing Physical Activity Barriers by Photovoice and Computer-assisted Neighborhood Visual Assessment System (CANVAS): A Qualitative Study

D. Sandler¹, S. Lopez De Leon¹, M. Andrews¹, E. Aquino Peterson¹, J. Ceasar¹, S. Claudel¹, K. Tamura², L. Ortiz-Whittingham¹, K. Thompson¹, S. Regan³, Y. Baumer¹, V. Mitchell¹, N. Farmer⁴, F. Osei Baah⁵, S. Mooney⁶, T. Powell-Wiley¹

¹National Institutes of Health, National Heart, Lung, and Blood Institute, Bethesda, United States, ²National Institutes of Health, National Institute on Minority Health and Health Disparities, Bethesda, United States, ³Columbia University, Mailman School of Public Health, New York, United States, ⁴National Institutes of Health, Translational Biobehavioral and Health Disparities Branch, Clinical Center, Bethesda, United States, ⁵Emory University, Nell Hodgson Woodruff School of Nursing, Atlanta, United States, ⁶University of Washington, Department of Epidemiology, School of Public Health, Seattle, United States

Purpose: Given the importance of neighborhood built environments in physical activity (PA) and related disparities in cardiovascular health, we assessed neighborhood disorder as a barrier to PA among African American (AA) women using the Computer-Assisted Neighborhood Visual Assessment System (CANVAS) and Photovoice. The purpose of this study was to compare the efficacy of these methodologies in evaluating neighborhood disorder in under-resourced Washington, D.C. wards and assess the impact of built environment on PA. We hypothesized that both Photovoice and CANVAS would capture important aspects of neighborhood disorder, but Photovoice would provide a community-centered perspective on how neighborhood factors detected via CANVAS influence PA. This study is the first to compare elements of the neighborhood environment captured by CANVAS and Photovoice to assess AA women's likelihood to engage in PA.

Methods: Participants were enrolled in the Washington, D.C., Cardiovascular Health and Needs Assessment. They participated in walking groups, and Photovoice was employed to identify environmental barriers to PA. CANVAS was then adapted to identify markers of neighborhood disorder in photographs taken by participants. This study employed a qualitative design using reflexive thematic analysis in which auditors utilized CANVAS and Photovoice to code themes represented by each image. Auditors initially identified 14 themes, which were then consolidated into five overarching themes.

Results: The study cohort consisted of 41 AA women (age = 61.9±10.2 years). Photovoice and CANVAS informed the creation of five themes highlighting barriers to PA: Physical Safety, Personal Safety, Availability of Resources, Inadequate Maintenance, and Urban Development. CANVAS was effective in assessing the fixed, physical aspects of the built environment that may impact PA. However, Photovoice provided more context to the participants' photographs as barriers to PA.

Conclusion: Our findings suggest that objective measures, such as CANVAS, are effective at capturing physical aspects of the environment that affect PA levels, but community-based participatory research methods, such as Photovoice, provide insight into CANVAS outcomes and reveal additional barriers to PA. This study provides key insights that can be used to develop pathways for the integration of community voices into local government policies and urban planning that reduce environmental barriers to PA.

K. PARTICIPATORY RESEARCH IN HEALTH PROMOTION

II-P-K.10

Empowering Truck Drivers to Enact Change in their Working Environments for Healthier Lifestyles – A Feasibility Study

L. Wang¹, J. King¹, E. Stamp¹, P. Lester¹, S. Portillo², A. King², S. Clemes¹

¹Loughborough University, School of Sport, Exercise and Health Sciences, Loughborough, United Kingdom, ²Stanford University, School of Medicine Department of Epidemiology and Population Health, Stanford, United States

Purpose: Truck drivers make an essential contribution to the UK economy, yet they are exposed to various health-related risk factors associated with their occupation, and experience substantial health inequalities. Improving drivers' working environments, to support driver health and wellbeing is a government priority, however driver engagement in identifying priority areas and needs has been sparse. This study aims to assess the feasibility of adopting a mixed-methods citizen science approach, using the *Our Voice* "Discovery Tool" app, with truck drivers to empower drivers to positively impact their working environments.

Methods: This ongoing study will assess the feasibility of involving truck drivers in the four-step *Our Voice* process of 'Discover, Discussion, Activate and Change'. A target sample of 10 citizen scientists (truck drivers) will be recruited. Drivers will be requested to collect data using their smartphone via the Discovery Tool app, guided by the question "what supports your good health, and what negatively impacts your health within your working environment?" Collected data will include geotagged photographs with drivers' voice or text comments and good/bad ratings. Following data collection, drivers will be invited to a meeting to discuss data collected and identify priority areas and key stakeholders to invite to a further meeting to discuss actionable changes.

Results: To date, 4 male truck drivers (aged 40-64 years) have completed data collection for the 'Discover' step. Data have been collected across 16 locations at diverse times. 45 photographs have been taken, accompanied by 5 audio recordings and 32 text comments. Aspects of drivers' working environments captured thus far include toilets, showers, food options, rest areas, lighting, and road surface conditions. Full results of the project 'Discover' and 'Discuss' steps will be presented at the conference.

Conclusion: Findings to date demonstrate the feasibility of using the Discovery Tool with a sample of truck drivers. This approach offers potential to provide valuable insights into drivers lived experiences and their perceived barriers to adopting healthy lifestyle behaviours within the confines of their working environments. The *Our Voice* citizen science method holds potential to positively impact policy and environmental changes for this unique and understudied population.

II-P-K.11

Building a Rapid-response Cohort to Capture Emerging Trends in Adolescent Health

K. Loth¹, K. Johnson², N. Larson³, D. Neumark-Sztainer²

¹University of Minnesota, Department of Family Medicine and Community Health, Minneapolis, Minnesota, United States,

²University of Minnesota, Division of Epidemiology and Community Health, Minneapolis, Minnesota, United States, ³Texas Tech University, Nutritional Sciences, Lubbock, Texas, United States

Purpose: While traditional surveys provide valuable insights into adolescent health, they are less well-suited for capturing immediate impacts of current events, policy changes or social trends affecting youth and families. To address this, we are piloting a rapid-response survey infrastructure that complements traditional approaches by generating timely, community-informed data on emerging issues. Combining traditional and rapid-response methods has the potential to produce more responsive, actionable insights, enabling public health efforts to align closely with the lived experiences of youth.

Methods: The rapid-response cohort is embedded within the longitudinal Project EAT (Eating and Activity over Time) study. Participants are recruited from existing, well-characterized cohorts, including EAT IV (n=1,696), EAT 2010 (n=1,017), and their adolescent children (n=906), enabling an intergenerational design that includes parent-adolescent dyads alongside non-parent adults. Eligible participants include adolescents (ages 13-18), parents, and non-parent adults.

Participants provide consent (or assent, with parental consent for adolescents) to receive up to five brief (3-5 minute), SMS-delivered surveys annually. Surveys may be sent to the full cohort or targeted to subgroups based on characteristics of interest, enabling efficient, tailored data collection on emerging topics. Content is continuously

K. PARTICIPATORY RESEARCH IN HEALTH PROMOTION

informed by youth and professional community advisory boards to ensure relevance and inclusivity.

Results: We established a scalable infrastructure to support ongoing, low-burden, rapid-response data collection, including procedures for cohort recruitment and consent for ongoing contact, SMS-based survey delivery, and governance processes to prioritize emerging topics. Standardized workflows for rapid question development and vetting, brief survey design templates, and an IRB strategy enabling expedited review have been implemented to support timely deployment.

This system allows the team to develop and deploy brief surveys in near real time in response to current events and evolving public health concerns while maintaining methodological rigor and community engagement. Initial pilot implementation is ongoing and is assessing feasibility (e.g., response rates, completion time) and acceptability (e.g., perceived burden, satisfaction with survey format).

Conclusion: A rapid-response cohort model offers a promising approach for time-sensitive adolescent health research. By addressing limitations of traditional surveys, this infrastructure can generate actionable, context-sensitive data to complement existing surveillance tools.

II-P-K.12

A Co-design Study to Tailor a Theoretically-informed, Evidence-based Physical Activity Behaviour Change Intervention to Postpartum Individuals with Lumbopelvic Pain

H. Hollman¹, J. Pulsifer^{2,3}, P. Sun⁴, K. Parise^{5,6}, S. Douglas⁷, J. Williams⁸, N. Kaur⁹, M. Pineau¹⁰, S. Liu¹, M.H. Davenport¹¹, R.E. Rhodes¹

¹University of Victoria, School of Exercise Science, Physical & Health Education, Victoria, Canada, ²University of British Columbia, Vancouver, Canada, ³Full Circle Physiotherapy, Vancouver, Canada, ⁴Independent, Ottawa, Canada, ⁵McMaster University, Hamilton, Canada, ⁶Blueberry Therapy, Dundas, Canada, ⁷Independent Practitioner, St. Thomas, Canada, ⁸The Chiropractic Wellness Studio, Edmonton, Canada, ⁹Synergy Rehab, Surrey, Canada, ¹⁰Independent, Kelowna, Canada, ¹¹University of Alberta, Faculty of Kinesiology, Sport, and Recreation, Edmonton, Canada

Purpose: Postpartum physical activity (PA) is associated with improved physical and mental health, yet 55% of postpartum individuals do not meet PA recommendations. Concurrently, one quarter of postpartum individuals experience lumbopelvic pain (LPP), and available PA behaviour change interventions are not tailored to postpartum LPP. In addition, most postpartum PA interventions are informed by social cognitive frameworks which do not account for the commonly observed PA intention-behaviour gap. The multi-process action control (M-PAC) framework includes post-intentional constructs, such as emotion regulation, habit, and identity, that facilitate intention-behaviour translation. The purpose of this study was to co-design an evidence-based, theory-informed mobile application (app) PA intervention tailored to postpartum individuals with LPP.

Methods: Ten community partners (n = 5 individuals with postpartum LPP and n = 5 healthcare providers) partook in a three-phase iterative co-design study to tailor a pre-existing PA app prototype (that currently targets adults 18+ years) to postpartum individuals with LPP. This involved 1) interviews to determine high-level modifications, 2) an online survey (4-months after the interviews) to determine satisfaction with and feedback of the updated app, and 3) think-aloud interviews (2-months after the surveys) to assess usability, receive final feedback about the app and complete a second online survey to determine the level of meaningful project engagement. App modifications were completed following each round of feedback.

Results: The first interview highlighted the need for additional content that captures the complexity of the postpartum LPP experience. Additionally, partners recommended a focus on habit development by incorporating PA into the pre-existing postpartum and infant schedule. The first online survey demonstrated overall satisfaction with the app (M = 3.78±.67 out of 5) and suggestions including reduced text, improved visual display, and increased interactivity. Think-aloud interviews confirmed that the app was user-friendly and ready for pilot testing. The second online survey portrayed extremely meaningful project engagement by partners (M = 93.69±9.02 out of 100).

Conclusion: This study served as an example of co-design methodology that can meaningfully engage knowledge users in the development of a theory-driven evidence-informed PA intervention. The next phase of app development will involve a pilot test among postpartum individuals with LPP.

II-P-K.13

Participatory Co-creation to Promote Active Outdoor Play and Healthy Dietary Behaviours in Children: The B-Challenged Project in Spain

P. De Miguel-Etayo^{1,2}, I. Rueda-De Torre^{1,2}, M. Domínguez-García³, L. Arango-Schmitt⁴, R. Wink⁵, T. Altenburg⁵, L. Moreno Aznar^{1,2}, C. Bartolomé³, on behalf of the B-Challenged Consortium

¹Growth, Exercise, Nutrition and Development (GENUD) Research Group, Instituto Agroalimentario de Aragón (IA2), Institute for Health Research Aragón (IIS Aragón), University of Zaragoza, Zaragoza, Spain, ²CIBEROBN, (Physiopathology of Obesity and Nutrition CB15/00043), Institute of Health Carlos III (ISCIII), Madrid, Spain, ³Primary Health Care Research Group of Aragón (GAIAP), Institute for Health Research Aragón (IIS Aragón), Aragonese Health Service, Zaragoza, Spain, ⁴University of Zaragoza, Department of Psychology and Sociology, Zaragoza, Spain, ⁵Amsterdam UMC, Vrije Universiteit Amsterdam, Department of Public and Occupational Health, Amsterdam Public Health Research Institute, Amsterdam, Netherlands

Purpose: The European B-Challenged project aims to reduce inequalities in access to active outdoor play and healthy dietary behaviours among children from socioeconomically disadvantaged backgrounds through co-created interventions targeting physical and social environments. This study presents the initial phase of the project in Zaragoza (Spain), which aimed to identify needs, barriers, and opportunities to promote healthy behaviours from the perspective of children and key stakeholders using a participatory and intersectoral approach. The study's innovation lies in the systematic application of participatory methodologies adapted for children to inform the design of contextually relevant and sustainable interventions.

Methods: A participatory evaluation is being conducted in the Arrabal neighbourhood (Zaragoza). Participants include 25 children aged 10–12 years from Tío Jorge Primary School. Adapted participatory methods, including timelines, collective mapping, and causal loop diagrams, are used to identify barriers and facilitators related to active outdoor play and healthy dietary behaviours. In parallel, participatory sessions were conducted with key adult stakeholders from the school and community environment. Process evaluation includes direct observation, structured reflections by the facilitation team, and continuous participant feedback. Weekly co-creation sessions with 6th-grade students are currently ongoing to design and implement actions targeting the physical and social environment.

Results: Preliminary findings identify multiple barriers within the physical and social environment, including limited access to safe play spaces, high availability of unhealthy food options, and a predominance of sedentary activities. Potential facilitators were also identified, particularly related to the school environment, community engagement, and children's motivation to improve their neighbourhood. The participatory process showed high levels of engagement and ownership among participants and is generating context-specific action proposals currently under implementation.

Conclusion: Findings suggest that participatory approaches involving children are feasible and valuable for identifying contextual determinants of physical activity and dietary behaviours in disadvantaged settings. This study contributes to the development of context-based interventions to reduce childhood health inequalities and provides evidence on co-creation strategies in behavioral nutrition and physical activity promotion.

II-P-K.14

BODY IMAGE AND LIFESTYLE OUTCOMES FOLLOWING PARTICIPATION IN FITSPIRIT: THE ROLE OF ADHERENCE AND BASELINE INTENTIONS

M. Bordeleau¹, R. de Fátima Guimarães², M.-È. Mathieu^{3,4}, S. Panahi^{1,5}, N. Alméras^{1,6}, S. Bucher Della Torre⁷, D. Larose^{1,6,8}, V. Drapeau^{1,6,8}

¹Université Laval, Département de Kinésiologie, Québec, Canada, ²Université du Québec à Trois-Rivières, Département des Sciences de l'Activité Physique, Trois-Rivières, Canada, ³Université de Montréal, École de Kinésiologie et des Sciences de l'Activité Physique, Montréal, Canada, ⁴Centre de Recherche Azrieli du CHU Sainte-Justine, Montréal, Canada, ⁵Canadian Nutrition Society, Ottawa, Canada, ⁶Centre de Recherche de l'Institut Universitaire de Cardiologie et de Pneumologie de Québec - Université Laval (IUCPQ-UL), Québec, Canada, ⁷HES-SO University of Applied Sciences and Arts Western Switzerland, Department of Nutrition and Dietetics, Geneva, Switzerland, ⁸Centre Nutrition, Santé et Société (NUTRISS), Institut sur la Nutrition et les Aliments Fonctionnels (INAF) - Université Laval, Québec, Canada

Purpose: Physical activity (PA) declines in adolescence, especially among girls. *FitSpirit* is a girls-only extracurricular PA program designed to promote PA. This study examined whether participation in *FitSpirit* was associated with

K. PARTICIPATORY RESEARCH IN HEALTH PROMOTION

changes in body size perception (BSP), body size dissatisfaction (BSD), and lifestyle habits; and whether these associations were influenced by weight intentions, weight status, and BSP-BSD profiles.

Methods: Participants ($n=293$, $14.5\pm1.5y$) enrolled in *FitSpirit* with data collected PRE-POST program. Self-reported measures included height and weight (zBMI), *FitSpirit* participation (total sessions), lifestyle habits (PA, screen-time, sleep, fruit and vegetable intakes), and BSP-BSD (Collins scale). Subgroup analyses were conducted according to baseline weight-action intentions (lose weight; control-maintain weight; gain weight; trying nothing), body weight status (underweight; normal weight; overweight; obesity), and BSP (underestimate; accurate; overestimate) and BSD (desire to be thinner; satisfied; desire to be bigger). Pre-post changes were tested with paired t-tests. Participation effects were examined using Pearson correlations and adjusted models (baseline, zBMI), and stratified analyses were conducted to explore effect modification.

Results: Overall, BSP decreased from PRE to POST ($\Delta=-0.21$; $p<0.01$), indicating a shift toward more accurate perceived body size, whereas BSD and lifestyle habits remained stable. *FitSpirit* participation was not associated with changes in BSP-BSD and lifestyle habits and subgroup analyses did not reveal any interactions for subgroup analyses. Stratified analyses showed that, based on baseline BSP profile, girls who initially “underestimated” or “overestimated” their body size shifted toward a more accurate perception over time ($\Delta=+0.53$; $p<0.05$ and $\Delta=-0.66$; $p<0.05$, respectively). Similarly, when stratified by baseline BSD profile, girls who “desired to be thinner” and those who “desired to be bigger” showed a shift toward a more accurate BSP ($\Delta=+0.18$; $p<0.05$ and $\Delta=+0.37$; $p<0.05$, respectively). Girls living with obesity presented a more accurate BSP ($\Delta=+1.26$; $p<0.05$) and a significant increase in PA ($\Delta=+17.7$ min/day; $p<0.05$).

Conclusion: Following *FitSpirit* participation, BSP trended toward greater accuracy, particularly among girls with baseline misperception or dissatisfaction. PA increased among girls living with obesity, suggesting potential benefits for higher-risk participants.

II-P-K.15

Centering Community Voices to Promote Weight-related Health in the Next Generation: A Multi-community Advisory Board (CAB) Approach

V. Piram¹, K. Johnson¹, M. Eisenberg², D. Neumark-Sztainer¹

¹University of Minnesota, Division of Epidemiology and Community Health, Minneapolis, United States, ²University of Minnesota, Department of General Pediatrics and Adolescent Health, Minneapolis, United States

Purpose: It is important to ensure that health research is relevant to the communities being studied. This work outlines the integration of adolescent, young adult, and professional community advisory boards (CABs) into Project EAT (Eating and Activity over Time), a longstanding, large cohort study examining the broad spectrum of eating, activity, and weight-related health in young people.

Methods: Over the last three decades, Project EAT has continuously sought input from young people. Our current research is focused on the next generation (Gen Z). We will conduct a survey with a sample of adolescents and young adults from across the United States. In addition, we will survey the original Project EAT cohorts who are now adults, as well as their adolescent children, to learn more about intergenerational trajectories. The *EAT Next Generation* study established a formal and robust process for partnering with three CABs to enrich all aspects of our study: an adolescent CAB (ages 13-17y), a young adult CAB (ages 18-25y), and a professional CAB made up of multi-disciplinary health experts. Over the course of the next six years, we plan to meet with each CAB 2-4 times per year and encourage bi-directional communication to keep an open line of idea-sharing and build genuine connection with our research partners.

Results: In the first year of our study, we have developed and introduced the CABs into our program of research and have already received useful information to guide our study. Through this collaborative process, we sought input from our CABs when identifying and refining key health priorities, such as the rising influence of weight-loss medications on social media and peer environments and current stressors facing Gen Z. The young adult group guided the refinement of our focus group questions, and our adolescent CAB provided feedback to improve the language of our national survey to ensure comprehension and relevance.

Conclusion: Working with CABs allows us to center our focus on concerns of greatest value to stakeholders but does not come without challenges. Insights into the advantages and challenges of incorporating CABs into a large research study will be shared at the conference.

I-P-L.02

Development and Implementation of a Diabetes Nutrition Education Curriculum “Train the Trainer” Opportunity to Build Capacity for Nutrition Educators who Serve Indigenous Adults with Diabetes

K. Begay¹, S. Palmer², M. Coca², L. Hebert³, S. Stotz²

¹Maven Collective Consulting, Edmond, United States, ²Colorado State University, Food Science and Human Nutrition, Fort Collins, United States, ³Washington State University, Institute for Research and Education to Advance Community Health, Seattle, United States

Purpose: American Indian and Alaska Native (AI/AN) adults experience disproportionately high rates of type 2 diabetes (T2D) and face persistent barriers to accessing culturally relevant diabetes nutrition education. To address this gap, our team developed *What Can I Eat? Healthy Choices for AI/AN Adults with T2D* (WCIE) curriculum to reflect AI/AN strengths, cultural context, and traditional foodways. The WCIE Train-the-Trainer (TTT) Workshop was developed to build the capacity of AI/AN health professionals to deliver WCIE with fidelity.

Methods: Using a participatory and strengths-based approach, the team designed an interactive, two-day, in-person WCIE TTT format grounded in Adult Learning Theory that integrates flipped-classroom, teach-backs, storytelling, kinesthetic, and art-based learning strategies, offered at no cost to promote equitable access and community capacity building. Each WCIE TTT integrates local traditional foods, provides guidance for tailoring to honor the diversity of AI/AN communities, includes a scripted facilitator guide, and copies of all accompanying documents to initiate classes (e.g. participant guides). Evaluation data were compiled from workshop registration records and WCIE TTT feedback surveys.

Results: From 2021–present, 260 participants completed WCIE TTT workshops (n=11) in 8 U.S. states. Participants represented tribal and urban Indian clinics, Indian Health Service facilities, and community organizations. Over half (55%) worked in tribal clinics, and 29% were registered dietitian nutritionists. Participants (88%) rated the curriculum as highly applicable to their local context. Most rated the TTT workshop length “just right” (95%), reported high confidence teaching WCIE (56% very confident; 37% somewhat confident) and had strong intentions to implement the curriculum (46% very likely; 34% somewhat likely). Participants emphasized the TTT value of peer networking, hands-on learning, and leadership engagement, while identifying the need for ongoing technical assistance and refresher trainings (43% requested remote options).

Conclusion: WCIE TTT demonstrates a promising model for culturally tailored dissemination of diabetes nutrition education. Consistent with ISBNPA’s mission to promote innovative and impactful research in behavioral nutrition to improve global health and well-being, WCIE TTT exemplifies how culturally grounded training models can strengthen nutrition education capacity across diverse Indigenous communities. Future work will include longitudinal follow-up with trained facilitators and evaluation of WCIE implementation outcomes.

I-P-L.03

Randomized Trial of a Community Supported Agriculture Program to Reduce Chronic Disease Risk Factors Among Native Americans: The Go Healthy Study

V.B.B. Jernigan¹, K. Clyma¹, T. Taniguchi¹, K. Gabriel¹, J. Reese², Y. Zhang², S. Sisson³, T. Maudrie⁴, J. Hayman⁵, T. Jacob¹

¹Oklahoma State University Center for Health Sciences, Center for Indigenous Health Research and Policy, Tulsa, United States, ²University of Oklahoma, Department of Epidemiology and Biostatistics, Oklahoma City, United States, ³University of Oklahoma, Department of Nutrition Sciences, Oklahoma City, United States, ⁴University of Michigan, School of Social Work, Ann Arbor, United States, ⁵Osage Nation, Department of Natural Resources, Pawhuska, United States

Purpose: Native Americans (NAs) in the United States experience higher rates of diet-related diseases including obesity, diabetes, and heart disease, compared to other population groups. The Go Healthy randomized control trial (RCT) evaluated the efficacy of a reservation-based and culturally centered community supported agriculture (CSA) intervention to improve diet and reduce chronic disease risk factors among NA adults.

Methods: This 16-week RCT was implemented from January 2024 through June 2024 with 431 NA adults aged 18 years and older with a body mass index (BMI) ≥ 25 kg/m² living on the Osage Nation Indian reservation in Oklahoma. The RCT used a community-based participatory research approach and included the following components: 1) a weekly box of fresh produce from the Osage farm; 2) a healthy eating and traditional foods curriculum with recipes incorporating

L. INDIGENIZING WELLBEING RESEARCH

the produce; 3) cooking demonstration videos; and 4) a kitchen “starter kit” with basic cooking equipment. Data were collected at baseline and follow-up upon completion of the 16-week intervention. The primary outcomes were to improve systolic blood pressure (SBP) and blood serum lipids and increase fruit and vegetable intake. Secondary outcomes were to improve BMI, hemoglobin A1c (HbA1c), food security, and health status.

Results: At week 16, compared with the control group, the intervention group demonstrated statistically significant improvements in dietary consumption of fresh fruits and vegetables (+4.1 points (95% CI = 1.9, 6.3; $p < 0.001$)) and reduction in HbA1c (-0.35% (95% CI = -0.5, -0.2; $p < 0.001$)). Both groups saw an increase in food security. No statistically significant differences were observed in BMI, SBP, or blood lipids.

Conclusion: This is the first RCT of a CSA on a Native American reservation. Study findings show that a culturally centered CSA can be an effective approach to improve diet and reduce chronic disease risk factors among NAs. A CSA intervention can also address upstream causes of food insecurity and create sustainable solutions to support healthy food access.

I-P-L.04

Basketball, Healthy Community Identity, and the Role of ,Exercising‘ Sovereignty in One Montana Indigenous Community

A. Meyer¹

¹Baylor University, Health, Human Performance, and Recreation, Waco, United States

Purpose: This study examined perspectives from one Indigenous community (St. Ignatius, Montana) about the unique role and meaning high school basketball has in promoting communal adhesiveness and inclusivity. Themes emerged that speak to a variety of health outcomes for the wider community, including promoting physical activity broadly, addressing mental health concerns, and important intergenerational engagement. This study also intentionally sought to remove the researcher from the narrative, allowing the voice of community members to emerge.

Methods: Based on Grounded Theory, we conducted 3 separate focus group sessions. Community partners invited adults with various relationships to basketball. Community partners led recruitment efforts. 40 total community members participated across the 3 sessions. Questions were developed with community partner input, from scholarship on protective factors of ,exercising‘ sovereignty during Covid-19 (Ali-Joseph, A., *et al.*, 2023). Recordings were transcribed and coded for themes from relevant literature. *Strength’s Perspective* and *Abundance-based Approach*, two Indigenous health perspectives, were used in analysis. Themes were presented back to the community for input and approval. All materials were given to the Tribal Culture Committee.

Results: Unique to this study was the focus on community sport teams for approaching further health research questions among Indigenous communities. Four themes emerged. *Interdependence:* ,Everyone‘ has an important role when examining sport as a cultural health activity; *Tradition:* The importance of sport in a community’s history, story, and over generations; *Motivations:* Sport as a health behavior bellwether; *Influencers:* The variety of key community elements connected to sporting activities/events and individuals who play significant roles maintaining sport among Indigenous communities.

Conclusion: Gathering community members’ perspectives on one fundamental aspect of their life, high school basketball, had many participants in tears. No one had ever asked what basketball meant to them as a community. The significant meaning sport has for the collective identity of many Indigenous communities provides insights about who they are, what they value, and the various health outcomes and behaviors that can be accessed around it. This proposed poster highlights the importance of examining core Indigenous sport activities, central to communal identity, to better access and understand adjacent health behaviors and outcomes.

II-P-L.01

Understanding Caregiver Perspectives and Use of an Indigenized Meal Kit Provided in Healthy Eating and Physical Activity Programming for Youth

A. Crusan¹, A. Evans¹, A. Hanratty¹, K. Richards², K. Johnston-Goodstar³, A. Stately², M. Allen⁴

¹St. Catherine University, Nutrition & Dietetics, St. Paul, United States, ²Native American Community Clinic, Minneapolis, United States, ³University of Minnesota, Social Work, Minneapolis, United States, ⁴University of Minnesota, Family Medicine and Community Health, Minneapolis, United States

L. INDIGENIZING WELLBEING RESEARCH

Purpose: Family-centered approaches are crucial to address health disparities within Native American communities. Cardiovascular diseases are associated with poor food environments, making nutrition interventions a critical component to preventative models. Community-led research programs like Building Relationships Around Indigenous Endurance (BRAID) strengthen cultural identity and empower families through culturally-grounded innovations supporting healthy eating and physical activity for youth. This study explores families' use of Indigenized meal kits provided to youth participating in BRAID.

Methods: To date, 2 of 6 focus groups (n= 13) have been conducted with caregivers of youth participating in BRAID who received meal kits at two different programming locations. Remaining focus groups will occur in November and December 2025 following the same protocols. Semi-structured interviews were used to explore facilitators and barriers, modeled from Learning Circles promoting storytelling. Researchers independently coded the transcripts using a priori and emergent codes, ensuring cultural relevance while developing the coding tree, in the first review of outcomes (2 focus groups), and for the final interpretation of the data.

Results: Two focus groups (9 males, 4 females) revealed positive perspectives; however, caregivers' needs differed based on local program capacity. At a site where an Indigenous community organization provided meal kits, caregivers focused on facilitators such as family togetherness and connection to cultural foods. At a site with fewer established resources, more barriers emerged. While caregivers utilized all foods provided, they sought stronger alignment to Indigenous foods and more community engagement regarding food sovereignty. At both sites, caregivers identified needs for Indigenous language in resources and relationality with foods.

Conclusion: Families using Indigenized meal kits in healthy eating and physical activity programming for youth desired adaptations strengthening cultural connection via language embedded in resources provided with the kits, community involvement, and relationality with the food sources.

II-P-L.02

Advancing Indigenous-led Nutrition Education through Statewide Public Health Nutrition Programming in Colorado, USA

S. Stotz¹, J. Puma², K. Begay³

¹Colorado State University, Department of Food Science and Human Nutrition, Fort Collins, United States, ²University of Colorado, Anschutz Medical Campus, Denver, United States, ³Maven Collective Consulting LLC, Edmond, United States

Purpose: Since 2022, Colorado SNAP-Ed—the nutrition education component of the United States' Supplemental Nutrition Assistance Program (SNAP)—has implemented an initiative to fund and sustain Indigenous-led nutrition education across the state. Guided by the principles of Indigenous sovereignty and self-determination, this collaboration among Colorado State University, the Centers for American Indian and Alaska Native Health (CAIANH), the Rocky Mountain Prevention Research Center, and Maven Collective Consulting aims to ensure that SNAP-Ed resources are equitably accessible and responsive to the priorities of Indigenous communities.

Methods: Through a competitive subaward process, funding was provided to three American Indian- and Indigenous-serving organizations annually between 2022 and 2025. Each organization designed and delivered culturally grounded nutrition education rooted in traditional foods, local agriculture, and community priorities. The project team provided technical assistance, evaluation training, and advocacy to promote Indigenous-led activities as “allowable costs” under USDA SNAP-Ed guidelines. Mixed-methods evaluation included interviews, observation of program delivery, and documentation of policy and systems-level changes.

Results: Across three funding cycles, nine subawards were granted, including sustained funding for one urban (Denver) and 2 rural-based organizations in southwest Colorado. Activities included Indigenous chef-led workshops, youth mentorships in traditional agriculture, and culturally tailored food literacy programming. Evaluation findings indicate strengthened community capacity, increased integration of traditional food knowledge, and enhanced visibility of Indigenous leadership within state nutrition networks. The initiative culminated in presentations at national conferences advancing advocacy for policy recognition of Indigenous-led education.

Conclusion: Despite recent federal SNAP-Ed defunding in the United States, this initiative stands as a powerful model for embedding Indigenous leadership, sovereignty, and cultural knowledge at the core of public health nutrition systems. The partnerships, evidence, and policy advocacy it generated continue to shape state and national dialogues, calling for sustained investment in Indigenous-designed and -led nutrition education as a pathway to food sovereignty and community wellbeing.

II-P-L.03

Strengthening Indigenous Food Sovereignty through GusNIP-supported Produce Prescription and Nutrition Incentive Programs

K. Begay¹, S. Stotz², C. Byker Shanks³, A. Yaroch³

¹Maven Collective Consulting LLC, Edmond, United States, ²Colorado State University, Fort Collins, United States, ³Center for Nutrition & Health Impact, Omaha, United States

Purpose: The United States Department of Agriculture's Gus Schumacher Nutrition Incentive Program (GusNIP) funds produce prescription (PPR) and nutrition incentive (NI) programs to increase access to fruits and vegetables. Across the United States, Indigenous-led and Indigenous-serving organizations implement GusNIP-supported programs that align federal nutrition support with community-defined priorities for food sovereignty, cultural foodways, and wellness. These organizations bring deep place-based knowledge and trusted relationships while also navigating considerations related to Tribal governance, data sovereignty, and culturally grounded evaluation. This presentation highlights how GusNIP programs are adapted in Indigenous contexts and how peer-learning approaches support community-driven implementation.

Methods: Insights were generated through collaboration among Indigenous-serving grantees and the GusNIP Nutrition Incentive Program Training, Technical Assistance, Evaluation, and Information Center (NTAE), along with peer-learning activities. A key approach, the GusNIP Indigenous Learning Circle (ILC), convenes Indigenous-led and Indigenous-serving organizations for quarterly sessions grounded in Indigenous methodologies and relational accountability. Sessions feature community-led presentations, strategies for sourcing culturally relevant foods, discussion of Tribal IRB and data governance processes, and exchange of culturally aligned evaluation tools. Technical assistance materials and evaluation data (e.g., notes, surveys, site data) inform understanding of changes in capacity, collaboration, and confidence in program adaptation.

Results: GusNIP supports a growing network of Indigenous-serving programs across Tribal health departments, urban Indian health clinics, and community-based food sovereignty organizations. Successful implementation is rooted in long-standing relationships, Tribal decision-making authority, and alignment of program goals with cultural foodways and community wellness. Grantees report adapting PPR and NI models to procure from Tribal growers, incorporate traditional and seasonal foods, and apply Indigenous-led evaluation frameworks. The ILC has connected more than 20 organizations across 15 states in the U.S., strengthening shared learning and increasing confidence in navigating Tribal IRB review, data sovereignty considerations, and community-centered evaluation methods.

Conclusion: When guided by Indigenous leadership and community priorities, GusNIP programming advances food sovereignty in ways that are relational, culturally grounded, and sustainable. Peer-learning models such as the ILC build collaboration and demonstrate how national nutrition programs across the U.S. can partner authentically with Indigenous communities while honoring sovereignty and community-defined success.

II-P-L.04

Growing Older Staying Strong: A CBPR Collaborative to Promote Physical Activity and Healthy Longevity among Native American Older Adults Living on the Flathead Indian Reservation

S. Morigeau¹, H. Adams¹, T. Stewart², N. Graham², A. Manuel², A. Akers¹, J. Knoll¹, L. Caldbeck¹, J. Krumbeck¹, C. Kleinmeyer¹, M. Pedersen²

¹Confederated Salish and Kootenai Tribes, Tribal Health Department, Ronan, Montana, United States, ²University of Montana, School of Public and Community Health, Missoula, United States

Purpose: American Indian and Alaska Native (AIAN) older adults are more likely to experience a fall-related injury than the U.S. national average, yet implementation of physical activity (PA)-based fall prevention interventions in AIAN communities has been limited. High rates of fall-related injury and death among this population can be mapped to the longstanding negative sequelae of colonization enacted by the U.S. government, including land dispossession, forced relocation, and disruption of traditional food and cultural practices. Yet AIAN older adults have demonstrated deep resilience and adaptability across generations of rapid social and environmental change, and today stand to benefit greatly from opportunities to increase PA, reduce risk of falls, and extend healthy longevity. The purpose of the study is to use a community-based participatory research (CBPR) approach to promote healthy longevity among AIAN older adults living on the Flathead Indian Reservation through attentive, inclusive implementation of evidence-

L. INDIGENIZING WELLBEING RESEARCH

based PA interventions.

Methods: The CBPR collaboration between the Confederated Salish and Kootenai Tribes (CSKT) of the Flathead Reservation and the University of Montana started in 2018 and continues today. This study applied a concurrent mixed methods design using post-test qualitative focus groups and pre-post survey and performance measures. The Iterative Adaptation Process (Ivanich et al., 2020) was applied to select, adapt, and evaluate evidence-based interventions to match the priorities of community members. In particular, the research is grounded in the concept of PA security (Lambert et al., 2020).

Results: We will present a concurrent mixed method evaluation with side-by-side presentation of intervention outcomes among AIAN older adults living on the Flathead Reservation. Qualitative results (N= 60 to-date) are presented across PA security domains, which informs and provides critical community voice and context to a RE-AIM-based implementation evaluation (N=220 participants) across six CSKT communities.

Conclusion: This is an exemplary tribally-drive CBPR study, where research practices are embedded within the priorities of the community, and a long-term commitment is present among partners. Outcomes indicate positive change in PA security across multiple levels of community health, suggesting promise for improved PA levels and healthy longevity among AIAN older adults.

II-P-L.05

Ripple Effects Mapping to Develop a Multilevel Community-Based Fall Prevention Intervention among Rural Native American Older Adults

M. Pedersen¹, S. Morigeau², E. Christiansen¹, H. Adams², T. Stewart¹, N. Graham¹, A. Manuel¹, J. Knoll¹, L. Caldbeck², J. Krumbeck², C. Kleinmeyer²

¹University of Montana, School of Public and Community Health, Missoula, United States, ²Confederated Salish and Kootenai Tribes, Tribal Health Department, Ronan, Montana, United States

Purpose: Falls are a leading cause of injury-related disability and death among older adults worldwide, and in the U.S., American Indian and Alaska Native (AIAN) older adults experience pronounced fall-related health disparities. The purpose of this study was to use a community-based participatory research (CBPR) approach to identify multilevel impacts of a physical activity-based fall prevention intervention implemented by a rural, tribal health organization.

Methods: Ripple effects mapping (REM) is a systematic, participatory, qualitative group method that can generate contextualized, community-driven perspectives on intended and unintended impacts of public health efforts. A CBPR approach and REM were used to examine multilevel impacts of an evidence-based physical activity (PA) and fall prevention intervention (Stay Active and Independent for Life) implemented by the Confederated Salish and Kootenai Tribes (CSKT) Tribal Health from 2023-present. Members of the CSKT Tribal Health implementation personnel and CBPR study team were recruited to participate in the 4-step REM process. The REM process was conducted across two 2-hour group sessions, with follow-up sessions to conduct member checking of thematic findings.

Results: Participants (N=12) were CSKT Tribal Health personnel (75%) and CBPR study team members (25%). A preliminary analysis using the 4-step REM process yielded eight primary themes, 12 secondary themes, and 38 corresponding tertiary themes. Themes were visually documented and organized using a digital mapping tool (Xmind, 2026). Primary themes were present across multiple socio-ecological levels, including individual (knowledge sharing, improved health), social (social connectedness), organizational (staff growth, challenges with implementation), and environmental/policy levels (scale and retention, resources and collaboration). All findings will be presented in the REM visual representation.

Conclusion: This study used a CBPR approach to advance understanding of potential targets for the development of a multilevel PA promotion intervention to reduce fall risk among rural AIAN communities in the U.S. Results provide contextualized, community-driven perspectives, which are of critical importance in tribally driven intervention development. Findings will be used to inform the next steps of this research, which are to co-develop and conduct a hybrid implementation effectiveness study to test implementation of a multilevel fall prevention intervention.

Systems Models in Food Is Medicine: Mediterranean Diet Quality Improves during Pregnancy

L. Bailey Davis^{1,2}, K. Herb Neff^{1,2}, GC. Wood², K. Brandt³, K.A Marshall⁴, AD. Mackeen⁵, L. Wright², S. Lutcher^{2,1}, C.J Seiler^{2,1}, A.R Chang¹

¹Geisinger College of Health Sciences, Population Health Sciences, Danville, United States, ²Geisinger College of Health Sciences, Center for Women's and Children's Research, Danville, United States, ³Family Health Council of Central Pennsylvania, Camp Hill, United States, ⁴Geisinger College of Health Sciences, Emergency Medicine, Danville, United States, ⁵Geisinger College of Health Sciences, Maternal-Fetal Medicine, Danville, United States

Purpose: System models that combine prenatal care with food provision in the social sector and/or nutrition education via telehealth may better support dietary quality beyond prenatal care alone. Changes in diet quality during pregnancy were examined by varied models.

Methods: A randomized controlled trial at Geisinger Health (Pennsylvania, USA) in 2024 enrolled pregnant patients with household income <185% federal poverty level. Participants were randomly assigned to models: Clinic (usual prenatal care); Clinic-WIC (referral to the Special Supplemental Nutrition Program for Women, Infants and Children); Clinic-RDN (referral to Registered Dietitian/Nutritionist); Clinic-WIC-RDN. Self-reported diet quality was assessed by study questionnaire using the Mediterranean Eating Patterns for Americans (MEPA). Changes in MEPA score and adherence (>8) from baseline to 6-month follow-up and across models were compared. Repeated measures regression was used to estimate changes within each model and to compare across models. Trial Registration: NCT06311799.

Results: Among 240 participants, the mean (Standard Deviation [SD]) age was 29.2 (6.1) years, 65% were white, 14% black, and 12% Hispanic. Mean pre-pregnancy body mass index was 30.4 (8.4) kg/m² and participants enrolled at 17+6 weeks gestation. There were no differences in MEPA scores or adherence across the models at baseline: Clinic model 6.7 (2.3), 36% adherent; Clinic-WIC model 6.8 (2.3), 36% adherent; Clinic-RDN model 7.5 (2.3), 45% adherent; Clinic-WIC-RDN model 7.2 (2.3), 42% adherent. At 6-month follow-up, participants in most models experienced improvements in MEPA scores and adherence, but there were no statistically significant differences between models for MEPA outcomes. The absolute difference in MEPA scores from baseline to 6-month follow-up in the Clinic model was +0.52 (2.50); Clinic-WIC model was +0.75 (2.15; p<0.05); Clinic-RDN model was -0.04 (2.24); Clinic-WIC-RDN model was +0.70 (2.36). At 6-month follow-up, improved adherence to MEPA in the Clinic model was +4.2%; Clinic-WIC model was +14.6%; Clinic-RDN model was +9.9%; and Clinic-WIC-RDN model was +15.9%.

Conclusion: Pregnant women improved adherence to the Mediterranean Eating Pattern for Americans by two- or three-fold when exposed to models that leveraged systems approaches to connect health care, social care with food provision, and education. Future research is needed with larger sample sizes for statistical power and subgroup analyses.

I-P-M.02

The Perceptions of South African Dietetic and Nutrition Professionals on the Sponsorship and Funding of Scientific Education Opportunities by Big Food

T.K. Scorgie¹, L.M. du Plessis¹, J. Badham²

¹Stellenbosch University, Human Nutrition, Cape Town, South Africa, ²JB Consultancy, Johannesburg, South Africa

Purpose: Dietetic and nutrition professionals have gained greater access to evidence-based information sessions, networking opportunities and collaborative practice. This, however, provides Big Food with opportunities to sponsor and fund scientific education events, which in turn could influence nutrition research, collaboration, policy, and practice whilst simultaneously building brand loyalty. The aim of this study is to determine the perceptions of South African dietetic and nutrition professionals on the sponsorship and funding of scientific education opportunities by Big Food.

Methods: Members of the Association for Dietetics in South Africa (ADSA), the Nutrition Society of South Africa (NSSA), and the Dietetics-Nutrition is a Profession (DIP) groups (excluding students) were invited to participate in an online survey using census and snowball sampling. The online survey used a Likert scale to record participants' responses to experience and perception questions and included a short demographic section. In addition, dietetic/nutrition professionals were recruited for semi-structured interviews using purposive sampling. A semi structured interview guide with open-ended and probing questions, where necessary, was used.

M. SYSTEMS SCIENCE

Results: Dietetic and nutrition professionals hold varied and contentious views on Big Food sponsorship of scientific education opportunities. Some participants support collaboration to modify the nutritional content of unhealthy products to healthier options, while others strongly oppose it, citing conflicts between commercial interests and public health goals. Concerns regarding conflicts of interest (COI) in scientific education opportunities emphasises the need to protect scientific credibility and integrity.

Conclusion: Participant's perceptions emphasise the diverse and complex nature of public private partnerships (PPPs) and highlight the importance of consensus guidelines to ensure ethical interaction. Well-defined disclosure and transparency measures that work synergistically within a broader food systems approach are recognised as central to achieving improved nutrition outcomes through COI-free scientific education opportunities.

I-P-M.03

The Development of a Conceptual Framework for Nutritional Psychology

N. Stroebele-Benschop¹, V. Hedrih², S. Behairy³, E. Morpheq-Lu³

¹University of Hohenheim, Department of Applied Nutritional Psychology, Stuttgart, Germany, ²University of Niš, Niš, Serbia, ³Center for Nutritional Psychology, San José, United States

Purpose: One's psychological state can affect what, where, and how much one eats, and eating influences psychological wellbeing through a wide range of affective, cognitive, perceptual, interoceptive, and environmental processes. Many recent discoveries highlight a bidirectional link between nutrition and psychological processes. Despite these developments, the systematic study of this connection is only just emerging and nutritional psychology is not yet recognized as a formal area of study within the behavioral, psychological or nutritional sciences. This work aims to organize existing evidence into a structured conceptual framework that outlines the key domains of nutritional psychology and situates the field among adjacent disciplines.

Methods: Scientific publications on the connections between nutrition and psychological processes were compiled, reviewed, curated, and classified in a research library comprising over 3,000 publications. Key concepts were extracted, synthesized, grouped, and iteratively reviewed using a structured conceptual framework approach. The conceptualization of the framework is continuously being refined.

Results: The current framework includes six core areas of nutritional psychology: Nutrition-Conation/Affect Relationship, Nutrition-Cognition Relationship, Nutrition-Sensory Perception Relationship, Nutrition-Interoceptive Relationship, Nutrition-Psychosocial Relationship, Nutrition-Environment Relationship. These areas illustrate distinct aspects of the nutrition-psychology relationship and provide an organizing structure for conceptualizing nutritional psychology as a field of study.

Conclusion: To advance our understanding of how nutrition and psychology interconnect, the authors introduce six core areas that define the scope of nutritional psychology. By offering a conceptual framework, this work provides a theoretical foundation that can guide future research, education, and practice in this emerging interdisciplinary scientific field.

I-P-M.04

Inequities in the Availability of School-based Physical Activity Facilities in Brazil: Urban-rural Differences and the Role of Exclusive Provision for Students with Disabilities

C.F. Silva¹, L. Gonçalves¹, D.A.S. Silva¹

¹Federal University of Santa Catarina, Department of Physical Education, Florianópolis, Brazil

Purpose: The availability of adequate spaces for school-based physical activity (PA) is a determinant of healthy lifestyles and equity, particularly in contexts marked by territorial and inclusion-related inequalities. This study aimed to quantify the availability of PA-related physical structures in Brazilian schools and to examine how it varies by area of location (urban vs. rural), by the presence of exclusive educational provision for students with disabilities (yes vs. no), and by the intersection of these factors.

Methods: Cross-sectional analysis of the 2024 Brazilian School Census completed by school principals/administrators via a standardized questionnaire. The unit of analysis was the school (n = 177,067 Basic Education schools nationwide), of which 174,057 did not have exclusive classes for students with disabilities and 3,010 did. Across all schools, we

M. SYSTEMS SCIENCE

assessed the presence of the following PA-related structures: covered courtyard, uncovered courtyard, playground, swimming pool, sports court, dance studio, and “terreiro” (i.e., an open dirt playfield, uncovered, unpaved, with no built structures). Analyses considered area of location, exclusive-service status, and their intersection. Pearson’s chi-square test was used with a significance level of 5%.

Results: Overall, 86.1% of schools had at least one PA structure, with higher prevalence in urban than rural areas (93.3% vs. 67.6%, $p < 0.01$) and in schools providing exclusive services for students with disabilities compared with those that did not (95% vs. 86%, $p < 0.01$). In the intersectional analysis, rural schools without exclusive classes for students with disabilities showed the highest proportion lacking any PA structure (32.4%; $p < 0.01$) relative to other subgroups.

Conclusion: Despite broad overall availability, pronounced inequities persist by geographic location and disability-service status, underscoring the need for targeted, intersectoral investments in PA infrastructure, especially in rural school networks, to advance equity and expand access to safe, diverse PA spaces, with likely spillover benefits for whole-of-school health promotion.

Purpose: This study provides a comprehensive mapping of qualitative research on physical activity and health across the Americas. We aimed to quantify the proportion of qualitative studies within the broader literature, identify countries contributing to this work, and examine the populations and thematic areas addressed.

Methods: An updated systematic review conducted by the Global Observatory for Physical Activity (GoPA!) (PROSPERO: CRD42017070153) of peer reviewed articles on physical activity and health in the Americas was conducted using a predefined search strategy across major databases for the period 2020 to 2023. Studies were screened using standardized inclusion criteria and classified by design. Data extraction included country, population group, study focus, and topic. Descriptive statistics were calculated to determine proportional distribution. Categorization of study focus and topic areas was conducted using a the standardized GoPA! methodology. Analyses were performed in Stata.

Results: Of 2,640 included articles extracted from the Americas, 197 (7.5%) used qualitative methods. Production was highly concentrated in the United States (37.6%) and Canada (33.0%), followed by Mexico (7.6%) and Brazil (6.6%). Several countries contributed only one study. Nearly half of qualitative studies included multiple age groups (45.2%), while adults were included in 23.4%, children and adolescents in 14.2%, older adults in 9.6%, and pregnant women in 3.6%. The most common study focus was correlates and determinants of physical activity (38.6%), followed by interventions (24.4%) and policy and practice (18.8%). Frequently addressed topics included healthy lifestyles (11.7%), cancer (9.6%), physical activity and nutrition (9.1%), and disability (8.1%), whereas environmental and sustainability related topics were rare.

Conclusion: Qualitative research represents a small fraction of physical activity scholarship in the Americas and is concentrated in few countries and selected topics. Expanding qualitative capacity across underrepresented regions and populations may strengthen culturally grounded evidence, enhance implementation relevance, and advance equitable knowledge production in behavioral physical activity research.

Using Participatory Systems Mapping to Address the Mental Health of Adolescents Growing up in Poverty

N. de Pooter¹, I. Koopmanschap¹, M. Peeters¹, M. Nicolaou², L. Shields-Zeeman³, G. Stevens¹, C. Kamphuis¹

¹Utrecht University, Utrecht, Netherlands, ²Amsterdam UMC, Amsterdam, Netherlands, ³Trimbos-Institute, Utrecht, Netherlands

Purpose: It is largely acknowledged that adolescents growing up in poverty have poorer mental health outcomes, but much remains unknown about the underlying complex interplay of factors and mechanisms. Acknowledging and addressing this complexity is vital for effective intervention. This study aimed to provide insight into the mechanisms underlying the mental health of adolescents growing up in poverty according to different stakeholders and to identify leverage points to improve adolescent mental health.

Methods: To collect this information, we organized four rounds of Group Model Building (GMB) workshops with adolescents, parents, professionals and policymakers in two neighborhoods in the Netherlands. GMB is a qualitative method that engages diverse stakeholders to collectively consider causes and possible solutions of complex problems, visualizing this in a systems map.

Results: Participants reported that growing up in poverty impacts adolescent mental health through (1) being able to fit in with peers, (2) spending free time outside, (3) stress caused by multiple factors, and (4) feeling unfairly treated at school. As part of these subsystems, ten leverage points were identified that could offer pathways to enhance adolescent mental health.

Conclusion: Our findings demonstrate that adolescents growing up in poverty experience mental health challenges due to various social processes and structural deficiencies. Effectively addressing adolescent mental health requires a fundamental shift in how they are perceived by the community around them while simultaneously improving families' financial and living conditions. A comprehensive systems approach is needed for lasting impact, combining interventions with immediate effects, structural reforms and socio-cultural change.

II-P-M.02

Using Systems Archetypes to Understand System Behaviour and Identify Leverage Points for Change in Local Obesity Prevention in the Netherlands

J. O'Mara¹, L. Crielaard¹, L. Hagenars¹, K. Stronks¹, W. Waterlander¹

¹AmsterdamUMC, Public and Occupational Health, Amsterdam, Netherlands

Purpose: Participatory system dynamics (SD) approaches view public health problems as the result of a complex system of interactions. However, most public health research makes a direct leap from system mapping –often through causal loop diagrams (CLDs)- to identifying actions for change, without trying to understand the behaviour of the system as a whole and how actions could intervene. This is possibly because robust methods are lacking. This study aimed to explore whether 'systems archetypes' can bridge this gap to (1) better understand system behaviour, (2) identify leverage points (LPs) for change deeper in the system and (3) provide a more structured and traceable analysis.

Methods: We developed a novel approach using 11 generally accepted systems archetypes to perform a post hoc analysis of the eight mechanisms derived from the LIKE Project – a participatory SD project on childhood obesity prevention in Amsterdam, the Netherlands. For each LIKE mechanism we compiled a complete archetype profile, including the storyline, CLD and behaviour (graph) over time (GoT). We analysed qualitative and quantitative data to cross-check two GoTs. Finally, we reflected on this process compared with the participatory method used in the LIKE project.

Results: We identified six systems archetypes, which helped us understand the behaviour of the system. The most common was 'fixes that fail', which shows how a 'fix' applied to a problem can create unintended consequences that reinforce the problem. This can lead to 'shifting the burden' in which resources are siphoned from addressing the root cause of the problem. Compared with the originally derived points, we identified LPs deeper in the system at the paradigm and goals levels according to the Intervention Level Framework (ILF). Systems archetypes structured the process of analysis, which limited researcher interpretation and improved reproducibility and traceability.

Conclusion: Our findings suggest that systems archetypes should be added to the SD toolbox for researchers and practitioners. They can help hypothesize about a system's behaviour and lead to novel and more refined insights into how a system works and how its behaviour could be changed.

M. SYSTEMS SCIENCE

II-P-M.05

Is Cardiorespiratory Fitness Protective Against Low-grade Inflammation in Paralympic Athletes with a Locomotor Impairment?

A. Ciccarelli¹, I. Peluso², G. Pugliese¹, M.R. Squeo³, G. Di Gioia³, E. Poggiogalle⁴, M. Bernardi¹

¹“Sapienza” University of Rome, Department of Physiology and Pharmacology, “V. Erspamer”, Rome, Italy, ²Council for Agricultural Research and Economics (CREA-AN), Research Centre for Food and Nutrition, Rome, Italy, ³Institute of Sports Medicine and Science - Italian National Olympic Committee, Rome, Italy, ⁴“Sapienza” University of Rome, Department of Experimental Medicine Medical Pathophysiology, Food Science and Endocrinology Section Food Science and Human Nutrition Research Unit, Rome, Italy

Purpose: Low-grade chronic inflammation (LGCI), closely associated with atherosclerotic cardiovascular disease (ACVD), is a major contributor to chronic non-communicable diseases (1). Individuals with spinal cord injury (SCI), characterized by neurogenic obesity, sedentary lifestyle and low VO₂peak, have increased ACVD risk compared to able-bodied people (2). Rosety-Rodriguez et al showed that arm-cranking ergometer training improves VO₂peak and reduces LGCI in SCI (3). Nevertheless, LGCI is prevalent in Paralympic athletes (PA) with motor impairment (4), despite high VO₂peak. This study hypothesizes an inverse association between VO₂peak and LGCI in PA from different sports and with different health conditions (HC).

Methods: Data from 153 male PA (82 with SCI, 71 with other HC) recruited during pre-participation screenings (5) before Summer and Winter Paralympic Games were retrospectively analysed. Athletes competed in skilled (SS, n=38), power (PS, n=28), mixed (MS, n=61) and endurance sports (ES, n=26). Inflammation status was assessed by the neutrophil-to-lymphocyte ratio (NLR) from blood samples as a surrogate of LGCI (6). VO₂peak (ml·kg⁻¹·min⁻¹) was measured by incremental maximal cardiopulmonary exercise testing (Quark CPET, Cosmed). Group differences were analysed with Kruskal–Wallis test, and Spearman correlation evaluated the association between VO₂peak and NLR.

Results: Median NLR values (and ranges) didn't show statistic differences among PA competing in the different sport types: 1.7 (0.7-3.8) in SS, 1.6 (0.9-3.2) in PS, 1.6 (0.9-4.1) in MS and 1.4 (0.9-2.7) in ES. Also VO₂peak didn't show statistic differences in the 4 types of sports: 23.9 (15.2-39.7) in SS; 32.4 (17.1-50.8) in PS; 33.3 (16.4-44.7) in MS and 43.1 (27.5-58.1). A linear regression analysis showed a negative correlation between VO₂peak and NLR ($r = -0.208$; $p = 0.009$).

Conclusion: In these PA, NLR and VO₂peak did not differ among the sport types. However, the inverse relationship between VO₂peak and NLR indicates that lower cardiorespiratory fitness is modestly but significantly linked to LGCI, regardless of sport. These findings suggest that aerobic fitness, rather than sport type, may influence inflammatory status.

II-P-M.07

Higher Low-carbohydrate Diet Score is Associated with Lower Cardiovascular Mortality in Korean Adults

J. Youn¹, K.W. Nam¹, S. Shin¹

¹Chung-Ang University, Department of Food and Nutrition, Gyeonggi-do, Korea, Republic of

Purpose: Evidence on the long-term health effects of low-carbohydrate diets remains inconsistent, particularly in populations with traditionally high carbohydrate intake such as Korea. This study aimed to examine the association between the low-carbohydrate diet score (LCDS) and all-cause and cause-specific mortality, including cancer, cardiovascular disease, and chronic respiratory disease among Korean adults.

Methods: We analyzed data from 7,303 participants aged 40–69 years from the Korean Genome and Epidemiology Study. Dietary intake was assessed using a validated food frequency questionnaire, and the LCDS was derived by assigning scores based on the percentages of energy intake from carbohydrates, proteins, and fats, with higher scores reflecting lower carbohydrate and higher protein and fat intake. Mortality was ascertained using national death records from the Ministry of Data and Statistics. Multivariable-adjusted Cox proportional hazards models were used to estimate hazard ratios (HRs) and 95% confidence intervals (CIs) for all-cause, cancer, cardiovascular disease, and chronic respiratory disease mortality in the overall population, with analyses further stratified by sex.

Results: During a mean follow-up of 21.0 years, 1,020 deaths were documented, including 334 from cancer, 231 from cardiovascular disease, and 129 from chronic respiratory disease. Participants in the highest quintile of LCDS had a significantly lower risk of CVD mortality compared with those in the lowest quintile (HR: 0.60, 95% CI: 0.37–0.98; P for trend = 0.01). In sex-stratified analyses, men in the third quartile of LCDS had a significantly lower risk of CVD mortality

M. SYSTEMS SCIENCE

compared with those in the lowest quartile (HR: 0.50, 95% CI: 0.27–0.95). In women, higher LCDS was borderline associated with lower CVD mortality (HR: 0.54, 95% CI: 0.27–1.10; P for trend = 0.06). LCDS was not significantly associated with all-cause, cancer, or CRD mortality.

Conclusion: Higher LCDS was associated with lower CVD mortality among Korean adults, whereas no significant associations were observed for other mortality outcomes. These findings suggest that macronutrient composition, specifically lower carbohydrate intake, may be relevant to cardiovascular mortality risk in populations with traditionally high carbohydrate intake.

Examining How Sources of Sociocultural Appearance Pressures Relate to Dysfunctional and Intuitive Eating among Pregnant Women: A Latent Profile Analysis

M. Plouffe^{1,2}, A.-F. Tessier^{1,3}, M.-F. Beaudin^{1,2}, M.-P. Gagnon-Girouard^{1,2}, A.-S. Morisset^{2,4}, É. Carbonneau^{2,5}, F.-A. Guimond⁶, C. Maïano⁷, G. Lavigne¹, N. Carbonneau^{1,2}

¹Université du Québec à Trois-Rivières, Psychology, Trois-Rivières, Canada, ²Institute of Nutrition and Functional Foods (INAF), Québec, Canada, ³Institute of Nutrition and Functional Foods (INAF), Quebec, Canada, ⁴Université Laval, Nutrition, Québec, Canada, ⁵Université Laval, Québec, Canada, ⁶Université d'Ottawa, Psychology, Ottawa, Canada, ⁷Université du Québec en Outaouais, Psychology, Québec, Canada

Purpose: Women are exposed to multiple sociocultural appearance pressures (i.e., societal expectations concerning body weight and shape), and pregnancy is no exception to this reality. The present study aimed to (1) identify latent profiles of pregnant women based on their perceived sociocultural appearance pressures from multiple sources, and (2) examine how profile membership was associated with intuitive eating (i.e., eating without rigid rules in response to internal hunger and satiety cues), restrained eating (i.e., deliberate restriction of food intake to control body weight/shape), external eating (i.e., eating in response to external food cues), and emotional eating (i.e., eating in response to negative emotions).

Methods: In this study, 250 pregnant women aged 25 to 40 years ($M = 32$) in their third trimester completed an online questionnaire assessing sociocultural appearance pressures (Sociocultural Attitudes Toward Appearance Questionnaire), intuitive eating (Intuitive Eating Scale), and dysfunctional eating behaviors (Dutch Eating Behaviour Questionnaire). A latent profile analysis (LPA) using robust maximum likelihood estimation in Mplus tested two- to four-profile models based on five indicators of perceived appearance pressures: from romantic partners, family, friends, healthcare professionals, and media.

Results: The three-profile solution provided the best statistical and theoretical fit. The profiles reflected (a) low pressure from all sources (60.3%), (b) moderate pressure from all sources (30.3%), and (c) high peer- and family-related pressure (9.4%). One-way ANOVAs revealed that intuitive, restrained, and emotional eating (but not external eating) differed significantly across profiles ($ps < .01$). Specifically, participants in the low-pressure profile reported the lowest levels of restrained eating and the highest levels of intuitive eating compared to the two other profiles, which did not differ significantly from each other. In addition, participants in the low-pressure profile reported significantly lower levels of emotional eating than those in the high-pressure profile, whereas participants in the moderate-pressure profile did not differ significantly from either of the other two profiles.

Conclusion: This study highlights the varied sociocultural appearance pressures experienced by pregnant women and their associations with eating behaviors. The findings underscore the heterogeneity of these experiences and provide insights into potential risk and protective factors related to eating during pregnancy.

I-P-N.03

Impact of Judo Training on Functional Capacity in Youth with Intellectual Disabilities

O. Ortiz-Castejón¹, A. Nieto-Guisado¹, M. Moragas-Rovira¹, M. Guerra-Balic¹, M.A. Gómez-Hinojosa¹, V. Riera¹, J. Morales¹

¹Facultat de Psicologia, Ciències de l'Educació i l'Esport. Blanquerna-URL, Barcelona, Spain

Purpose: The objective was to evaluate the impact of an adapted judo program on functional capacity in youth with intellectual disabilities (ID), specifically focusing on the 6-Minute Walk Test (6MWT). The study compared pre- and post-intervention changes between an experimental group, which participated in the judo program, and a control group.

Methods: The sample included 23 participants, comprising 9 girls and 14 boys, with a mean age of 14.1 years ($SD = 1.52$). The experimental group consisted of 16 participants, while the control group included 7 participants. On average, participants in the sample had a height of 158.3 cm ($SD = 12.13$), weight of 57.1 kg ($SD = 13.59$), and waist circumference of 68.3 cm ($SD = 11.77$). A pre-post design with a control group was implemented. The primary analysis utilized a linear mixed model to examine the effects of Group (Control/Experimental), Time (Pre/Post), and their interaction (Group $\times$ Time) on the 6MWT results. A random intercept for each participant was included in the model to

N. MENTAL HEALTH AND WELLBEING

account for individual variation. Estimated marginal means (EMMs) with 95% confidence intervals (CIs) and two-tailed p-values ($\alpha = 0.05$) were reported. Normality assumptions were verified using Q-Q and residual plots. All statistical analyses were performed using Jamovi v 2.5.5 (GAMLj module).

Results: The results revealed a significant Group $\times$ Time interaction ($p = 0.008$), indicating that the experimental group experienced a greater improvement in walking capacity compared to the control group. The control group showed minimal change in walking distance, with a pre-test score of 408 meters and a post-test score of 406 meters. In contrast, the experimental group demonstrated a significant improvement, increasing from 475 meters at pre-test to 498 meters at post-test. The estimated difference between the groups in post-intervention change was +25 meters (95% CI [7.9, 42.0], $p = 0.008$). Assumption checks confirmed the normality of residuals (Shapiro-Wilk = 0.981, $p = 0.661$).

Conclusion: The adapted judo program significantly improved walking capacity in the 6MWT, compared to the control group. These findings support the use of adapted judo as an effective physical activity to enhance functional fitness in adolescents and young individuals with intellectual disabilities.

I-P-N.04

Combined Effects of Physical Activity and Sedentary Behavior on Subjective Well-being: Insights from a German Population Study

B. Wallmann-Sperlich¹, L. Kummert¹, B. Biallas², I. Froboese²

¹Julius-Maximilians-University Wuerzburg, Integrative & Experimental Exercise Science and Training, Institute of Sport Science, Faculty of Human Science, Wuerzburg, Germany, ²German Sport University Cologne, Institute of Movement Therapy and Movement-oriented Prevention and Rehabilitation, Cologne, Germany

Purpose: Regular physical activity (PA) benefits mental and social health, contributing to overall subjective well-being (SWB), whereas sedentary behavior (SB) is linked to lower SWB independent of PA. However, the joint effects of PA and SB, and the differential impact of PA domains, remain poorly understood. This study examined associations of PA, sitting time, and their combined behavioral patterns with SWB among German adults, considering physical activity domains as work, transport, and leisure.

Methods: Data were drawn from a nationally representative 2023 telephone survey ($N = 2,753$; 46.8% men; mean age = 53.0 ± 16.6 years). PA was assessed across work, transport, and leisure using the Global Physical Activity Questionnaire, sitting time via the Marshall Sitting Questionnaire. SWB was measured with the WHO-Five Well-Being Index. Multiple linear regression models adjusted for sociodemographic and health-related covariates examined domain-specific PA, sitting time, and combined behavior patterns in relation to SWB.

Results: Overall SWB averaged 62.0 (SD = 22.6), with 25.9% of participants scoring ≤ 50 . Men, older adults, and those with better self-rated health reported higher SWB. Work-related PA and sitting time were negatively associated with SWB, whereas transport- and leisure-related PA were positively associated. Participants with lower sitting (< 8 h/weekday) and sufficient transport- or leisure-related PA (≥ 600 MET-min/week) exhibited the highest SWB ($B = 7.17$, $p < .001$), followed by high-sitting/sufficient PA individuals, relative to the reference group of higher sitting (> 8 h/weekday) and insufficient transport- or leisure-related PA (< 600 MET-min/week).

Conclusion: Leisure- and transport-related PA positively predicted SWB, while work-related PA and prolonged sitting were detrimental. Volitional PA appears to offset the negative impact of high sitting for SWB, emphasizing the need for domain-specific strategies that promote active lifestyles and reduce sedentary behavior to enhance population well-being.

I-P-N.05

The Benefits of Nature on Positive Youth Development: Evidence from the Nova Scotia Youth, Nature, and Wellbeing Survey

M. Kwan¹, S. Truong¹, J. Campbell¹, S. Pawelko¹, A. Cohen¹, J. Cawley¹, M. Stone¹

¹Dalhousie University, Department of Health and Human Performance, Halifax, Canada

Purpose: The benefits of spending time in or with nature are critical for supporting the physical, mental, and social wellbeing of youth. Positive Youth Development (PYD), a prosocial approach to adolescence, promotes wellbeing by creating opportunities for youth to develop and acknowledge their strengths to support themselves and thrive

N. MENTAL HEALTH AND WELLBEING

in society. While some studies have explored the role of nature for PYD, little evidence exists for Canadian youth, employing mixed methods approaches, or drawing connections to Lerner's six key competencies (Cs) of PYD (confidence, competence, connection, character, caring, and contribution). The aim of this study is to explore how youth living in Nova Scotia (NS; a province in Atlantic Canada) perceive the benefits of nature exposure in relation to PYD competencies using a mixed-methods online survey.

Methods: The NS Youth, Nature, and Wellbeing Survey was created for youth aged 13-18 years, informed through literature reviews and youth focus groups. Participants are asked to indicate their agreement with the benefits of nature as related to each PYD competency through 14 Likert-scale questions. Youth are also asked one open-ended question to provide context on what they feel are the most important benefits of spending time in nature.

Results: As of November 2025, ~100 youth have completed the survey. This survey aims to recruit 300 participants in alignment with past NS youth health surveys. Descriptive statistics will be calculated to understand central tendencies and distributions. Deductive content analysis will be used for the open-ended question using the 6Cs of PYD as codes to identify patterns and themes. Findings will be integrated using a concurrent mixed-methods approach.

Conclusion: Our survey is the first in Canada to explore youth's perceptions of the contribution of nature exposure to the 6Cs of PYD. Findings will be shared with partners and professionals across disciplines (e.g., healthcare, recreation, educators, policymakers), youth, and the broader community, and used to inform recommendations to increase NS youth access to nature as a mechanism for supporting PYD and overall wellbeing.

I-P-N.06

Healing Outdoors: Green Spaces in Young Adult Mental Health Recovery

M. Moran¹, A. Ginzburg¹

¹University of Haifa, School of Public Health, Haifa, Israel

Purpose: While abundant literature links greenspace with mental health, most studies focus on the general population, and less is known about individuals with mental illness. This study examines young adults (18–30 years) with mental illnesses to assess how greenspace access and use relate to mental health outcomes and to explore participants' experiences. We hypothesize that greater greenspaces access and use improves mental health.

Methods: This cross-sectional mixed-methods study included a self-administered survey among young adults in five rehabilitation hostels different cities in Israel. The questionnaire outcomes included anxiety (GAD-7), stress (PSS-10), and depression (PHQ-9). Greenspace exposure included natural window-view and sound, distance to the nearest park, and park visits' frequency and duration. Socio-demographic and clinical variables were controlled for. Following the survey, focus groups and participatory mapping explored participants' perceptions and preferences regarding greenspaces. Transcripts were analyzed in a mixed qualitative-spatial approach to identify locations and themes.

Results: 64 participants completed the survey (mean age 22.6; 45% women; 84% Jewish; 48% employed), of which, 17 engaged in the participatory mapping (2-6 per hostel). After adjustments, greenspace access and use were mainly associated with depression, less with stress, and not with anxiety. Associations were inconsistent. Increased depression was linked with window sounds, like birdsong ($\beta=0.07$, $p=0.002$) and rustling leaves ($\beta=0.05$, $p=0.002$). Proximity to greenspaces was associated with lower depression ($\beta=-0.22$, $p=0.001$) and stress ($\beta=-0.33$, $p=0.032$). Increased park visit frequency was linked to lower depression ($\beta=-0.06$, $p=0.008$), whereas longer visit duration was associated with higher stress ($\beta=0.11$, $p=0.033$). The participatory mapping yielded three categories: greenspace barriers, greenspace benefits, and the role of greenspace in mental health rehabilitation. The latter revealed restorative effects of greenspaces that are unique to people with mental illness, such as: reducing rumination, improving sleep, and fostering grounding.

Conclusion: This study is novel in its focus on young adults with severe mental illness, a population rarely examined in relation to greenspace exposure. While the quantitative survey results were inconclusive—likely due to the small sample size—the qualitative findings provide unique insight into the restorative potential of greenspaces in mental health rehabilitation and underscore the need for further research with larger samples.

Longitudinal Trends and Correlates of Mental Health in University Students Transitioning from University to Working Life

X.H. Chua¹, S.M. Edney¹, R.M van Dam^{1,2}, F. Müller-Riemenschneider^{1,3}, S.Y.X. Tan¹

¹National University of Singapore, Saw Swee Hock School of Public Health, Singapore, Singapore, ²The George Washington University, Departments of Exercise and Nutrition Sciences and Epidemiology, Milken Institute of Public Health, Washington DC, United States, ³Charité-Universitätsmedizin Berlin, Digital Health Center, Berlin Institute of Health, Berlin, Germany

Purpose: University students experience life-stage transitions, academic and social stressors, thereby increasing their risk towards mental health conditions. We fill critical knowledge gaps in regard to university students' mental health during the transition to work life and other sociodemographic, lifestyle, and COVID-19 correlates among university students in the post COVID-19 era.

Methods: Participants of the prospective Health@NUS cohort study completed a questionnaire at baseline, 12, and 24 months comprising sociodemographic, lifestyle, and COVID-19 infection-related information, and self-reported their mental well-being (WHO-5 Well-Being Index [WHO-5]) and psychological distress (Kessler 6 [K6]). We calculated mean scores for WHO-5 and K6, and examined their correlates using multivariable linear regression with generalised estimating equations.

Results: Participants enrolled between 2020 to 2022 with complete data were included (n=659, 57.2% females), of which 77.7% were ever infected with COVID-19. Mental well-being and psychological distress scores improved over the two-year follow up. Males (b = -2.59 [0.45, 4.72]), those living alone or with friends (b = 3.37 [0.26, 6.48]), and engaged in more physical activity (b = 3.94 per hour [2.44, 5.44]) had better mental well-being while those who consumed sweetened drinks (b = -1.72 per daily serving [-3.18, -0.27]), had not fully recovered (b = -7.33 [-11.75, -2.91]), and experienced moderate infection symptoms (b = -4.07 [-7.11, -1.03]) had poorer mental well-being. Males (b = -0.79 [-1.33, -0.25]), those of higher household income (b = -0.88 [-1.60, -0.15]), had more sleep (b = -0.37 per hour [-0.61, -0.14]), and had mild infection symptoms (b = -0.77 [-1.44, -0.10]) had lower psychological distress, while those who consumed sweetened drinks (b = 0.69 per daily serving [0.28, 1.09]) had higher psychological distress. Transition to work life, number of COVID-19 infections, and time since the last COVID-19 infection were not associated with either mental well-being or psychological distress.

Conclusion: This study offers a novel perspective on the longitudinal trends in mental health among university students post COVID-19. We highlight specific subgroups vulnerable to poor mental health among university students in Singapore that require holistic interventions focusing on lifestyle behaviours, with evidence suggesting that interventions may not need to differentiate by life-stage transition.

I-P-N.10

Pre- and Postnatal Maternal Psychological Distress and the Metabolomic Profile of Human Milk

N. Ryan¹, A.-K.A. Aatsinki², S. O'Mahoney³, P. Leahy-Warren¹, H. Mulcahy¹, L.F. Philpott¹, U.K. Sundekilde⁴, A.M. Dickens⁵, H.-M. Kalant⁶, S. Lamichhane⁷, H. Isokääntä⁸, L. Perasto⁶, S. Tarro⁸, H. Karlsson⁹, L. Karlsson⁶

¹University College Cork, School of Nursing and Midwifery, Cork, Ireland, ²University of Turku, Medicine, Turku, Finland, ³University College Cork, Department of Neuroscience, Waterford, Ireland, ⁴Aarhus University, Department of Food Science, Aarhus, Denmark, ⁵University of Turku, Chemistry, Turku, Finland, ⁶University of Turku, Clinical Medicine, Turku, Finland, ⁷University of Turku, Bioscience Centre, Turku, Finland, ⁸University of Turku, Population Health Research, Turku, Finland, ⁹University of Turku, Psychiatry, Turku, Finland

Purpose: Human milk is the gold standard of infant nutrition, providing nutrients and bioactive metabolites that shape infant immune, cognitive, and metabolic development. Maternal psychological distress, including stress, anxiety, and depression, is prevalent during the perinatal period and may influence milk composition. Evidence suggests these conditions can alter metabolite classes, with potential long-term consequences for health.

Objective: To identify whether maternal stress, depressive, and anxiety symptoms are associated with differential metabolomic signatures in human milk from 2.5 to 24 months postpartum.

Our study is the first to advance this field of research by incorporating repeated measures of maternal stress, depression, and anxiety, with multiple milk samples collected from 2.5 to 24 months, enabling examination of how

N. MENTAL HEALTH AND WELLBEING

links between maternal psychological states and milk metabolomic profiles evolve across lactation.

Methods: This data is derived from the FinnBrain Birth Cohort Study, a prospective observational study. Human milk samples were collected from 2.5 to 24 months postpartum. Maternal depressive, anxiety, and stress symptoms were assessed using validated self-report scales pre- and postnatally. Simple linear regression and linear mixed models examined associations between maternal symptom scores and human milk metabolite concentrations across lactation.

Results: Associations between maternal psychological distress and milk metabolites were heterogeneous, with both positive and negative relationships across classes and timepoints. Several human milk oligosaccharides (LNT, LNFP I, LNDFH I/II) showed negative associations with depressive and stress symptoms, while others (3'FL, 3'SL, LNT) were positively linked, particularly with prenatal symptoms. Amino acids such as threonine were reduced, whereas glutamate, glutamine, and taurine showed dynamic, time dependent associations. Energy metabolites such as succinate and hippurate were generally positively associated with prenatal symptoms but negative at later timepoints, while lactose and caprylate were mainly negatively associated with postnatal symptoms.

Conclusion: Both prenatal and postnatal maternal distress is associated with human milk metabolites. Human milk may buffer infants from some effects of maternal psychological distress, as increases in key metabolites suggest potential compensatory roles in immune modulation and healthy gut microbiota. However, reductions in metabolites with established prebiotic and immune regulatory functions reinforce the importance of interventions that support maternal mental health during the perinatal period.

I-P-N.11

Body Functionality Appreciation Buffers the Association between Negative Body Image and Problematic Eating Behaviors during Pregnancy

M.-F. Beaudin^{1,2}, M. Plouffe^{1,2}, A.-F. Tessier^{1,2}, M.-P. Gagnon-Girouard^{1,2}, A.-S. Morisset^{3,2,4}, É. Carbonneau^{3,2,4}, F.-A. Guimond⁵, C. Maïano⁶, G. Lavigne¹, N. Carbonneau^{1,2}

¹Université du Québec à Trois-Rivières, Psychology, Trois-Rivières, Canada, ²Institute of Nutrition and Functional Foods (INAF), Québec, Canada, ³Université Laval, School of Nutrition, Québec, Canada, ⁴Centre Nutrition, Santé et Société (NUTRISS), Québec, Canada, ⁵University of Ottawa, Psychology, Ottawa, Canada, ⁶Université du Québec en Outaouais, Psychology, Gatineau, Canada

Purpose: Pregnancy can lead to significant changes in women's relationships with their bodies and eating behaviors. Previous research has shown that body functionality appreciation (i.e., respecting and valuing one's body for what it can do) is associated with a more compassionate approach to one's appearance and a more positive relationship with food. The present study aimed to extend this work by examining whether body functionality appreciation during pregnancy moderates the association between negative body image and problematic eating behaviors.

Methods: The study included 245 pregnant women (M = 31.26 years, SD = 3.66) from Canada in their third trimester. The online questionnaire assessed body functionality appreciation (Functionality Appreciation Scale), seven dimensions of body image (Body Image in Pregnancy Scale), and three types of problematic eating behaviors (Dutch Eating Behaviour Questionnaire): restrained eating (i.e., deliberate control of food intake to influence body weight and shape), emotional eating (i.e., eating in response to negative emotions), and external eating (i.e., eating in response to external food cues). Correlational and linear regression analyses were performed to examine associations and test moderation effects.

Results: Most positive body image dimensions were negatively correlated with problematic eating behaviors, whereas most negative dimensions were positively correlated with them. For example, greater preoccupation with appearance was associated with more restrained ($r = .64, p < .001$), emotional ($r = .35, p < .001$), and external ($r = .24, p < .001$) eating. Regression analyses further revealed that body functionality appreciation moderated the associations between several negative body image dimensions and eating behaviors. For instance, body functionality appreciation buffered the positive association between concerns about sexual attractiveness and emotional eating. Similarly, the positive associations between appearance prioritization and all three eating behaviors were weaker among women reporting higher levels of functionality appreciation.

Conclusion: Overall, this study highlights the protective role of body functionality appreciation during pregnancy. Among pregnant women who valued their body functionality, body image concerns were less strongly related to nonoptimal eating behaviors. These findings suggest that fostering body functionality appreciation may help promote a healthier relationship with food among pregnant women experiencing body image concerns.

Muscularity, Thinness and Body Image in Gay Men: Links to Subcommunity Identity

M. Mireault¹, J. Flores-Aranda², M.-P. Gagnon-Girouard¹

¹Université du Québec à Trois-Rivières, Psychology, Trois-Rivières, Canada, ²Université du Québec à Montréal, Social Work, Montréal, Canada

Purpose: Given the central importance of appearance and beauty ideals within the gay male community, internalization of the importance of being muscular and/or thin are likely to be particularly salient. More specifically, a large proportion of gay men identify with a specific subcommunity (SC), such as *bears*, *jocks*, or *twinks*. These SC share distinct embodied physical traits and gendered norms, that might lead to specific physical activity and eating behaviors. This study is the first to study SC in terms of body image. The aim of the study is to compare SC (*bear*, *jock*, *twink*, *no SC*) in terms of muscularity/thinness internalization and body esteem.

Methods: Participants were 527 cisgender gay men ($M = 37.41$ years old; $SD = 12.71$) recruited online across Canada. They completed a questionnaire measuring sociodemographic characteristics, internalization of muscularity and thinness (SATAQ-4) and body image (Body Esteem Scale). To examine differences across SC identifications, a multivariate analysis of variance was conducted.

Results: *Jocks*-identified participants showed greater internalization of muscularity than other SC identifications ($F(3) = 24.69, p < 0.001$), with large effect sizes. *Twink*-identified participants showed greater internalization of thinness than *bear* and *no SC* participants ($F(3) = 4.75, p = 0.003$), with small to moderate effect sizes. Appearance-related body esteem did not differ across SC ($F(3) = 1.24, p = 0.296$). *Bears*-identified participants reported lower weight-related body esteem than other SC identifications with small to large effect sizes while *jocks*-identified participants reported higher body esteem related to weight than participants with *no SC identification*, with large effect size ($F(3) = 14.09, p < 0.001$).

Conclusion: Findings might reflect the endorsement of specific physical characteristics associated with the SC with which gay men identify. These ideals may, in turn influence behavioral patterns such as physical activity aimed at aligning with the SC physical characteristics. This study contributed to the understanding of how sociocultural contexts affect body image processes within sexual minority identities, highlighting the need for inclusive and tailored interventions in behavioral nutrition and physical activity promotion.

I-P-N.14

Improving Treatment through a Better Understanding of Profiles of Sexual Dispositions among Women with Binge Eating

G. Martin¹, M.-P. Gagnon-Girouard²

¹Université Laval, Psychiatry and Neurosciences, Quebec, Canada, ²Université du Québec à Trois-Rivières, Psychology, Trois-Rivières, Canada

Purpose: Although it plays a key role in physical and mental health and well-being, sexuality has received little empirical attention in relation to eating disorders, aside from dysfunctions. To date, little is known about the perceptions individuals with eating disorders hold about sexuality, as well as their sexual fantasies, practices and experiences. However, a greater understanding of the positive sexual dispositions that can act as protective factors in treatment and increase well-being could transfer into a stronger sense of empowerment and positive embodied and relational experiences among individuals with an eating disorder. The objective of the study was to verify the presence of distinct profiles of sexual dispositions among women with binge eating episodes.

Methods: Participants were 253 adult females with recurrent and sustained episodes of binge eating in the past five years. They completed an online questionnaire including the following measures: a sociodemographic and sexorelational questionnaire, the Multidimensional Sexual Self-Concept Questionnaire (Snell, 2002), the Derogatis Sexual Functioning Inventory (Derogatis, 1978), the Arizona Sexual Experience Scale (McGahuey et al., 2000), the Sexual Pleasure Scale (Pascoal et al., 2016), and the Sexual Motivation Scale (Gravel et al., 2016). A two-step cluster analysis was performed to detect possible homogenous groupings based on similar dispositions toward sexuality. T-tests were used to specify the characteristics of each profile.

Results: Two profiles were identified, including each 50% of the sample. The first profile was associated with a more positive sexual self-concept, better sexual functioning and a wider range of sexual practices. The second profile

N. MENTAL HEALTH AND WELLBEING

was characterized by poor investment of sexuality, marked by later age at first sexual interest and consensual sexual relationship, more fear and avoidance of sexuality, fewer sexual fantasies, the experience of more sexual difficulties and less sexual pleasure, and fewer autoerotic and partnered sexual practices. Profiles did not differ relative to binge eating.

Conclusion: Concrete recommendations will be provided for the adaptation of treatment according to the presence of specific sexual dispositions among women with binge eating episodes. This will help fill the current lack of a strong empirical base, which can orient interventions that target both sexual health and well-being and sexual difficulties.

I-P-N.16

Understanding the Characteristics of a Trauma Informed Practice Training Program for Exercise Professionals

G. Ike¹, J. Cairney¹, E. Berger², K. Wheeler¹

¹The University of Queensland, School of Human Movement and Nutrition Sciences, Brisbane, Australia, ²Monash University, Melbourne, Australia

Purpose: Trauma is a major public health concern. Approximately 70% of people experience a traumatic event in their lifetime, which can lead to lasting adverse health effects. Trauma Informed Practice (TIP) is a strength-based approach to healthcare delivery that seeks to minimise re-traumatisation, by recognising and responding to the impacts of trauma. There is growing support for the adoption of TIP in Exercise Professions given the role they play in managing health outcomes, however there is a lack of tailored training programs to support its implementation. This study aimed to understand the needs and perspectives of Exercise Professionals on the design characteristics of a TIP training program and to generate ideas to inform its development.

Methods: A qualitative exploratory design was employed, by conducting semi structured interviews with 14 Exercise Professionals, including Exercise Physiologists, Physiotherapists, Occupational Therapists, and Yoga instructors. The participants interviewed in this study were experienced Exercise Professionals who had undertaken additional training and research on TIP and were currently applying these principles in their professional practice. Interviews explored the current application of TIP across the industry, the availability of tailored training and the key design characteristics of a training program such as content, delivery methods and evaluation methods. The interviews were analysed using Braun and Clarkes thematic analysis, which identified four themes.

Results: First, a TIP training program should include content on trauma and the impacts on the body, capacity building strategies, psychological flexibility, cultural responsiveness and reporting practices. Second, participants perceive experiential and collaborative learning opportunities as essential to support practical application. Third, the program's design, delivery and evaluation should align with TIP principles such as safety, choice and empowerment. Fourth, ongoing support strategies such as mentorship and regular upskilling should be considered to support the sustainability of this approach.

Conclusion: Collectively, these findings provide a foundation for co-creating a TIP training program that equips Exercise Professionals to implement this approach.

I-P-N.17

The Effect of Exercise on Depression and Anxiety Symptoms: A Meta-meta-analysis

N. Munro¹, J. Dimmock¹, K. Somoray¹, S. Teague¹

¹James Cook University, Psychology, Townsville, Australia

Purpose: To synthesise meta-analytic outcomes from randomised controlled trials examining exercise effects on depression and anxiety across all population groups, including children and adults with both clinically diagnosed and subclinical symptoms, excluding those with pre-existing chronic physiological conditions.

Methods: Meta-meta-analysis using the PRIOR framework

Five electronic databases were searched for eligible meta-analyses published from inception to 30 September 2024. Meta-analyses of randomised controlled trials examining exercise interventions for the management of depression and anxiety symptoms were included. To avoid contamination, meta-analyses that exclusively focused on populations with chronic physiological conditions were excluded. Study selection was undertaken in duplicate by two independent reviewers.

N. MENTAL HEALTH AND WELLBEING

Results: Sixty-three studies (81 meta-analyses, 1,079 component studies, 79,551 participants) were included. Exercise reduced depression (SMD = -0.61, 95% CI -0.69 to -0.54) and anxiety symptoms (SMD = -0.47, 95% CI -0.59 to -0.36), with aerobic exercise demonstrating the most substantial impact on both depression and anxiety symptoms. The greatest benefits by population group for depression were seen in emerging adults aged 18 to 30 and post-natal females. Greater reductions in depression were associated with exercise in group and supervised settings. Exercise of shorter duration and at lower intensity was most strongly associated with anxiety reduction.

Conclusion: Findings support that exercise-based interventions, in all formats and parameters, can help mitigate depression and anxiety symptoms across all population categories. These results can help health professionals provide targeted, cost-effective, evidence-based support that aligns with individual profiles and preferences. This meta-meta-analysis is the first to comprehensively isolate the effect of exercise on both depression and anxiety across clinically diagnosed and non-clinical populations, including children, emerging adults, older adults, and perinatal females.

Exercise is effective across all population groups, with aerobic, group-based, and supervised formats showing the greatest benefits for depression. Differences in the impact of exercise intensity, duration and frequency are revealed between depression and anxiety-based populations. The effectiveness of exercise interventions appears comparable to pharmacological treatments and psychotherapies for managing depression and anxiety symptoms.

I-P-N.18

LIVE WELL – Mapping Behaviour Change Techniques to Inform a Community-based Exercise Program for Women with Depression

V. Whiteford¹, P. Holliday², A. Shwed², H. Gainforth², M. Gierc¹, G. Faulkner¹

¹University of British Columbia, Kinesiology, Vancouver, Canada, ²University of British Columbia, Health and Exercise Sciences, Kelowna, Canada

Purpose: Existing community-based exercise programs may be an appropriate setting within which to deliver exercise-based interventions for women with depression. Retrospectively applying a theoretical framework to “reverse code” an existing community-based exercise program can support the identification of elements of the program that may be missing or need refining. The aim of this study was to use the Behaviour Change Intervention Ontology (BCIO) to reverse code a community-based exercise program with a focus on setting, delivery, and content (e.g., behaviour change techniques).

Methods: We applied a mixed method research design across two stages. Stage 1: the BCIO was applied to determine what BCTs does the community-based exercise program already deliver, what if anything is missing from the program, and what behavioural support does the program need to be supplemented with to meet the needs of women with depression. Stage 2 was the development of a behaviour change counselling manual informed by the Behaviour Change Taxonomy v1 (BCTTv1). The manual was then coded using the Behaviour Change Technique Ontology (BCTO) to identify BCTs present in the manual.

Results: Stage 1: We found that the community-based exercise program provides a comprehensive program encompassing 39 BCTs, including many of the common BCTs delivered in physical activity behaviour change interventions (e.g., goal setting, action planning). However, there was a lack of focus on BCTs linked to the emotion domain of the theoretical domains theory (TDF). The need to explicitly incorporate these BCTs within the exercise program to address the complexity of depression and to align with the needs of women with depression was identified. Stage 2: the behaviour change counselling manual encompassed 32 BCTs, including emotion based BCTs (e.g., inform about positive emotional consequences, monitor emotional consequences).

Conclusion: This study demonstrates how systematic reverse coding using the BCIO can characterise the content of an existing community-based exercise program, identify missing but relevant BCTs, and inform the development of enhanced intervention components. This approach provides a template for researchers seeking to evaluate and strengthen existing behaviour change interventions to maximise effectiveness.

N. MENTAL HEALTH AND WELLBEING

I-P-N.19

Correlated Changes in Health Behavior and Mental Health

K. Konstabel¹

¹National Institute for Health Development, Tallinn, Estonia

Purpose: To investigate correlated changes in mental health (MH) and health behavior (HB). It is hypothesized that positive changes in health behaviour (e.g. increasing physical activity) will be related to positive changes in well-being (e.g., increase in life satisfaction or decreases in depressiveness).

Methods: The data are from Estonian National Mental Health Study, a population based study (Laidra et al., 2023) in 3 waves of data collection (2021-2022). The analyses are based on 3277 participants who provided responses in at least 2 waves. The analysis of change scores is based on latent change score modelling.

Results: Changes in depression are negatively correlated with changes in sleep duration (-0.29;-0.38), physical activity (-0.21; 0.46) and positively with disordered eating (0.35; 0.27). Changes in well-being are weakly but significantly correlated with changes in sleep duration (0.05; 0.05) and physical activity (0.07-0.05) but mostly unrelated to changes in disordered eating. The two numbers in parentheses refer to standardized covariance parameters from latent change score model - corresponding respectively to changes from January to May 2021, and from May 2021 to January 2022. For all variables, there was negative autoregression of change scores: i.e., any change in the first time period was likely to be followed by the opposite change in the second time period.

Conclusion: Changes in mental health and three domains of health behaviour (sleep, PA, disordered eating) are significantly correlated. Most importantly, changes in depression symptoms are correlated with changes in sleep duration and disordered eating. The negative autoregression coefficients can be explained by a „bounce-back“ effect (falling back to the initial level after a temporary change).

I-P-N.20

Effectiveness of the Health4Me Text Message Intervention to Improve Adolescent Mental Health Outcomes: Secondary Analysis of a Randomised Controlled Trial

R. Raeside¹, A.R Todd¹, S.R Partridge¹, T. Health4Me Team¹

¹The University of Sydney, Sydney, Australia

Purpose: The shared protective factors for mental health and non-communicable diseases, including good nutrition and regular physical activity, deserve greater attention. Evidence shows that digital health interventions targeting these behaviours have potential to improve adolescents' mental health. However, high-quality evidence is limited. This secondary analysis of a randomised controlled trial assessed whether the Health4Me text message intervention improved adolescent mental health outcomes over six months compared with usual care.

Methods: Virtual randomised controlled trial (RCT, 1:1, intervention: control) among adolescents (n=390; 12-18-years; living in Australia). Intervention received 6-month co-designed, semi-personalized behaviour change text message intervention (4-5 texts/week). Primary outcomes: change in moderate to vigorous physical activity (MVPA) min/day (collected via GeneActiv accelerometers) OR change in proportion of participants meeting vegetable intake guidelines (>3 serves/day, collected via Australian Child and Adolescent Eating Survey). Secondary outcomes: mental health (collected via self-report validated surveys) including health-related quality of life (CHU-9D), anxiety symptoms (GAD-7), depressive symptoms (CESD-10) and psychological distress (K6). At 6 months, continuous outcomes were compared between groups using unadjusted tests (independent t-tests or ANOVA for normally distributed data, and Wilcoxon rank-sum tests for skewed data). The primary analysis used ANCOVA, adjusting each 6-month outcome for its baseline value. Analyses followed the intention-to-treat principle. Trial registration: ANZCTR N12622000949785.

Results: Baseline demographic data was available for 365/390 participants (mean age±SD=16±1). 70% (250/357) were female, 17% (62/357) spoke a language other than English. 73% (251/346) lived in major cities. 85% (309/365) completed 6-month follow-up. At 6-months, there was a positive impact on vegetable intake and maintenance of physical activity, but neither primary outcomes were statistically significant. A significant decrease in depressive symptoms was observed at 6-month follow-up (mean difference -1.56 [95% CI -2.96, -0.16], p<0.05). There were no significant differences in health-related quality of life, anxiety symptoms, or psychological distress.

Conclusion: Although Health4Me did not significantly improve the primary behavioural outcomes (nutrition/physical activity), it reduced depressive symptoms, suggesting value for supporting adolescent mental wellbeing. Future studies should explore refining the intervention with a stronger focus on mental health outcomes.

Appetitive Trait Profiles and Body Image among Adults: A Latent Profile Analysis

L. Vermette^{1,2}, T. Sire^{1,2}, C. Lavoie^{3,1,2}, M.-F. Beaudin^{1,2}, G. Lavigne^{1,2}, N. Carboneau^{1,2}

¹University of Quebec in Trois-Rivieres (UQTR), Trois-Rivieres, Canada, ²Institute of Nutrition and Functional Foods (INAF), Quebec, Canada, ³University of Quebec in Montreal (UQAM), Montreal, Canada

Purpose: Appetitive traits are predispositions toward foods that interact with environmental factors to influence eating behaviors, dietary patterns, and weight trajectories. Research using latent profile analysis (LPA) to examine various appetitive traits – including food approach traits (i.e., hunger, food responsiveness, emotional overeating, enjoyment of food) and food avoidance traits (i.e., satiety responsiveness, emotional undereating, food fussiness, slowness in eating) –among adults remains scarce. Furthermore, little research has examined how appetitive traits relate to body image.

This research aimed to investigate whether and how adults' appetitive traits relate to key dimensions of body image, including body esteem (defined as the positive appreciation and evaluation of one's body) and body dissatisfaction (defined as the perceived discrepancy between one's current and ideal body).

Methods: A cross-sectional sample of 441 French-Canadian adults ($M = 38.7$ years; $SD = 6.2$; 74.8% women; 95% White) completed questionnaires assessing appetitive traits, body esteem, and body dissatisfaction. LPA was conducted to identify homogeneous subgroups of participants based on their appetitive trait scores. Differences in body esteem and body dissatisfaction across profiles were examined using analysis of covariance (ANCOVA), controlling for age and BMI.

Results: A three-profile solution was retained based on statistical indicators and existing literature: (1) *Typical eating* (47.8%), characterized by near-average levels across both approach and avoidance traits; (2) *Low-approach eating* (34.1%), marked by similar levels of food avoidance traits as those observed in the Typical profile and the lowest levels of food approach traits across profiles; and (3) *Avid eating* (18.1%), defined by the highest food approach traits and the lowest levels of two food avoidance traits (i.e., satiety responsiveness and emotional undereating) across profiles. Participants in the *Avid eating* profile reported lower body esteem and higher body dissatisfaction compared with those in either the *Typical* or *Low-approach eating* profiles, which did not significantly differ from each other.

Conclusion: These findings highlight meaningful heterogeneity in adults' appetitive traits, suggest that individuals with higher food approach tendencies could be more vulnerable to negative body image, and provide directions for future research and interventions in nutrition and eating psychology.

I-P-N.22

Patient Preferences for the Integration of Exercise for Depression into Mental Health Care

T. Dregney¹, S. Kaja², H.-M. Eadeh³, M. Adkins-Hempel⁴, L. Uebelacker⁵, L. Sylvia⁶, A. Abrantes^{5,7}, A. Busch⁴

¹University of Minnesota, Department of Family Medicine, Minneapolis, United States, ²University of Minnesota, Department of Pediatrics, Saint Paul, United States, ³Hennepin Healthcare Research Institute, Department of Psychiatry, Minneapolis, United States, ⁴Hennepin Healthcare Research Institute, Department of Behavioral Medicine and Pharmacology, Minneapolis, United States, ⁵Brown University, Department of Psychiatry and Human Behavior, Providence, United States, ⁶Massachusetts General Hospital, Dauten Family Center for Bipolar Treatment Innovation, Boston, United States, ⁷Butler Hospital, Behavioral Medicine and Addictions Research Group, Providence, United States

Purpose: Exercise is an evidence-based treatment for depression, yet it is rarely integrated into mental health care. Many U.S. mental health providers acknowledge the value of exercise for depression, and U.S. patients are interested in exercise for depression. However, patient perspectives on its incorporation into mental health care are not well understood.

Methods: Participants were 457 U.S. adults with depression who reported current or past receipt of mental health care and completed an online survey assessing their past experiences with exercise integration within mental health care and preferred level of exercise integration, each measured using parallel three-level ordinal scales. Related samples Wilcoxon signed-rank tests compared experienced versus preferred levels of exercise integration. Multivariable ordinal logistic regression examined predictors of preferred exercise integration.

N. MENTAL HEALTH AND WELLBEING

Results: 22.5% preferred no discussion of exercise in mental health care, 56.5% preferring general education and encouragement around exercise in mental health care, and 21.0% preferring structured exercise goal setting in mental health care. Participants preferred significantly greater exercise integration than they had experienced ($Z = 6.8, p < .001$). In multivariable analyses, prior experience with exercise being integrated into mental health care and greater belief in exercise's antidepressant effects were associated with higher preferred integration, whereas current antidepressant use and physical health conditions limiting exercise were associated with lower preferred integration. Preference for integration of exercise into mental health care was unrelated to depression severity or physical activity level.

Conclusion: U.S. adults with depression prefer greater integration of exercise into mental health care than they currently receive, but most prefer limited integration. These findings highlight the importance of flexible, patient-centered approaches to exercise integration into mental health care.

II-P-N.01

Association between Physical Activity and Perceived Health among Women of Reproductive Age in the United States: Insight from the National Health and Nutrition Examination Survey 2021–2023

R. Sarbah¹, T. Ramos Flores¹, R. Miranda Tassitano¹, G. Kpene¹, T.N. Folorunso¹, C. Marinho Tenorio¹

¹University of Illinois Urbana-Champaign, Health and Kinesiology, Urbana-Champaign, United States

Purpose: Physical activity (PA) plays a crucial role in promoting physical and psychological well-being. Despite its importance, U.S. national evidence on how PA influences self-rated health, a key indicator of perceived health (PH) status and future morbidity risk among women of reproductive age, remains limited. This study examined the association between PA and perceived health using data from NHANES 2021–2023.

Methods: Data were drawn from the 2021–2023 NHANES, dataset a nationally representative cross-sectional survey of the U.S. population. The analytic sample included women aged 20–44 years ($n \approx 1,500$). PA was defined as participation in any moderate/vigorous activity during a typical week, while perceived health was categorized as good/very good/excellent versus fair/poor. Covariates included pregnancy status, age, race/ethnicity, education, income, smoking, and sedentary time. All analyses accounted for NHANES' complex survey design and were conducted using weighted descriptive statistics and survey-weighted logistic regression to examine the association between PA and PH.

Results: Weighted analyses indicated that 86.8% (95% CI: 84.3–89.3%) of women engaged in some form of PA, and 87.2% (95% CI: 85.0–89.4%) reported good/very good/excellent PH. A higher proportion of physically active women reported good perceived health compared to inactive women (90.1% vs. 68.7%, $p < .01$). In survey-weighted logistic regression models, PA was associated with higher odds of perceived good health (AOR = 2.50, 95% CI: 1.29–4.83, $p = .016$). Higher educational attainment was also positively associated with perceived health (AOR = 2.68, 95% CI: 1.24–5.79, $p = .022$), whereas age was inversely related (AOR = 0.97, 95% CI: 0.95–0.996, $p = .032$). Pregnancy status and smoking were not significantly associated with Perceived Health. The overall model explained approximately 18% of the variance in PH (pseudo- $R^2 = 0.18$), indicating a moderate model fit typical of population-based behavioral studies.

Conclusion: Women who reported any level of PA were more than twice as likely to perceive their health positively compared to inactive women. These findings highlight the importance of promoting even modest PA to enhance perceived well-being and reduce health disparities among women of reproductive age.

II-P-N.02

Testing a Group-based Physical Activity Intervention on Psychosocial Outcomes in Queer Women: A Proof-of-concept Study

M. Sutton¹, J. Bailey², S. Němeček¹, E. Pila¹

¹Western University, School of Kinesiology, London, Canada, ²McGill University, Montreal, Canada

Purpose: Queer women engage in the lowest levels of physical activity (PA) behaviours compared to all other non-heterosexual communities, translating to disproportionately adverse health outcomes. These low levels of PA are likely owing to a particular set of barriers (e.g., homophobia, sexism, overt discrimination) which uniquely intersect and limit the engagement and enjoyment of PA for queer women and prevent such individuals from reaping the plethora of health benefits associated with regular PA engagement. Despite calls to address these inequities, there

N. MENTAL HEALTH AND WELLBEING

have been no documented interventions designed to dismantle the specific barriers experienced by queer women in PA. As such, the present study aimed to i.) examine the feasibility and acceptability of a group PA intervention for queer women, and to ii.) establish preliminary evidence of the effectiveness of this intervention in improving basic psychological needs, perceived social support, hypervigilance, and body appreciation in this population.

Methods: Self-identified queer women ($N = 11$; $M_{\text{age}} = 24.73$) engaged a 6-week co-designed queer-led physical activity intervention. Psychological assessments were administered at baseline, post-intervention and at 3-month follow-up and explored using paired t-tests. Adherence, attrition, acceptability, and program enjoyment was assessed post-intervention, alongside focus groups for in-depth exploration of experiences using reflexive thematic analysis.

Results: Engagement in an intentionally queer-inclusive physical activity program held in a private space supported queer women's experiences, enjoyment, and retention of physical activity behaviours. Participants reported improved psychological outcomes ($t_{\text{PNSE}} = -1.40, p = 0.13$; $t_{\text{SSQ-6}} = -2.30, p < 0.05$; $t_{\text{HV}} = 3.78, p < 0.05$; $t_{\text{BAS}} = -2.75, p < 0.05$) and the program was acceptable ($M_{\text{TAQ}} = 36.5$) and feasible to implement ($M_{\text{adherence}} = 86.5\%$; Attrition = 18%).

Conclusion: This proof-of-concept study is the first PA intervention that aimed to provide queer women with an opportunity to engage in safe and accessible PA that is removed from traditionally heteronormative fitness environments. This study has identified novel factors, considerations, and insights (e.g., queer-identified leadership, cultural sensitivity, intentionally inclusive language, resisting heteronormativity) which can support the development and implementation of effective physical activity interventions for queer women in broader contexts.

II-P-N.03

The Effects of Intermittent Fasting on Eating Behaviors and Appetite in Adolescents and Adults with Overweight and Obesity: A Systematic Review and Meta-analysis

C. Pacanowski¹, S. Lorien², J. Goldberg³, I. Jardine², H. Jebeile², N. Lister², H. Cash⁴

¹University of Delaware, Health Behavior and Nutrition Sciences, Newark, United States, ²The University of Sydney, Children's Hospital at Westmead Clinical School, Western Sydney (Baludarri) Precinct, Australia, ³University of Connecticut, EMPOWER Lab, Department of Psychological Sciences, Storrs, United States, ⁴University of Delaware, United States

Purpose: Intermittent Fasting (IF) improves cardiometabolic health, yet the impact of different types of IF on eating behaviors and appetite is poorly understood and is an important consideration for mental health and wellbeing. This review aims to determine how different types of IF impact eating behaviors and appetite for adolescents and adults with overweight and obesity.

Methods: This systematic review and meta-analysis is being conducted in accordance with PRISMA guidelines and was preregistered with PROSPERO (CRD420251106320) and the Open Science Framework. Five databases (including clinical trial registries) were searched to July 1, 2025, with no language or date restrictions. Eligibility criteria were: randomized controlled trials (RCTs), participants aged ≥ 10 years with overweight/obesity; any IF intervention with a duration of ≥ 4 weeks (including time restricted eating (TRE), modified alternative day fasting (MADF), 2:5 diet, religious fasting, intermittent energy restriction); measured eating behaviors and cognitions (e.g., dietary restraint, food reward, emotional/external eating) or appetite (self-reported hunger/fullness and measured hormones e.g., ghrelin, CCK, leptin) before and after the intervention. Random effects meta-analysis will be used to combine outcome data, and the differential impact of IF types on outcomes will be evaluated. The primary outcome will be standardized mean difference in eating behaviors and appetite. Results will be compared by age group (adolescent/adult). Risk of bias will be assessed using the JBI critical appraisal tool for RCTs.

Results: The search retrieved 2,971 records. After deduplication, 1,487 title/abstracts were screened by two independent reviewers, leaving 740 full texts. The most frequent reason for full-text exclusion was not including eating/appetite outcomes ($n=205$). Of 54 included studies, 51 were in adults and 3 were in adolescents. TRE was the most common intervention ($k=26$), followed by MADF ($k=12$). Eating behaviors were assessed in 20 studies, subjective appetite was assessed in 25 studies, and hormones were measured in 29 studies.

Conclusion: As IF is a popular diet strategy, this review is timely and will provide a comprehensive assessment of the effect of different types of IF on eating behaviors and appetite outcomes, in addition to comparing effects in adolescents and adults.

N. MENTAL HEALTH AND WELLBEING

II-P-N.04

Beyond Food Access: The Protective Effect of Adult and Peer Connection on Mental Wellbeing in Food Insecure Adolescents

L. Boyar^{1,2}, L. Mâsse^{1,2}, E. Obele²

¹BC Children's Hospital Research Institute, Vancouver, Canada, ²University of British Columbia, School of Population and Public Health, Vancouver, Canada

Purpose: While food insecurity has been consistently linked to adverse mental health outcomes among adolescents, little is known about its relationship with positive aspects of mental wellbeing crucial for resilience, or the role of social connection. This study investigates the association between food insecurity and adolescents' mental wellbeing, including whether connectedness with adults and peers moderates this association.

Methods: Cross-sectional population-based self-report surveys were conducted during the 2024-2025 school year with 18,846 Canadian adolescents attending grades 6-8 in public schools. Surveys assessed food insecurity, negative (depressive symptoms, anxiety) and positive (optimism, satisfaction with life) indicators of mental wellbeing, adult connection, and peer belonging. Linear mixed effect models nested by school examined differences in mental wellbeing by food insecurity status (food insecure vs. secure), adjusting for grade, gender, and ethnic background. Moderation analyses tested the effect of adult connection and peer belonging in modifying these associations.

Results: Compared to food secure adolescents, food insecure adolescents reported greater anxiety (1.92 vs. 2.45 [range:1-4], β :0.53) and depression (3.05 vs. 3.61 [range:1-5], β :0.56), and lower optimism (3.47 vs. 2.95 [range:1-5], β :-0.52) and satisfaction with life (3.52 vs. 2.91 [range:1-5], β :-0.62; $p<0.001$ for all). Greater adult connection was associated with lower anxiety to a larger extent for food secure (β :-0.32) than food insecure adolescents (β :-0.24; $p=0.006$). Greater adult connection was also associated with lower depressive symptoms among food secure (β :-0.48) versus food insecure adolescents (β :-0.27; $p<0.001$). Similar patterns across the negative mental wellbeing indicators were found by peer belonging ($p<0.001$ for all). Greater peer belonging was associated with higher optimism to a larger extent for food secure (β :0.44) than food insecure adolescents (β :0.38; $p=0.004$); no difference was found by adult connection ($p=0.211$). The effect of food insecurity on satisfaction with life was not significantly moderated by adult connection ($p=0.759$) or peer belonging ($p=0.474$).

Conclusion: Food insecure adolescents reported poorer mental wellbeing than food secure adolescents, and although social connection had a protective effect, the effect was stronger among food secure adolescents. These findings suggest that comprehensive interventions for food insecure adolescents are needed which build and sustain supportive relationships as part of broader mental health initiatives.

II-P-N.05

“Cuidem-nos” Programme to Promote Healthy Lifestyles Habits for Professionals in Osonament

M. Caro-Crous^{1,2}, M. Vilamala-Orra^{1,2}, A. Guàrdia^{1,2}, S. Montalban¹, J. Martinez¹

¹Centre Mèdic Psico-Pedagògic d'Osona, Osonament, Vic, Spain, ²Universitat de Vic - Universitat Central de Catalunya, Vic, Spain

Purpose: “Cuidem-nos” is a programme that began in 2022 to promote healthy lifestyle habits in the workplace and foster the well-being of professionals from Osonament. The main objective was to increase physical activity, reduce sedentary behaviour, improve nutritional patterns, and enhance emotional management. The programme is reviewed and updated every six months based on the feedback received.

Methods: The project includes three lines of intervention—physical activity, nutrition, and emotional well-being—and is coordinated by four professionals (two sport scientists, a dietitian-nutritionist, and a psychologist). The actions are carried out through different health promotion spaces: I) ‘Open room’: spaces into the working day for practicing physical activity (yoga, Pilates and strength training); II) Pills: weekly information capsules with recommendations on the three lines of intervention; III) Annual training activities focused on the three areas of action.

Results: Since the programme began, 162 ‘Open Room’ physical activity sessions have been held, benefiting 46 professionals (66% of whole professionals). Regarding the pills, 119 capsules have been published, with 6106 views (average of 18.7 annual views per professional), focusing on promoting an active and healthy lifestyle. The satisfaction survey (43% participation; $n=30$) shows an overall rating of 8.3/10 for the programme. Some objectives to be achieved, such as the improvement in awareness of healthy habits or the promotion of a positive attitude towards the three

N. MENTAL HEALTH AND WELLBEING

lines of action, have obtained average scores between 8.2 and 8.6. In relation to annual training activities, we carried out eight, talking about healthy eating, lower back pain, physical activity contraindications and emotional wellbeing, among others, with an average attendance of 18 to 34 professionals per training activity.

Conclusion: “Cuidem-nos” programme has impacted positively on the health of professionals, encouraging them to reduce sedentary lifestyles, increase physical activity and adopt healthy eating habits. It has also helped to consolidate a culture of wellbeing and self-care in the workplace, being an effective strategy for promoting the overall health of workers.

II-P-N.06

Promoting Intuitive Eating through Social Media: Insights from a One-year Experimental Study

A. Cassista^{1,2}, A.-A. Dufour-Bouchard³, M.-P. Gagnon-Girouard^{1,4}

¹Université du Québec à Trois-Rivières, Psychology, Trois-Rivières, Canada, ²Institute of Nutrition and Functional Foods, Université Laval, Québec, Canada, ³Groupe ÉquiLibre, Montréal, Canada, ⁴Institute of Nutrition and Functional Foods, Université Laval, Quebec, Canada

Purpose: The aim of the present study was to examine the impact of one year of exposure to online positive content on specific dimensions of intuitive eating in the general population. The main hypothesis was that individuals exposed to the four online awareness campaigns over the course of one year would demonstrate a significant improvement in intuitive eating compared to the control group.

Methods: A total of 324 participants were recruited online. The sample consisted primarily of women (N = 284) with a mean age of 33 years (M = 33.5, SD = 10.9). Participants were randomly assigned to either an experimental or a control group. Participants in the experimental group were exposed to online content created by ÉquiLibre, a French-Canadian community organization. This content included four awareness campaigns designed to challenge appearance-related pressures and promote positive eating behaviors such as intuitive eating. This experimental study was conducted over one year with five measurement time points: one pre-test assessment and one assessment following each of the four awareness campaigns. Repeated-measures analyses of variance (ANOVAs) were conducted.

Results: Participants in the experimental group showed a more significant increase than the control group regarding confidence in their hunger and satiety cues after the first campaign ($F(1,72) = 7.596, p = .007$), as well as a marginally significant cumulative effect across the overall study (T0 to T5, $F(1,72) = 3.748, p = .057$). They also showed a more significant increase regarding the congruence between bodily needs and food intake ($F(1,72) = 5.340, p = .024$) after the second campaign (which specifically focused on the “No Diet Week”). No significant differences from the control group were observed for the unconditional permission to eat and the tendency to eat for physiological rather than emotional reasons.

Conclusion: To conclude, even though the differences that were observed were small, positive content on body image and intuitive eating on social media can serve as a pathway to foster a healthier relationship with food. Its wide accessibility allows it to reach a large portion of the population at low cost and in a short period of time.

II-P-N.07

Municipal Capacity Building: Exploring Systemic Capacity for Youth Wellbeing in Faaborg-Midtfyn Municipality - The Thriving Communities Lab

N. Dugaard¹, C.B. Simonsen¹, H.T. Maindal¹, K. Ryom¹

¹Aarhus University, Department of Public Health, Aarhus, Denmark

Purpose: The purpose of this study, which is part of a larger system-oriented initiative, Thriving Communities, is to explore how key stakeholders involved in local partnerships across three Intervention Areas (sleep, timely actions and leisure time activities) in Faaborg-Midtfyn Municipality, Denmark, perceive and develop their capacity to adopt a systemic approach to youth wellbeing. The Thriving Communities initiative applies a Collective Impact framework and a systems approach to foster systemic thinking and action. The study seeks to identify factors influencing stakeholders' ability to build and sustain systemic capacity within municipal structures and partnerships. The concept of capacity building is guided by the World Health Organization's definition, emphasizing knowledge, skills, structures, systems and leadership to enable effective health promotion across individual, organizational, and community levels.

N. MENTAL HEALTH AND WELLBEING

Methods: The study employs a qualitative design using focus groups with municipal stakeholders in each intervention area. Each focus group will include 6-7 participants representing diverse sectors and roles within each intervention area. Three rounds of focus groups will be conducted between 2025-2029: a baseline and two follow-ups to capture potential changes over time. This evaluation consists of two main components: (1) readiness for systemic change using the Community Readiness Model, and (2) mechanisms and outcomes informed by the project's Theory of Change and organizational capacity literature. This combination allows for an in-depth exploration of how systemic capacity is perceived, developed, and sustained within a complex municipal context. Data will be analyzed thematically, with particular attention to shifts in readiness, collaboration patterns, and systemic understanding over time. Data will be analyzed thematically, based on an operationalisation of capacity building with particular attention to organizational capacity to think and act systemically.

Results: Preliminary analyses are expected to highlight varying levels of readiness and capacity development across the Intervention Areas. Emerging findings are anticipated to reveal key facilitators and barriers to systemic capacity building. At the conference, data from the baseline assessment will be presented.

Conclusion: This study will contribute to a deeper understanding of how municipalities can strengthen systemic capacity to promote youth wellbeing and guide future strategies for sustainable health promotion and complex interventions in local government contexts.

II-P-N.08

Exploring How Disordered Eating Behaviors and Attitudes Relate to Sexual Motivations

C. Bergeron¹, M.-P. Gagnon-Girouard¹, G. Martin²

¹Université du Québec à Trois-Rivières, Psychology, Trois-Rivières, Canada, ²Université Laval, Psychiatry and neuroscience, Quebec, Canada

Purpose: Pathological eating behaviors and attitudes, as seen in eating disorders, have been associated to multiple difficulties in the sphere of sexuality, yet only one study has examined their relationship with sexual motivations. Results from that study showed that individuals exhibiting disordered eating engaged in sexual contacts for self-validation, emotional coping, intimacy and partner approval. However, no study to date has specifically explored how distinct eating disorder behaviors and attitudes (such as dietary restriction, weight concerns, shape concerns, and binge eating) relate to these motivations. Therefore, the present study aims to address this gap.

Methods: Participants were 634 female adults aged between 18 and 71 years old ($M = 37.36$; $SD = 11.21$), reporting eating disorder symptoms (e.g.: restriction of daily food intake, loss of control over eating, and/or compensatory behaviors) in the past five years. Participants were recruited through social media posts and emails from non-profit organizations/clinics offering eating disorder or body image treatment in the province of Quebec. They responded to a self-reported online questionnaire evaluating various aspects of sexuality and eating behaviors. Descriptive analyses and bivariate correlations were performed.

Results: Behaviors and attitudes related to eating disorders were associated to a variety of sexual motivations. In particular, dietary restriction ($r = .243$, $p < .001$), shape concerns ($r = .332$, $p < .001$) and weight concerns ($r = .334$, $p < .001$) were linked with engagement in sexual contacts to feel like a good sexual partner. Binge eating was the only behavior associated with the motivation to experience affection ($r = .142$, $p = .005$). Vomiting to control one's weight was associated with the motivation of feeling similar to other people ($r = .185$, $p < .001$). Specific themes emerging from the associations between the different disordered eating attitudes and behaviors and sexual motivations were observed.

Conclusion: Different behaviors and attitudes related to eating disorders seem to be associated to distinct sexual motivations. These sexual motivations tended to reflect the need to please the partner, or to feel normal when compared to others, rather than the need to experience sexual pleasure.

II-P-N.09

Early Childhood Temperament, Parental Eating Behaviours and Adolescent Eating Competence

S. Tarro¹, R. Korja¹, H. Lagström¹

¹University of Turku and Turku University Hospital, Centre for Population Health Research, Turku, Finland

N. MENTAL HEALTH AND WELLBEING

Purpose: This study investigated associations between children's temperament and parents' eating behaviours, both assessed before school age, and eating competence measured in early adolescence.

Methods: The data for this study were drawn from the ongoing Steps to Healthy Development follow-up study, which began in 2007. Information was obtained from questionnaires completed by adolescents and their parents. Children's temperament was assessed at the age of three using the Child Behavior Questionnaire (CBQ) completed by parents. The CBQ included three dimensions: surgency, negative affectivity, and self-regulation. Parental eating behaviours were measured with the Index of Diet Quality (IDQ) and the Food Neophobia Scale (FNS), both completed by parents at child 6 years of age. Eating competence was assessed at ages 11-13 with the Satter Eating Competence Inventory (ecSI 2.0; theoretical range 0-48) completed by adolescents, and categorized either as either good (≥ 32) or poor. Associations were examined using logistic regression models.

Results: Of the 1797 study participants, 453 (50% girls; 74% from families with advanced education; and 50 % from families with high income) completed ecSI 2.0. The mean eating competence score was 35.5 (SD = 7.9), and 70% of adolescents were classified as having good eating competence. Higher child self-regulation was associated with increased odds of good adolescent eating competence (OR = 1.66; 95% CI: 1.20-2.31), whereas higher negative affectivity was associated with lower odds (OR = 0.68; 95% CI: 0.51-0.90). Child surgency was not associated with eating competence. Higher parental diet quality was associated with higher odds of good adolescent eating competence (mothers: OR = 1.20; 95% CI: 1.07-1.36; fathers: OR = 1.16; 95% CI: 1.00-1.35), whereas maternal food neophobia was inversely associated with eating competence (OR = 0.96; 95% CI: 0.94-0.98). No significant associations were observed between paternal food neophobia and adolescent eating competence.

Conclusion: Our findings demonstrate that child self-regulation and parental health-promoting eating behaviours are positively associated with adolescent eating competence. Early interventions supporting child self-regulation and promoting healthy parental eating behaviours may foster positive eating outcomes later in life.

II-P-N.10

Eating Competence and Mental Health in University Students in Brasilia, Brazil

R. Dusi¹, F.L.N. de Queiroz¹, J.R. Queiroz Soares²

¹University of Brasilia (UnB), Faculty of Health Sciences, Brasilia, Brazil, ²Brasilia University Center (UniCEUB), Medical School, Brasilia, Brazil

Purpose: This study aimed to evaluate eating competence (EatC) and its association with symptoms of depression, anxiety, and stress among university students in Brasília, Brazil.

Methods: A cross-sectional study was conducted with 184 university students (21.8 ± 2.4 years; 63.0% women), mainly enrolled in Medical School (78.3%). Participants completed an online questionnaire including sociodemographic information; self-reported weight and height; self-perceived satisfaction with body weight; eating competence assessed using the Brazilian version of the Satter Eating Competence Inventory 2.0™ (ecSI2.0™BR); and psychological symptoms measured using the Depression, Anxiety and Stress Scale (EADS-21). Data were non-normally distributed (Shapiro-Wilk test), so non-parametric tests (Mann-Whitney and Spearman correlation) were used. Chi-square or Fisher's exact tests were used for categorical associations, and odds ratios (OR) with 95% confidence intervals (CI) were calculated. A p-value < 0.05 was considered statistically significant.

Results: The mean ecSI2.0™BR score was 32.5 ± 8.7 , with 51.1% of students classified as competent eaters (ecSI2.0™BR ≥ 32). The mean EADS-21 score was significantly higher among non-competent eaters, indicating greater levels of depressive, anxiety, and stress symptoms (all $p < 0.001$). The odds of being categorized as non-competent were significantly greater among students dissatisfied with their body weight (OR = 6.71, $p < 0.001$) and among those presenting symptoms of depression (OR = 7.82, $p < 0.001$), stress (OR = 5.55, $p < 0.001$), and anxiety (OR = 2.49, $p = 0.018$). Analyses used validated categorical cutoffs for EatC and psychological symptoms. Higher ecSI2.0™BR scores were negatively correlated with stress ($r = -0.51$, $p < 0.001$), depression ($r = -0.48$, $p < 0.001$), and anxiety ($r = -0.36$, $p < 0.001$). Depression, anxiety, and stress were positively intercorrelated (all $p < 0.001$), suggesting shared psychological vulnerabilities.

Conclusion: Higher EatC was inversely associated with psychological distress among university students of higher socioeconomic status. Interventions targeting EatC may offer a feasible approach to reduce stress, anxiety, and depressive symptoms. These findings support integrating behavioral nutrition frameworks into the university curriculum to bridge nutrition education and mental health care.

N. MENTAL HEALTH AND WELLBEING

II-P-N.11

Eating Competence Improvement in Adults with Metabolic Syndrome Is Related to Improvement in Mindfulness, Stress, Health-related Quality of Life, and Depressive Symptoms

B. Lohse¹, L. Bailey-Davis², K. Herb Neff², B. Nguyen³, J. Nicklas⁴, L.H Powell⁵, E. Ruder¹, N. Trabold¹

¹Rochester Institute of Technology, Wegmans School of Health and Nutrition, Rochester, United States, ²Geisinger Health System, Population Health Sciences, Danville, United States, ³University of Missouri Kansas City, Biomedical and Health Informatics, Kansas City, United States, ⁴University of Colorado Denver, Department of Medicine, Division of Internal Medicine, Denver, United States, ⁵Rush University Medical Center, Family and Preventive Medicine, Chicago, United States

Purpose: Examine change in eating competence (EatC) over 2y in persons with metabolic syndrome participating in a lifestyle intervention trial; compare with changes in self-report measures of mental health and well-being.

Methods: Participants from 5 locations (USA) participated in a 2y randomized clinical trial focused on lifestyle interventions (Clinical Trial NCT04036006). Eligibility requirements included meeting diagnostic criteria for metabolic syndrome, absence of safety risks, psychiatric and serious illness, with demonstrated motivation for improving lifestyle. Self-report measures of EatC (ecSI 2.0), mindfulness (Five Facet Mindfulness Scale), stress (Cohen Perceived Stress), health related quality of life (HRQL; SF-36), and depressive symptoms (PHQ-8) were collected at baseline, 6 months, 15 months, and 24 months. The ecSI 2.0 changes were analyzed with GLM repeated measures corrected for non-sphericity, controlling for baseline mental health and well-being measures, sex, and intervention group i.e., monthly mailings of educational material (education) vs. 6-month small group habit-based lifestyle program (lifestyle). Changes in mindfulness, stress, depressive symptoms, HRQL and EatC were compared using Pearson correlation with Bonferroni correction for multiple comparisons.

Results: Of 618 study participants, 466 (76% female, 62% college educated, 70% white, mean age 55.9 ±10.6 y) completed ecSI 2.0 at all 4 time points. The ecSI 2.0 scores increased from 30.1 (SE 0.3) to 32.1 (SE 0.4) (P<0.001). Pattern of change differed by intervention group (P=0.006) with rapid increase for the intensive lifestyle group (n=227) vs gradual increase in the self-directed group (n=239). Except for stress, changes continued to be significant when controlling for baseline measures of mental health and well-being. Change in EatC from baseline to 6 months and to 24 months were significantly related to changes in HRLQ (P<0.001), mindfulness (P<0.001) and negatively related to changes in depressive symptoms (P<0.01) and stress (P<0.001).

Conclusion: Findings suggested that the ecSI 2.0, a validated, brief measure of EatC can be a marker of changes in mental health and HRQL over a 2y period. Further research is needed to understand the causal and/or consequential relationship between EatC and mental health, well-being status and HRQL.

II-P-N.12

Assessing the Relationship between Food Insecurity and Psychological Distress among College Students

Z. Qamar¹, S. Misra¹, J. Kwon¹, K. Boyce²

¹San Francisco State University, San Francisco, United States, ²University of California, San Francisco, San Francisco, United States

Purpose: Basic needs insecurity is a significant barrier to student health, well-being, and academic success. However, the relationship of food insecurity to dimensions of mental health, specifically flourishing and psychological distress, needs to be examined.

Methods: Using data from the Spring 2024 administration of the American College Health Association National College Health Assessment (ACHA-NCHA) at San Francisco State University, this study examined associations between validated measures of food insecurity, overall health, flourishing, and psychological distress among students (n=1354 students). Descriptive statistics and regression analyses were used to examine associations between levels of food insecurity and mental health outcomes.

Results: Results indicated that the majority of the students in the sample were female (61.7%), under 24 years of age (70%), and undergraduates (81.5%). The sample was representative of the diversity of students, with 34.6% Latinx, 23.3% Asian, 15.5% White, along other backgrounds. The majority of the students (62%) faced food insecurity. With regards to mental health variables, students experiencing any level of food insecurity reported poorer health and lower flourishing than food-secure peers. A gradient of psychological distress was also observed, with the most

N. MENTAL HEALTH AND WELLBEING

severe food insecurity associated with the highest distress.

Conclusion: These results highlight the need for comprehensive and targeted campus strategies to address both material and psychological dimensions of student well-being. By integrating basic needs programming with counseling and wellness resources, campuses can more effectively promote student flourishing, reduce inequities, and support retention and graduation.

II-P-N.13

Active Breaks and Well-being across the Lifespan: An Umbrella Review of Systematic Reviews with or without Meta-analysis

N. Pérez-Romero¹, K. Soto-Schulz¹, E. Cerda-Vega¹

¹Universidad Andrés Bello, Exercise and Rehabilitation Sciences Institute, Postgraduate, Faculty of Rehabilitation Sciences, Universidad Andres Bello, Santiago de Chile, Chile

Purpose: Short bouts of physical activity, or active breaks, are proposed as a way to reconfigure daily routines by embedding movement into otherwise sedentary contexts, potentially influencing multiple dimensions of well-being. While several systematic reviews have examined the effects of active breaks, a comprehensive synthesis of these reviews has not yet been conducted. The purpose of this umbrella review is to synthesize and critically evaluate existing systematic reviews on the effects of active breaks on subjective, psychological, and emotional well-being across diverse populations and settings, identify gaps in the literature, and highlight implications for practice and future research.

Methods: An umbrella review was conducted in accordance with PRIOR guidelines. A comprehensive search was performed in PubMed, Scopus, Web of Science, and Consensus from database inception to February 24, 2026. Systematic reviews with or without meta-analysis examining the effects of active breaks on subjective, psychological, or emotional well-being were included, in any age population. The primary outcomes were measures of well-being, including but not limited to stress, mood, psychological well-being, vitality, or quality of life. Study selection and data extraction were conducted using Rayyan.ai. Data were synthesized descriptively, reporting frequencies and key findings across reviews. Methodological quality of the reviews included was assessed using AMSTAR-2 and overlap was calculated in order with MoOR guide and reporting Corrected Covered Area. PROSPERO-ID: CRD420261325800

Results: Of a total of 65 studies, 9 were selected. Results show positive/mixed effects of active breaks on psychological well-being outcomes. In school-aged populations, reported outcomes included improvements in self-efficacy, emotional regulation, and perceived quality of life. Among adolescents, findings suggested benefits for vitality and school engagement. In workplace settings, micro-break interventions were associated with higher vigor and reduced fatigue. Across settings, reviews reported improvements in mood and perceived stress, although variability in intervention characteristics and contextual factor, such as autonomy in break-taking, appeared to influence effectiveness.

Conclusion: Active breaks may represent a feasible approach to support psychological and emotional well-being in sedentary contexts. However, heterogeneity in intervention design and outcome assessment limits comparability across studies. Future research should prioritize standardized reporting and examine implementation-related factors to inform scalable well-being promotion strategies.

II-P-N.14

Adherence to the 24-hour Movement Guidelines and Adolescents' Health-related Quality of Life and Wellbeing

T. Juřicová¹, D. Janda¹, J. Dygrýn², F. Chmelík², L. Rubín², C. Martins³, A. Gába¹

¹Palacký University, Department of Natural Sciences in Kinaanthropology, Olomouc, Czech Republic, ²Palacký University, Institute of Active Lifestyle, Olomouc, Czech Republic, ³University of Porto, Faculty of Sports, Porto, Portugal

Purpose: Movement behaviors play an important role in adolescents' health-related quality of life (HRQoL) and wellbeing. Most studies highlight the benefits of adherence to all movement guidelines, however the prevalence remains low. This study examines the associations of adherence to the movement guidelines with HRQoL and wellbeing in adolescents, with a particular focus on partial adherence.

Methods: This cross-sectional study included 979 Czech adolescents aged 10–18 years (55% girls). Physical activity

N. MENTAL HEALTH AND WELLBEING

(PA) and sleep were assessed using a wrist-worn accelerometer, screen time (ST) was self-reported. The PedsQL 4.0 was used to assess HRQoL, and subjective wellbeing was measured using the WHO-5 questionnaire. Associations between adherence to the movement guidelines and HRQoL (overall, physical and psychosocial dimensions) and wellbeing were examined using multivariate mixed-effects linear regression models.

Results: Nearly 41% of participants did not meet any movement guidelines. Compared with this group, those who adhered to the ST guideline had higher HRQoL ($\beta=4.3$, 95% confidence interval [CI]: 1.5–7.0) and higher wellbeing ($\beta=4.6$, 95% CI: 0.2–9.1). Adherence to the PA and ST guidelines was positively associated with HRQoL ($\beta=6.1$, 95% CI: 0.7–11.4) and wellbeing ($\beta=11.4$; 95% CI: 5.2–17.7). Higher HRQoL by 3.7 units (95% CI: 0.7–6.8) was observed among participants who adhered to PA and sleep guidelines. A significant association between adherence to the ST and sleep guidelines and HRQoL was also observed ($\beta=5.2$, 95% CI: 2.1–8.3). Participants who adhered to all movement guidelines had higher HRQoL by 13.2 units (95% CI: 8.0–18.3) and wellbeing by 11.5 units (95% CI: 0.7–22.3). The associations were generally similar across both dimensions of HRQoL.

Conclusion: Adherence to the movement guidelines was associated with better HRQoL and wellbeing. Although the highest scores were observed among adolescents adhering to all three guidelines, significant associations were also observed for individual guidelines. This implies that targeting individual behaviours, particularly ST, may represent a feasible starting point for increasing overall adherence to the guidelines and improving adolescents' HRQoL and wellbeing.

II-P-N.15

Compliance with the 24-hour Movement Behavior Guidelines and Mental Health in Brazilian Adolescents: Data from ActTeens Program

A. Stabelini Neto¹, G. Castilho dos Santos¹, G. Pinzon¹, A. Machado-Rodrigues², B. Gonçalves Galdino da Costa³

¹Universidade Estadual do Norte do Paraná, Health Sciences Center, Jacarezinho, Brazil, ²Universidade de Coimbra, Faculty of Sport Sciences and Physical Education, Coimbra, Portugal, ³McGill University, Department of Kinesiology and Physical Education, Montreal, Canada

Purpose: Mental illnesses are a growing concern in the field of public health, affecting large numbers of adolescents. Physical activity (PA), screen time (ST), and sleep duration (SLP) have been identified as modifiable behaviors that can improve adolescent mental health. Recognizing that the “whole day matters”, the Canadian 24-hour Movement Behavior Guidelines (24-HMB) provides recommendations on what a balanced day looks like. The purpose of the present study was to examine the associations between meeting the 24-HMB guidelines with anxiety, depression and stress symptoms among Brazilian adolescents.

Methods: A total of 1,151 adolescents (49% males, age 13.5±1.0 years old) participated in this cross-sectional study. PA, ST, and SLP were assessed through self-reported questionnaires. Depressive, anxiety, and stress symptoms were assessed using the DAS-21. Associations were tested using Generalized Linear Models, adjusted by age, sex, and BMI percentile.

Results: Concerning adherence to the 24-HMB guidelines, 21.5% of adolescents met the PA recommendation, while 25.2% met the ST, and 32.2% the SLP recommendations. Overall, 2.5% of the participants met the three 24-HMB guidelines, while 44.5% did not meet any. Adolescents who did not meet any of the recommendations presented highest symptoms of anxiety (11.5±10.6), depression (13.9±12.1), and stress (15.6±11.4) compared with their pairs who met some of them. Not meeting the PA recommendation was associated with higher depression symptoms ($\beta=1.18$; 95%CI=1.02-1.36), while not meeting the ST recommendation was associated with higher anxiety ($\beta=1.20$; 95%CI=1.05-1.38), depression ($\beta=1.19$; 95%CI=1.04-1.37), and stress symptoms ($\beta=1.21$; 95%CI=1.08-1.37). Finally, not meeting the SLP recommendation was associated with higher depression ($\beta=1.26$; 95%CI=1.12-1.42) and stress symptoms ($\beta=1.12$; 95%CI=1.01-1.24).

Conclusion: Meeting all three 24-HMB guidelines is associated with mental health benefits among Brazilian adolescents, and meeting specific ones is better than not meeting any. Therefore, programs should be created to raise awareness and encourage adolescents to adhere to public health guidelines.

The Association of Physical Activity and Muscular Strength with Adaptive and Cognitive Functioning in Adults with Down Syndrome. Preliminar Findings from the CogDown Study

J. Guerrero Moreno¹, A. Ruiz Tocino¹, M.T. Rodríguez Palacios², A. Coca-Pulido^{2,3}, P. Solis-Urra^{2,4,5}, J. Sánchez-Martínez^{2,3}, M. Cano Sánchez⁶, A. Catena Martínez⁷, I. Esteban-Cornejo^{2,8,9}, R. Izquierdo-Gómez^{1,10}

¹Universidad de Cádiz, GALENO Research group, Department of Physical Education, Faculty of Education Sciences, Cádiz, Spain, ²Universidad de Granada, Department of Physical Education and Sports, Granada, Spain, ³University Research Institute (iMUDS), Sport and Health, Granada, Spain, ⁴“Virgen de Las Nieves” University Hospital, Nuclear Medicine Services, Granada, Spain, ⁵Universidad Andres Bello, Faculty of Education and Social Sciences, Viña del Mar, Chile, ⁶Dirección CEPAP, Asociación Síndrome de Down, Granada, Spain, ⁷Universidad de Granada, Departamento de Psicología Experimental, Granada, Spain, ⁸Instituto de Salud Carlos III, Centro de Investigación Biomédica en Red Fisiopatología de la Obesidad y Nutrición, Madrid, Spain, ⁹Instituto de Investigación Biosanitaria ibs, Granada, Spain, ¹⁰Biomedical Research and Innovation Institute of Cádiz (INiBICA), Cádiz, Spain

Purpose: Adults with Down syndrome (DS) typically engage in lower levels of physical activity (PA) and present reduced muscular strength compared with the general population. DS is also associated with a high risk of Alzheimer’s disease-related cognitive impairment, making modifiable lifestyle factors relevant. In the general population, higher PA and greater muscular strength are consistently linked to better cognitive performance and functioning; however, evidence in adults with DS remains limited. Therefore, this study aimed to examine the associations of PA and muscular strength with adaptive and cognitive functioning in adults with DS.

Methods: Cross-sectional data from the CogDown study were collected in 2025–2026 from 31 adults (12 women) with DS (37.1 ± 6.9 years). PA was assessed using the short-form International Physical Activity Questionnaire (IPAQ-short form) completed by a proxy respondent (parent/caregiver). Muscular strength was measured via handgrip strength using a handheld dynamometer. Adaptive functioning was proxy-rated using the Adaptive Behavior Assessment System (ABAS-II). Cognitive functioning was assessed with the Modified Cued Recall Test (mCRT; total recall) and the Cambridge Cognitive Examination (CAMCOG; total score). Associations were examined using multiple linear regression models adjusted for age and sex. Standardized regression coefficients (β) and corresponding p-values are reported. Statistical significance was set at $p < 0.05$.

Results: Proxy-reported PA (walking, moderate PA, and total PA MET-min) was not associated with adaptive functioning (total score $p \geq 0.542$) or memory performance (mCRT total recall; all $p \geq 0.457$). Higher muscular strength showed a borderline association with adaptive functioning total score ($\beta = 0.542$, $p = 0.062$) and was positively associated with global cognitive performance (CAMCOG total score: $\beta = 0.501$, $p = 0.029$). PA metrics were not significantly related to CAMCOG (all $p \geq 0.078$).

Conclusion: In this preliminary cross-sectional sample, muscular strength showed stronger associations with global cognition than proxy-reported PA, with a trend for adaptive functioning. These findings suggest further investigation in larger samples and longitudinal follow-up to clarify the role of fitness and physical activity in this population.

II-P-N.17

Is Our Programming Consistent with the Satter Eating Competence and Feeding Dynamic Models? Development of the Rubric to Frame the Response

B. Lohse¹, E. Satter²

¹Rochester Institute of Technology, Wegmans School of Health and Nutrition, Rochester, United States, ²Ellyn Satter Institute, Madison, United States

Purpose: Describe a rubric used in program and nutrition education planning to guide and/or foster adherence to the Satter models of eating competence (ecSatter) and feeding dynamics (fdSatter). These evidence-based models present challenges for nutrition educators because they are nuanced and not congruent with standard nutrition recommendations, but rather emphasize structured availability of personally preferred food and trust in the effectiveness of biopsychosocial processes to guide nutritional status and body weight.

Methods: A narrative review of seminal publications on ecSatter, fdSatter, and research utilizing tools to measure adherence to these models informed the structure of the rubric. Detailed items, especially pertaining to inconsistencies in model usage, were formulated from clinical observations. The tenets of the models provided the rubric’s organization.

N. MENTAL HEALTH AND WELLBEING

Informal pilot testing with nutrition educators supported efforts toward further refinement and testing.

Results: A rubric is available to assess fidelity of interventions to ecSatter and fdSatter. The 110 Items are grouped according to 1) ecSatter tenets and components of Attitudes, Context, Food Acceptance, and Internal Regulation (43 items), fdSatter's division of responsibility in feeding of child autonomy and parent leadership for children younger than 12 years and 12 or older (19 items), identification of parent education practices inconsistent with ecSatter and fdSatter (9 items), nutrition education practices (25 items) and nutrition education actions inconsistent with ecSatter and fdSatter (14 items). The inclusion of model-consistent and inconsistent practices offers an opportunity for education. The current iteration of the rubric is formatted as a checklist with binary (yes/no) responses for model consistency. Items are phrased to encourage self-reflection and decisive responses.

Conclusion: The rubric is widely available at no cost and has been well-received as a valuable tool for developing ecSatter- and fdSatter-consistent materials and programming, as well as evaluating existing interventions and literature model adherence. The rubric offers potential to clarify ecSatter and fdSatter for educators, clinicians, and policy makers and ensure that research findings are correctly interpreted when ascribed to a Satter model.

II-P-N.18

Characterizing Diet-related Strategies for Pain Self-management in Endometriosis

C. Palmeira¹, M.L. Nunes^{2,3}, I. Santos^{2,4}, J. Encantado^{1,5,6}

¹ISPA - Instituto Universitário, Psychology, Lisbon, Portugal, ²Faculdade de Medicina, Universidade de Lisboa, Lisbon, Portugal, ³Fraunhofer Portugal AICOS & Comprehensive Health Research Center (CHRC), Porto, Portugal, ⁴Instituto de Saúde Ambiental, Faculdade de Medicina, Universidade de Lisboa, Lisbon, Portugal, ⁵CIPER - Centro Interdisciplinar para o Estudo da Performance Humana, Lisbon, Portugal, ⁶Faculdade de Motricidade Humana, Universidade de Lisboa, Lisbon, Portugal

Purpose:

Endometriosis affects approximately 10% of women of reproductive age and is frequently associated with chronic pain. Although medical treatments aim to control symptoms, pain relief is often partial or temporary, leading many women to adopt self-management strategies. Dietary changes have been associated with improved pain perception and quality of life; yet, little is known about how women integrate diet into everyday pain management. This study explores women's perspectives and experiences of managing endometriosis-related pain, and characterizes diet-related strategies used for pain self-management.

Methods: A qualitative interview study is underway (N=8 of an expected 15 adult women with a confirmed diagnosis of endometriosis and having implemented dietary changes following diagnosis). Semi-structured interview topics include endometriosis-related psychological and physical symptoms, self-management practices, healthcare support, and dietary changes, including perceived barriers and facilitators. A body-mapping exercise is used as an elicitation tool to document pain location, and to prompt discussion about its impact. Sociodemographic data are collected for sample characterization. Interviews are audio recorded, body maps digitalized, and interviews transcribed verbatim and thematically analyzed in MAXQDA (v22.8.0). Ethical approval was granted by the Lisbon Academic Medical Center Ethics Committee (No. 279/25).

Results: Preliminary findings indicate chronic pelvic pain as the predominant symptom, often accompanied by pain in the lower back, legs and head. Pain contributed to psychological distress, particularly through fear and anticipation of symptom flares. Participants commonly use localized heat, breathing techniques, meditation, and dietary tracking to identify symptom-triggering foods as self-management strategies. Early healthcare experiences were frequently described as invalidating; however, once referred to endometriosis-specialized care, participants described improved support from multidisciplinary teams. Most participants reported shifting toward an anti-inflammatory dietary pattern. Perceived barriers included lack of food options and social support, while key facilitators were encouragement and to feel recognized and understood by others.

Conclusion: This study will provide insight into women's experiences with endometriosis management and underscores diet as a meaningful element of pain self-management. Findings will inform patientcentered guidance and support the development of tools to assist women in managing endometriosis-related pain.

N. MENTAL HEALTH AND WELLBEING

II-P-N.19

Population Attributable Fractions of Common Mental Disorders Due to Suboptimal Diet and Other Lifestyle Behaviours: A Systematic Review

R. Orr¹, F. Jacka¹, A. O'Neil¹, E. Gamage¹, D. Ashtree¹, E. Todd¹, M. Lane¹, M. Lotfaliany Abrand Abadi², W. Marx¹

¹Deakin University, Food & Mood Centre, The Institute for Mental and Physical Health and Clinical Translation (IMPACT), School of Medicine, Barwon Health, Geelong, Australia, ²Deakin University, The Institute for Mental and Physical Health and Clinical Translation (IMPACT), School of Medicine, Barwon Health, Geelong, Australia

Purpose: Population attributable fractions (PAFs) quantify the proportion of a disease that could be prevented if a particular risk factor were eliminated and provide an interpretable metric for prevention planning. While PAFs exist estimating the proportion of depression and anxiety (the common mental disorders; CMDs) preventable by targeting suboptimal lifestyle behaviours, published estimates for behaviours such as suboptimal diet, physical inactivity, poor sleep, and tobacco smoking, are scattered and methodologically variable. We used a systematic review to synthesise these studies and to critically appraise the methodological approaches used to generate them.

Methods: A systematic search of MEDLINE Complete, EMBASE, PsycINFO, Global Health, and Health Policy Reference Centre was conducted from inception to 05 February 2026 for studies estimating PAFs (or equivalent metrics meeting the PAF definition) for depression and/or anxiety attributable to suboptimal diet, physical inactivity, poor sleep, and/or tobacco smoking in adults. Two reviewers independently screened titles/abstracts and full texts and extracted data; discrepancies were resolved with a third reviewer. Study quality was assessed using the Newcastle–Ottawa Scale and a PAF-focused appraisal tool. Due to substantial heterogeneity, findings could not be meta-analysed.

Results: The search yielded 1,585 records; 12 studies met inclusion criteria. Studies were conducted in high-income settings (including Australia, France, Canada, Norway, Sweden, the UK, the US, and a multi-country European sample), with sample sizes ranging from 218 to 170,726. Across all included estimates, CMD PAFs attributable to lifestyle behaviours ranged from -17.2% (95%CI: -34.6, -5.3) to 22% (95%CI: 3, 41), with marked variability in exposure and outcome definitions, covariate adjustment, and PAF estimation methods. Six studies were rated good quality, one fair, and five poor. Reporting of core inputs for PAF validity was often incomplete (e.g., formula used, exposure prevalence), limiting interpretability.

Conclusion: Few rigorous, transparently reported PAF estimates exist for CMDs attributable to suboptimal lifestyle behaviours. Despite variability, good quality estimates support the value of targeting lifestyle behaviours as prevention targets for CMDs. However, our study underscores the need for methodologically robust, standardised, and fully reported PAF analyses to better inform population-level CMD prevention and investment decisions.

II-P-N.20

Depression and Anxiety Attributable to Dietary Risk Factors: A Global Burden of Disease Lifestyle and Mental Disorders Taskforce (GLAD) Burden of Proof Study

R. Orr¹, F. Jacka¹, A. O'Neil¹, GLAD Taskforce

¹Deakin University, Food & Mood Centre, The Institute for Mental and Physical Health and Clinical Translation (IMPACT), School of Medicine, Barwon Health, Geelong, Australia

Purpose: The Global Burden of Disease (GBD) quantifies cause-specific health burden across countries and over time, and attributes burden to risks through comparative risk assessment using standardised exposure definitions. Diet is a major, actionable risk factor in the GBD for non-communicable diseases. Yet it is not currently included as a contributor to depression and anxiety (common mental disorders; CMDs) burden largely due to a lack of studies assessing these relationships using GBD-defined dietary categories. The Global burden of disease Lifestyle And mental Disorders (GLAD) Taskforce was established to generate harmonised, GBD-aligned lifestyle-CMD risk outcome estimates needed for inclusion in the GBD study by coordinating international cohorts to implement a common protocol using GBD-defined dietary exposures and CMD outcomes. The next stage is to conduct a meta-analysis to synthesise existing estimates of associations between GBD-defined dietary risks and CMD outcomes using the GBD Burden of Proof methodology.

Methods: This meta-analysis includes (i) GLAD member studies implementing the harmonised GLAD protocol and (ii) externally identified studies from systematic searches. Exposures are GBD-defined dietary risks, including low intake of fruits, vegetables, legumes, whole grains, nuts and seeds, milk, fibre, calcium, seafood omega-3, polyunsaturated

N. MENTAL HEALTH AND WELLBEING

fats, and high intake of red meat, processed meat, sugar-sweetened beverages, trans-fatty acids, and sodium. Outcomes are GBD-defined major depressive disorder and anxiety disorders. Records are screened and extracted using harmonised templates. Meta-analyses will apply the GBD Burden of Proof framework to estimate dose-response risk curves and derive conservative burden-of-proof risk (BPRF) functions and 1–5-star evidence ratings, accounting for outliers, heterogeneity, and small-study effects.

Results: Searching, screening, and harmonised data extraction are underway. The presentation will summarise study characteristics and provide preliminary BPRFs and evidence ratings.

Conclusion: This work will provide the first GBD-aligned Burden of Proof synthesis of dietary risks for depression and anxiety, integrating harmonised GLAD cohort analyses with systematically identified evidence. By standardising exposure and outcome definitions and applying Burden of Proof dose-response modelling, GLAD is designed to produce comparable, policy-relevant estimates to inform prevention-focused guideline development and future GBD risk attribution.

II-P-N.21

The Association between Sleep Quality and Adaptive and Cognitive Functioning in Adults with Down Syndrome. Preliminary Findings from the CogDown Study

A. Ruiz Tocino¹, J. Guerrero Moreno¹, M.T. Rodríguez Palacios², A. Coca-Pulido^{2,3}, P. Solis-Urra^{2,4,5}, J. Sánchez-Martínez^{2,3}, M. Cano Sánchez⁶, A. Catena Martínez², I. Esteban-Cornejo^{2,7,8}, R. Izquierdo-Gómez^{1,9}

¹Universidad de Cádiz, GALENO Research Group, Departament of Physical Education, Faculty of Education Sciences, Cádiz, Spain, ²Universidad de Granada, Departament of Physical Education and Sports, Granada, Spain, ³University Research Institute (iMUDS), Sport and Health, Granada, Spain, ⁴“Virgen de Las Nieves” University Hospital, Nuclear Medicine Services, Granada, Spain, ⁵Universidad Andres Bello, Faculty of Education and Social Sciences, Viña del Mar, Spain, ⁶Dirección CEPAP, Asociación Síndrome de Down, Granada, Spain, ⁷Instituto de Salud Carlos III, Centro de Investigación Biomédica en red Fisiopatología de la Obesidad y Nutrición, Madrid, Spain, ⁸Instituto de Investigación Biosanitaria ibs, Granada, Spain, ⁹Biomedical Research and Innovation Institute of Cádiz (INiBICA), Cádiz, Spain

Purpose: Adults with Down syndrome (DS) frequently experience sleep disturbances, particularly sleep fragmentation and obstructive sleep apnoea, often under-recognised despite their impact on daytime functioning and health. DS is also associated with a very high lifetime risk of Alzheimer’s disease, making identification of modifiable correlates of cognitive outcomes relevant. Emerging evidence in non-demented adults with DS suggests that poorer sleep (e.g., reduced sleep efficiency) relates to Alzheimer’s disease pathology and worse cognitive performance. Thus, the main aim of this study was to examine the association of subjective sleep quality and adaptive and cognitive functioning in adults with DS.

Methods: This preliminary cross-sectional analysis used data from the CogDown study collected in 2025–2026. A total of 31 adults (12 women) with DS participated (37.1 ± 6.9 years). Sleep quality was assessed with the Pittsburgh Sleep Quality Index (PSQI) completed by a proxy respondent (parent/caregiver). Adaptive functioning was measured using the Adaptive Behavior Assessment System (ABAS-II), also proxy-completed. Cognitive functioning was evaluated directly using standardized assessments, including the Modified Cued Recall Test (mCRT; memory) and the Cambridge Cognitive Examination (CAMCOG; global cognition). Associations of sleep quality and adaptive and cognitive functioning were examined using multiple linear regression models adjusted for age and sex. Significance was set at p<0.05.

Results: Sleep quality was not associated with adaptive functioning (ABAS-II total score: $\beta=-0.057$, p=0.816). Poorer sleep quality (higher scores indicating poorer sleep) was associated with lower memory performance on the mCRT ($\beta=-0.600$, p=0.008), whereas the association with global cognitive performance was not significant (CAMCOG total score: $\beta=-0.190$, p=0.479).

Conclusion: In this preliminary cross-sectional analysis from the CogDown study, greater sleep disturbances were associated with poorer memory performance, but not with adaptive or general cognitive functioning in adults with DS. These findings support further investigation in larger samples and longitudinal follow-up to clarify the role of sleep in cognitive health in DS.

N. MENTAL HEALTH AND WELLBEING

II-P-N.22

Intuitive Eating and Psychological Indicators among College Students

S. Matias¹

¹University of California, Berkeley, Metabolic Biology & Nutrition, Berkeley, United States

Purpose: To determine whether intuitive eating was associated with psychological indicators among young adults.

Methods: A sample of 144 undergraduate students completed an anonymous online survey. Several validated scales were included in the survey to measure the study variables. Intuitive eating was assessed using three subscales of the Intuitive Eating Scale-2: *physical rather than emotional eating*, *hunger and satiety cues reliance*, and *body-food choice congruence*. Psychological indicators assessed included: *wellbeing* (8-item Flourishing Scale), *stress* (Perceived Stress Scale, PSS-10), *anxiety risk* (Generalized Anxiety Disorder screener, GAD-2), and *depression risk* (Patient Health Questionnaire, PHQ-2). Linear regression models were used to test associations between intuitive eating scores and wellbeing and stress scores; and logistic regression was used to test their association with anxiety and depression risk. Models were adjusted for gender and race/ethnicity. Statistical significance was set at <0.05 .

Results: Mean ($\pm$ SD) scores for physical rather than emotional eating, hunger and satiety cues reliance, and body-food choice congruence subscales were: 2.98 (0.88), 3.39 (0.96) and 3.56 (0.95), respectively. Eighty-five (60.3%) were categorized as at risk of anxiety and 53 (37.6%) fell in the at risk of depression category. Intuitive eating subscale scores were significantly associated with each psychological indicator.

Physical rather than emotional eating was positively associated with wellbeing ($p=0.004$) and negatively associated with stress ($p<0.001$). A similar pattern was observed for hunger and satiety cues reliance (wellbeing: $p=0.010$ and stress: $p=0.023$) and body-food choice congruence (wellbeing: $p<0.001$ and stress: $p=0.002$, respectively). A 1-point increase in physical rather than emotional eating score was associated with reduced odds of risk of anxiety (Odds ratio: 0.64, 95% Confidence Interval: 0.42, 0.97), but its association with risk of depression was not statistically significant. Scores in the other intuitive eating subscales were not significantly associated with any of the two dichotomous outcomes either.

Conclusion: Findings suggest that including an intuitive eating approach in health promotion interventions for college students (or young adults) may support their psychological wellbeing, while also promoting a healthy relationship with food.
